We perform a study of gravitational waves emitted by inspiraling black holes in the context of quadratic gravity. By linearizing the field equations around a flat background, we demonstrate that all degrees of freedom satisfy wavelike equations. These degrees of freedom split into three modes: a massive spin-2 mode, a massive spin-0 mode, and the expected massless spin-2 mode. We construct the energy-momentum tensor of gravitational waves and show that, due to the massive spin-2 mode, it presents the Ostrogradsky instability. We also show how to deal with this possible pathology and obtain consistent physical interpretations for the system. Using the energy-momentum tensor, we study the influence of each massive mode in the orbital dynamics and compare it with the standard result of general relativity. Moreover, we present two methods to constrain the parameter \( \alpha \) associated with the massive spin-2 contribution. From the first method, using the combined waveform for the spin-2 modes, we obtain the constraint \( \alpha \lesssim 1.1 \times 10^{21} \text{m}^2 \). In the second method, using the coalescence time, we get the constraint \( \alpha \lesssim 1.1 \times 10^{13} \text{m}^2 \).

I. INTRODUCTION

The direct detections of gravitational waves (GWs) by the LIGO-VIRGO collaboration, first in 2015 due to the collision of two black holes and then in 2017 due to the collision of two neutron stars, is one of the main results in the history of general relativity (GR) [1,3]. These detections not only observationally confirm one of the fascinating results of GR but also make it possible to obtain a deeper understanding of the gravitational interaction. In addition to the direct detections, GWs had already been indirectly observed through neutron star binary systems. In the 1970s, Hulse and Taylor observed a decrease in the orbital period of the PSR 1913+16 system [4], entirely consistent with the energy and momentum losses predicted by GR theory due to GWs emission [5,6].

Despite these and several other experimental results supporting the GR, there is a consensus in the scientific community that it is an incomplete theory. In addition to some structural problems within the theory, such as the presence of singularities, the GR also presents problems when analyzed in the context of high-energy physics. General relativity cannot be quantized through the conventional methods of particle physics [7,8], and it struggles to describe the early (inflationary) universe consistently [9,10].

One of the main ways of establishing observational constraints in theories of modified gravity is through the analysis of GWs [32–35]. However, with the new era of GWs detection, the analysis of modified theories in contexts of gravitational waves [36–41] is also of great interest, even allowing the determination of parameters in new scales different from those probed in cosmology [42,43].

In this spirit, we analyze the quadratic gravity model given by the action [11] in the context of the emission of gravitational waves:

\[
S = \int d^4x \sqrt{-g} \left[ R + \frac{1}{2} \gamma R^2 - \frac{1}{2} \alpha \mathcal{C}_{\mu \nu \alpha \beta} \mathcal{C}^{\mu \nu \alpha \beta} \right] - 2 \kappa \int d^4x \sqrt{-g} \mathcal{L}_m,
\]

where \( \mathcal{C}_{\mu \nu \alpha \beta} \) is the energy-momentum tensor of gravitational waves and \( \alpha \) is a parameter associated with the massive spin-2 contribution. From the first method, using the combined waveform for the spin-2 modes, we obtain the constraint \( \alpha \lesssim 1.1 \times 10^{21} \text{m}^2 \). In the second method, using the coalescence time, we get the constraint \( \alpha \lesssim 1.1 \times 10^{13} \text{m}^2 \).
where \( \kappa = \frac{8\pi G}{c^4} \), \( \alpha, \gamma \) are coupling constants with the dimension of \((\text{length})^2\) and \( C_{\mu\nu\alpha\beta} \) is the Weyl tensor.

Quadratic gravity is embedded in a context of higher-order gravity theories where higher energy corrections are inserted in the action. In this context, the Einstein-Hilbert term and the cosmological constant are zero-order terms (squared mass terms), the invariants \( R^2 \) and \( C_{\mu\nu\alpha\beta} C^{\mu\nu\alpha\beta} \) are first-order corrections \( \left( \text{fourth mass terms} \right) \), quantities of the type \( \Box R, C_{\mu\nu\alpha\beta} \Box C^{\mu\nu\alpha\beta} \) plus cubic terms in the Riemann tensor are second-order corrections (sixth mass terms), etc. Thus, this work aims to study how first-order corrections to general relativity influence the emission of GWs emitted by binary systems. More specifically, we study the emission of GWs produced by the inspiral phase of a binary black hole system in the approximations of point masses, circular orbit, and nonrelativistic dynamics.

The paper has the following structure: in Sec. II, we carry out the linearization of the field equation decomposing the metric into three new fields: a massless spin-2 field, as in GR; a massive spin-2 field, and a massive spin-0 field. Next, we analyze the gauge conditions that allow us to reduce the degrees of freedom of these new fields significantly. In the Sec. III we obtain the Green’s functions for the massive fields and carefully analyze the multipolar expansion for each field. In Sec. IV the solutions of the fields in terms of the multipolar expansions are applied to a binary system of point masses in circular orbits and the power radiated by the GWs is obtained. With that, in Sec. V the effect of the emission of GWs is analyzed using the energy balance equation, so that the inspiral phase is studied in terms of the orbital frequency of the system. In addition, Ostrogradsky’s instability, generated by the Weyl-Weyl term, is carefully analyzed in this section, and then it is shown how this apparent pathology can be suppressed and corrected. In light of this apparent pathology, we discuss in Sec. VI the role that spin-2 fields play in the emission of GWs, mainly explaining the differences and similarities between these fields, such as their propagation velocities and waveforms. With this, we establish some observational constraints. Finally, we end with the final comments in the Sec. VII.

II. QUADRATIC GRAVITY IN THE WEAK-FIELD REGIME

The field equation is obtained from (1) by varying it with respect to \( g^{\mu\nu} \):

\[
R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R + \gamma \left[ R \left( R_{\mu\nu} - \frac{1}{4} R g_{\mu\nu} \right) + g_{\mu\rho} \nabla^\rho R - \nabla_\mu \nabla_\nu R \right] - \alpha \left[ \nabla^\rho \nabla^\beta C_{\rho\mu\nu\beta} + \frac{1}{2} R^{\rho\beta} C_{\rho\mu\nu\beta} \right] = \kappa T_{\mu\nu}
\]

with the Riemann and Weyl tensors defined as

\[
R^\kappa_{\mu\nu\beta} \equiv \partial_\kappa \Gamma^\kappa_{\nu\beta} - \partial_\beta \Gamma^\kappa_{\nu\beta} + \Gamma^\kappa_{\rho\kappa} \Gamma^\rho_{\nu\beta} - \Gamma^\kappa_{\rho\beta} \Gamma^\rho_{\nu\kappa},
\]

\[
C_{\mu\nu\alpha\beta} \equiv R_{\mu\nu\alpha\beta} - \frac{1}{2} (g_{\mu\alpha} R_{\nu\beta} - g_{\nu\beta} R_{\mu\alpha} + g_{\nu\beta} R_{\alpha\mu} - g_{\alpha\mu} R_{\nu\beta}) + \frac{1}{6} R (g_{\mu\alpha} g_{\beta\nu} - g_{\mu\beta} g_{\alpha\nu}).
\]

In addition, the trace of the field equation (2) is

\[
3\gamma \nabla^\rho R - R = \kappa T.
\]

The linearized equations on a flat background for quadratic gravity were obtained in Ref. [50]. However, we will retrieve these equations using a clearer and more simplified approach. We start by decomposing the metric as

\[
g_{\mu\nu} = \eta_{\mu\nu} + h_{\mu\nu},
\]

where \( h_{\mu\nu} \ll 1 \). From the definition of the trace-reverse tensor \( h_{\nu\beta} = h_{\nu\beta} - \frac{1}{2} \eta_{\nu\beta} \bar{h} \), we obtain in linear order

\[
\]

\[
C_{\mu\nu\alpha\beta}^{(1)} = \frac{1}{2} \left[ \partial_\alpha \partial_\nu \bar{h}_{\mu\beta} - \partial_\beta \partial_\nu \bar{h}_{\mu\alpha} + \partial_\beta \partial_\mu \bar{h}_{\nu\alpha} - \partial_\alpha \partial_\mu \bar{h}_{\nu\beta} \right]
\]

\[
- \frac{1}{4} \eta_{\mu\alpha} \left( \partial_\beta \partial_\nu \bar{h}_{\rho\beta} - \partial_\beta \partial_\rho \bar{h}_{\nu\beta} + \partial_\rho \partial_\nu \bar{h}_{\beta\rho} - \Box \bar{h}_{\nu\beta} \right)
\]

\[
+ \frac{1}{4} \eta_{\nu\beta} \left( \partial_\alpha \partial_\mu \bar{h}_{\rho\alpha} - \partial_\alpha \partial_\rho \bar{h}_{\mu\alpha} + \partial_\rho \partial_\mu \bar{h}_{\alpha\rho} - \Box \bar{h}_{\mu\alpha} \right)
\]

\[
+ \frac{1}{4} \eta_{\nu\alpha} \left( \partial_\beta \partial_\mu \bar{h}_{\rho\beta} - \partial_\beta \partial_\rho \bar{h}_{\mu\beta} + \partial_\rho \partial_\mu \bar{h}_{\beta\rho} - \Box \bar{h}_{\mu\beta} \right)
\]

\[
+ \frac{1}{6} \left[ \partial_\alpha \partial_\mu \bar{h}_{\rho\beta} - \partial_\beta \partial_\rho \bar{h}_{\mu\beta} \right].
\]
and

\[ R^{(1)}_{\mu\nu} \approx \frac{1}{2} \left( \partial_{\rho} \partial_{\sigma} \tilde{h}_{\mu\nu}^{\rho} + \partial_{\rho} \partial_{\sigma} \tilde{h}_{\mu\nu}^{\rho} - \Box \tilde{h}_{\mu\nu} + \frac{1}{2} \eta_{\mu\nu} \Box \tilde{h} \right), \]

(7)

\[ R^{(1)} \approx \partial_{\sigma} \partial_{\rho} \tilde{h}^{\sigma\rho} + \frac{1}{2} \Box \tilde{h} \]

(8)

where \( \Box \equiv \partial_{\sigma} \partial^{\sigma} \) and \( \tilde{h} \equiv \tilde{h}_{\alpha\alpha} \).

The objective is to obtain wave equations for the various degrees of freedom of the metric in quadratic gravity. We start by defining the dimensionless scalar quantity \( \Phi \equiv -\gamma R^{(1)} \). In this case, the linearized equation \( \Box \) can be written as

\[ (\Box - m_{\Phi}^{2}) \Phi = -\frac{\kappa T}{3}, \]

(9)

where \( m_{\Phi}^{2} = 1/ (3\gamma) \) and \( T \) is the trace of \( T_{\mu\nu} \) in its linearized form. Then we decompose the metric into a scalar part and a tensorial part \([51, 52]\)

\[ \tilde{h}_{\mu\nu} = \Theta_{\mu\nu} - \eta_{\mu\nu} (\Phi + \phi) \]

(10)

with \( \phi \) representing an auxiliary gauge field. Furthermore, for the spin-2 part, we adopt the gauge

\[ \partial^\nu \Theta_{\mu\nu} = 0 \Rightarrow \partial^\nu \tilde{h}_{\mu\nu} = -\partial_\mu (\Phi + \phi). \]

(11)

Substituting the decomposition \([10]\) in the linearized equation \([2]\) we get

\[ \Box \Theta_{\mu\nu} + 2 \partial_\mu \partial_\nu \phi - 2 \eta_{\mu\nu} \Box \phi + 2 \alpha \partial^\nu \partial^\beta C^{(1)}_{\mu\nu\alpha\beta} = -2 \kappa T_{\mu\nu}. \]

(12)

The next step is to separate the tensorial component into a massive and a nonmassive mode:

\[ \Theta_{\mu\nu} = \tilde{h}_{\mu\alpha} + \Psi_{\mu\alpha}, \]

(13)

where we impose that the nonmassive mode \( \tilde{h}_{\mu\alpha} \) satisfies the equation

\[ \Box \tilde{h}_{\mu\alpha} = -2 \kappa T_{\mu\alpha}. \]

(14)

Thus, Eq. \([12]\) can be rewritten as

\[ \Box \Psi_{\mu\nu} + 2 \partial_\mu \partial_\nu \phi - 2 \eta_{\mu\nu} \Box \phi + 2 \alpha \partial^\nu \partial^\beta C^{(1)}_{\mu\nu\alpha\beta} = 0. \]

(15)

Then, we use the decomposition of the metric in the Weyl tensor and calculate \( \partial^\nu \partial^\beta C^{(1)}_{\mu\nu\alpha\beta} \) obtaining

\[ \partial^\nu \partial^\beta C^{(1)}_{\mu\nu\alpha\beta} = -\frac{1}{4} \Box^2 \left( \tilde{h}_{\mu\alpha} + \Psi_{\mu\alpha} \right) + \frac{1}{12} \eta_{\mu\nu} \Box^2 \left( \tilde{h} + \Psi \right) - \frac{1}{12} \partial_\alpha \partial_\mu \Box \left( \tilde{h} + \Psi \right), \]

where \( \tilde{h} = \tilde{h}_\alpha^\alpha \) and \( \Psi = \Psi_\alpha^\alpha \).

Once \( \partial^\nu \partial^\beta C^{(1)}_{\mu\nu\alpha\beta} \) has been calculated, we substitute this result in \([15]\) and choose the gauge field \( \phi \) as

\[ \phi = \frac{\alpha}{3} \Box \left( \tilde{h} + \Psi \right). \]

(16)

So, Eq. \([15]\) is rewritten as

\[ \Box \left[ \Psi_{\mu\nu} - \frac{\alpha}{2} \Box \left( \tilde{h}_{\mu\alpha} + \Psi_{\mu\alpha} \right) \right] = 0. \]

(17)

For trivial boundary conditions (e.g. fields vanishing at infinity), the above equation is satisfied only if the term in square brackets is null. In this case, using Eq. \([14]\) we get

\[ (\Box - m_{\Psi}^{2}) \Psi_{\mu\nu} = 2 \kappa T_{\mu\alpha}, \]

(18)

where \( m_{\Psi}^{2} = 2/\alpha \). From the field equations \([14]\) and \([18]\) we can show that the gauge conditions \([11]\) and \([16]\) result in

\[ \partial^\mu \Psi_{\mu\nu} = 0, \ \partial^\mu \tilde{h}_{\mu\nu} = 0 \quad \text{and} \quad \phi = \frac{1}{3} \Psi. \]

(19)

Therefore, the decomposition of the metric in the form

\[ \tilde{h}_{\mu\nu} = \tilde{h}_{\mu\nu} + \Psi_{\mu\nu} - \eta_{\mu\nu} \left( \Phi + \frac{1}{3} \Psi \right), \]

(20)

and the choice of gauge \([19]\) result in the Eqs. \([9]\), \([14]\) and \([18]\) associated with massive spin-0, massless spin-2 and massive spin-2 degrees of freedom, respectively.

### A. Degrees of freedom

As in general relativity, the conditions given in \([19]\) do not completely fix the gauge. Performing an infinitesimal coordinate transformation

\[ x^\mu = x^\mu + \xi^\mu (x), \]

it is possible to show that the full spin-2 mode transforms as

\[ \Theta'_{\mu\nu} = \Theta_{\mu\nu} - \partial_\mu \xi_\nu - \partial_\nu \xi_\mu + \eta_{\mu\nu} \partial^\beta \xi_\beta. \]

(21)

Taking the divergence of the expression above, we notice that any transformation \( \xi_\nu \) that respects \( \Box \xi_\nu = 0 \) maintains the harmonic gauge \( \partial^\mu \Theta_{\mu\nu} = 0 \). This residual
The physical solution of Eq. (14) is well known and given by
\[
\tilde{h}_{\mu\nu}(t_r, x) = \frac{\kappa}{2\pi} \int d^3 x' \frac{1}{|x - x'|} T_{\mu\nu}(t_r, x'),
\]
where \(t_r = t - \frac{|x - x'|}{c}\) is the retarded time and \(x\) (the vector \(x'\)) points from the origin of the coordinate system to the observer (to the source). The formal solutions to the equations (18) and (9) are given by
\[\Phi(\mathbf{x}, t) = -\frac{\kappa}{3} \int G_\Phi(\mathbf{x}'; \mathbf{x}'') T(\mathbf{t}', \mathbf{x}') d^4 \mathbf{x}'',\]
\[\Psi_{\mu\nu}(\mathbf{x}, t) = 2\kappa \int G_\Psi(\mathbf{x}'; \mathbf{x}'') T_{\mu\nu}(\mathbf{t}', \mathbf{x}') d^4 \mathbf{x}'.\]
The retarded Green’s functions that appear in the previous equations are described by the expression

$$G_X(x^\mu; x'^\mu) = -\frac{1}{4\pi c s} \frac{1}{c} \left( \frac{x - s}{s} \frac{1}{c} \right) + \frac{\frac{m_X}{\sqrt{r^2 - \left(\frac{s}{c}\right)}} J_1}{\sqrt{r^2 - \left(\frac{s}{c}\right)^2}} \Theta \left( \frac{r - s}{c} \right),$$

where $$\tau = t - t', s = |x - x'|$$, and $$X$$ represents $$\Phi$$ or $$\Psi$$. The function $$\Theta$$ is the Heaviside step function and $$J_1$$ is the Bessel function of the first kind. Details on the deduction of Eq. (27) can be seen in Appendix A of Ref. [45].

Substituting Green’s function in Eqs. (25) and (26) and considering large distances from the source, i.e. $$s \simeq |x| \equiv r$$, we get

$$\Phi(x, t) = \frac{\kappa}{12\pi r} \int T(x', t_r) d^3x' - \frac{m_\Phi}{12\pi} \int d^3x' \int_{\tau}^{\infty} d\tau \frac{J_1(m_\Phi c \sqrt{\tau^2 - \left(\frac{s}{c}\right)^2})}{\sqrt{\tau^2 - \left(\frac{s}{c}\right)^2}} T(x', t - \tau)$$

and

$$\Psi_{ij}(x, t) = -\frac{\kappa}{2\pi r} \int d^3x' T_{ij}(x', t_r) + \frac{m_\Phi}{2\pi} \int d^3x' \int_{\tau}^{\infty} d\tau \frac{J_1(m_\Phi c \sqrt{\tau^2 - \left(\frac{s}{c}\right)^2})}{\sqrt{\tau^2 - \left(\frac{s}{c}\right)^2}} T_{ij}(x', t - \tau).$$

Note that by the degrees of freedom of $$\Psi_{\mu\nu}$$ it is enough to calculate its spatial components. See Sec. II A. The next step is to perform the multipolar expansion for the fields $$\tilde{h}_{\mu\nu}, \Phi$$ and $$\Psi_{ij}$$. The multipolar expansion for the massless spin-2 field is well known from GR. The expansion procedure for the scalar field was deduced in Ref. [45] and results in

$$\Phi(x, t) = \Phi^M(x, t) + \Phi^D(x, t) + \Phi^Q(x, t) + \ldots,$$

where the monopole ($$M$$), dipole ($$D$$), and quadrupole ($$Q$$) contributions are given by

$$\Phi^M(x, t) = \frac{\kappa}{12\pi r} \left[ c^2M(t_r) \right] - \frac{m_\Phi}{12\pi} \kappa \int_0^{\infty} d\tau \Phi(t\tau) \left[ c^2M(\zeta) \right],$$

$$\Phi^D(x, t) = \frac{\kappa}{12\pi r} \left[ \frac{\partial M^i}{\partial t} \right]_{t_r} - \frac{m_\Phi}{12\pi} \kappa \int_0^{\infty} d\tau \Phi(t\tau) \left[ c_n \frac{\partial M^i}{\partial t} \right]_{t\zeta},$$

$$\Phi^Q(x, t) = \frac{\kappa}{12\pi r} \left[ \frac{1}{2} n_in_j \frac{\partial^2 M^{ij}}{\partial t^2} \right]_{t_r} - \frac{m_\Phi}{12\pi} \kappa \int_0^{\infty} d\tau \Phi(t\tau) \left[ \frac{1}{2} n_in_j \frac{\partial^2 M^{ij}}{\partial t^2} \right]_{t\zeta},$$

with the unit vector $$n^i$$ pointing along the $$x^i$$ direction, $$\zeta = t - \zeta$$, and

$$F_\Phi(t\tau) = \frac{J_1(m_\Phi c \sqrt{t^2 - \left(\frac{s}{c}\right)^2})}{\sqrt{2\tau c \sqrt{t^2 - \left(\frac{s}{c}\right)^2}}}. \quad (33)$$

The mass moments built with the trace of the energy-momentum tensor are defined as

$$\mathcal{M}(t) = \frac{1}{c^2} \int d^3x' T(x', t),$$

$$\mathcal{M}^i(t) = \frac{1}{c^2} \int d^3x' T(x', t) x^i,$$

$$\mathcal{M}^{ij}(t) = \frac{1}{c^2} \int d^3x' T(x', t) x^i x^j.$$
The multipolar expansion for the massive spin-2 field follows similar steps to those performed for the \( \Phi \) field. Thus, we get
\[
\Psi_{ij} (x, t) = \frac{\kappa}{2\pi} \left[ -\frac{1}{r} S_{ij} (t_r) + m_\Psi \int_0^\infty dt_r F_\Psi (t_r) S_{ij} (\zeta) - \frac{1}{r} \frac{\partial S^{ij,k}}{\partial t_r} \bigg|_{t_r} \right] + m_\Psi \int_0^\infty dt_r F_\Psi (t_r) \frac{\partial S^{ij,k}}{\partial t_r} \bigg|_{\zeta} + ..., \]
where \( F_\Psi (t_r) \) is given by Eq. (33) switching \( m_\Psi \to m_\Phi \). The first two moments of the stress tensor \( T^{ij} \) are defined as
\[
S^{ij} (t) \equiv \int d^3 \mathbf{x}' T^{ij} (x', t),
\]
and
\[
S^{ij,k} (t) \equiv \int d^3 \mathbf{x}' T^{ij} (x', t) x^k.\]
Furthermore, the first moment \( S^{ij} \) can be written as \( S^{ij} = \frac{1}{2} M^{ij} \), where
\[
M^{ij} = \frac{c^2}{4\pi} \int d^3 \mathbf{x}' T^{00} (x', t) x^i x^j
\]
is the usual quadrupole mass moment of general relativity.

Therefore, using the traceless-transverse (TT) gauge for \( h_{\mu\nu} \) and taking into account only the dominant terms of each mode, we have
\[
\left[ \ddot{h}_{ij}^{TT} (x, t) \right]_Q = \frac{1}{r} \frac{\kappa}{4\pi} \Lambda_{ij,kl} (\hat{\mathbf{n}}) \ddot{M}^{kl} (t_r), \tag{38}
\]
\[
\left[ \Psi_{ij} (x, t) \right]_Q = -\frac{1}{r} \frac{\kappa}{4\pi} \ddot{M}_{ij} (t_r) + \frac{\kappa}{4\pi} m_\Psi \int_0^\infty dt_r F_\Psi (t_r) \ddot{M}_{ij} (\zeta), \tag{39}
\]
where \( \Lambda_{ij,kl} \) is a projection tensor that selects the TT gauge [54]. We will see in the next section that for a binary system with nonrelativistic dynamics \( \Phi^{D} = 0 \), and thus the dominant term of the scalar part will also be a quadrupole term.

### IV. Binary System in Circular Orbit

We begin by writing the energy-momentum tensor for a nonrelativistic binary point-mass system \( m_A \) in the center-of-mass frame:
\[
T_{\mu\nu} = \sum_{A=1}^2 m_A c^2 \delta^{(0)} (x - x_A (t)),
\]
where \( x_A (t) \) is the vector representing the trajectory of particle \( A \). From this energy-momentum tensor and its trace, we can calculate the mass moments for spin-0 and spin-2 modes in the center-of-mass (c.m.) frame. So, by Eqs. (34), (35), (36), and (37) we get
\[
\mathcal{M} (t) = -m, \quad \mathcal{M}^i (t) = 0 \quad \text{and} \quad \mathcal{M}^{ij} (t) = -\mu x_0^i (t) x_0^j (t) = -M^{ij} (t), \tag{41}
\]
where \( m = m_1 + m_2 \) is the total mass, \( \mu = m_1 m_2 / m \) is the reduced mass and \( x_0^i (t) \) is the relative coordinate \( x_0 = x_1 - x_2 \). The above expression shows that the monopole and dipole contributions to the spin-0 mode are zero. This result reflects the conservation of mass and linear momentum of a nonrelativistic binary system.

The next step is to determine the trajectory \( x_0^i (t) \). For simplicity, we will consider a circular orbit of radius \( R \) and angular frequency \( \omega_s \) positioned along the XY-plane. In this case, the relative coordinate is given by
\[
x_0^i (t) = \left( R \cos \left( \omega_s t + \frac{\pi}{2} \right), R \sin \left( \omega_s t + \frac{\pi}{2} \right), 0 \right), \tag{42}
\]
and the unit vector \( n_{i,M} = (0, 0, 1) \). Note that as the orbit is restricted to the XY-plane, the mass moments \( M^{13} = M^{31} = M^{33} = 0 \), which implies \( \Psi_B = \Psi_C = \Psi_D = 0 \). Thus, of the 5 degrees of freedom associated with \( \Psi_{ij} \), only the transverse modes \( \Psi_+ \) and \( \Psi_\times \) are produced.

By fixing the coordinate system at the observer’s point of view, we can decompose the unit vector \( n^i \) in terms of the polar angle \( \theta \) and the azimuthal angle \( \phi \) as
\[
n^i = (\sin \theta \sin \phi, \sin \theta \cos \phi, \cos \theta). \]
In this reference frame, \( \phi \) represents a phase in the XY-plane, and \( \theta \) is the angle between the normal of the orbit plane and the line of sight. For more details, see Figs. 3.2 and 3.6 of Ref. [54].

The spin-0, massive spin-2, and massless spin-2 modes are obtained by substituting the moments \( M^{ij} \) and \( \mathcal{M}^{ij} \) present in Eq. (38), (39), (40), and (42), and then calculating the integrals that contain the functions \( F_0 \) and \( F_\phi \). The calculation of these integrals is not trivial and can be found in Appendix B of Ref. [54]. Carrying out all these calculations, considering the chirp mass \( M_c = m^{3/2} \mu^2 \) and the Kepler’s third law \( \omega_s^2 = Gm / R^3 \), we obtain
for massless tensorial modes,

\[ \Psi_+ (x, t) = \begin{cases} 
-4c \left( \frac{GM_c}{c^3} \right) \frac{2}{3} \omega_s^{2/3} \cos \left( 2\omega_s t + 2\phi \right) \exp \left[ -m_{\phi} r \sqrt{1 - \left( \frac{2w_s}{m_{\phi} c} \right)^2} \right], & 2\omega_s < m_{\phi} c \\
-4c \left( \frac{GM_c}{c^3} \right) \frac{2}{3} \omega_s^{2/3} \cos \left( 2\omega_s t + 2\phi \right) \exp \left[ -m_{\phi} r \sqrt{1 - \left( \frac{2w_s}{m_{\phi} c} \right)^2} \right], & 2\omega_s > m_{\phi} c
\end{cases} \]

for the massive tensorial modes and

\[ \Phi (x, t) = \begin{cases} 
4c \left( \frac{GM_c}{c^3} \right) \frac{2}{3} \omega_s^{2/3} \sin^2 \theta \cos \left( 2\omega_s t + 2\phi \right) \exp \left[ -m_{\phi} r \sqrt{1 - \left( \frac{2w_s}{m_{\phi} c} \right)^2} \right], & 2\omega_s < m_{\phi} c \\
4c \left( \frac{GM_c}{c^3} \right) \frac{2}{3} \omega_s^{2/3} \sin^2 \theta \cos \left( 2\omega_s t + 2\phi \right) \exp \left[ -m_{\phi} r \sqrt{1 - \left( \frac{2w_s}{m_{\phi} c} \right)^2} \right], & 2\omega_s > m_{\phi} c
\end{cases} \]

for massive scalar mode.

The most relevant point of the solutions above is that the massive modes have two distinct regimes. The first of these is a damping regime that occurs when \(2\omega_s < m_{\phi} c\). In this regime we do not have a wave solution, and the massive modes only contribute with a temporal modulation for the gravitational field that exponentially decays when moving away from the source. The second regime, called the oscillatory regime, occurs when \(2\omega_s > m_{\phi} c\). It is only in this regime in which the source emits gravitational waves associated with the massive modes.

The solutions for \(\tilde{h}_+, \Psi_+\) and \(\tilde{h}_x, \Psi_x\) in the oscillatory regime are waves of the same amplitude, same frequency and different wave numbers, which provides an interpretation of interference effects. In this sense, it is convenient to introduce

\[ \Theta_{+,-} = \tilde{h}_{+,-} + \Psi_{+,-}. \]  

(48)

Equation (48) allows us to interpret the spin-2 waves as a single structure generated by interference between the fields \(\tilde{h}_{+,-}\) and \(\Psi_{+,-}\). Note that due to the difference in sign between \(\tilde{h}_{+,-}\) and \(\Psi_{+,-}\), what we have is a destructive interference effect. Furthermore, at the limit of \(m_{\phi} \to 0\), this destructive interference is complete, and in this case, the emission of tensorial modes does not occur. We will see in the next sections that physical interpretations of the binary system are consistent only when we treat massive and massless spin-2 modes together.

A. Gravitational energy-momentum tensor and the power radiated

The low-frequency effects of second-order terms contribute to background changes \([6]\). These terms, obtained from space-time averages \(<...>\), generate the gravitational energy-momentum tensor \(t_{\mu\alpha}\) given by

\[ t_{\mu\alpha} = -\frac{c^4}{8\pi G} \left[ \left< G_{\mu\alpha}^{(2)} \right> + \gamma \left< H_{\mu\alpha}^{(2)} \right> - 2\alpha \left< I_{\mu\alpha}^{(2)} \right> \right], \]  

(49)
where

\[ G_{\mu\nu}^{(2)} = R_{\mu\nu}^{(2)} - \frac{1}{2} \eta_{\mu\nu} R^{(2)} - \frac{1}{2} h_{\mu\nu} R^{(1)}, \]

\[ H_{\mu\nu}^{(2)} = R^{(1)} R_{\mu\nu}^{(1)} - \frac{1}{4} R^{(1)} R^{(1)} \eta_{\mu\nu} + h_{\mu\nu} \partial^\rho \partial_\rho R^{(1)} + \eta_{\mu\nu} \Box^{(1)} R^{(1)} + \eta_{\mu\nu} \partial^\rho \partial_\rho R^{(2)} - \nabla^{(1)} \partial_\alpha R^{(1)} - \partial_\mu \partial_\nu R^{(2)}, \]

\[ R_{\mu\nu}^{(2)} = (\nabla^\nu \nabla^\beta)^{(1)} C_{\mu\nu\alpha\beta}^{(1)} + \partial^\nu \partial^\beta C_{\mu\nu\alpha\beta}^{(2)} + \frac{1}{2} R^\rho^\beta (1) C_{\mu\nu\alpha\beta}^{(1)} . \]

After a long calculation presented in Appendix A, we get

\[ t_{\mu\alpha} = \frac{e^4}{8\pi G} \left[ \frac{1}{4} \left\langle \partial_\mu \tilde{h}_{\nu\beta} \partial_\alpha \tilde{h}^{\nu\beta} \right\rangle - \frac{1}{4} \left\langle \partial_\mu \Psi_{\nu\beta} \partial_\alpha \Psi^{\nu\beta} \right\rangle + \frac{3}{2} \left\langle \partial_\alpha \Phi \partial_\mu \Phi \right\rangle + \frac{1}{2} \left\langle \partial_\mu \tilde{h}_{\nu\beta} \partial_\alpha \Psi^{\nu\beta} \right\rangle \right] . \]

An important point to be discussed is the opposite (negative) sign that appears in the second term of Eq. (53) \[55\]. Although potentially pathological, this negative sign is expected because the Weyl-Weyl term presents Ostrogradsky instability, implying that the Hamiltonian density is not positive definite. However, in the context we are studying, it is possible to avoid any pathology by considering the massive and massless spin-2 modes as a single structure defined in Eq. (48). In this context, neglecting the scalar mode, we have two different situations:

- For \( 2\omega_s < m_\Phi c \) (damping regime), the massive spin-2 part does not emit radiation – \( \left\langle \partial_\mu \Psi_{\nu\beta} \partial_\alpha \Psi^{\nu\beta} \right\rangle = 0 \) – and the system behaves as in general relativity.

Furthermore, using analogous reasoning for \( \Psi_{+,x} \) and \( \Phi \), we obtain

\[ \partial_1 \Psi_+ = \begin{cases} \sqrt{\left( \frac{m_\Phi c}{2\omega_s} \right)^2 - 1 - \cot (2\omega_s t + 2\phi) \partial_0 \Psi_+}, & 2\omega_s < m_\Phi c \\ - \sqrt{1 - \left( \frac{m_\Phi c}{2\omega_s} \right)^2} \partial_0 \Psi_+, & 2\omega_s > m_\Phi c \end{cases}, \]

\[ \partial_1 \Psi_x = \begin{cases} \sqrt{\left( \frac{m_\Phi c}{2\omega_s} \right)^2 - 1 + \tan (2\omega_s t + 2\phi) \partial_0 \Psi_x}, & 2\omega_s < m_\Phi c \\ - \sqrt{1 - \left( \frac{m_\Phi c}{2\omega_s} \right)^2} \partial_0 \Psi_x, & 2\omega_s > m_\Phi c \end{cases}, \]

and

\[ \partial_1 \Phi = \begin{cases} \sqrt{\left( \frac{m_\Phi c}{2\omega_s} \right)^2 - 1 \cot (2\omega_s t + 2\phi) \partial_0 \Phi}, & 2\omega_s < m_\Phi c \\ - \sqrt{1 - \left( \frac{m_\Phi c}{2\omega_s} \right)^2} \partial_0 \Phi, & 2\omega_s > m_\Phi c \end{cases}. \]

\[ \text{For } 2\omega_s > m_\Phi c \text{ (oscillatory regime), spin-2 modes emit two waves that interfere destructively in such a way that the radiated energy is always less than the case of pure GR but always positive, i.e., } \left\langle \partial_\mu \tilde{h}_{\nu\beta} \partial_\alpha \tilde{h}^{\nu\beta} \right\rangle - \left\langle \partial_\mu \Psi_{\nu\beta} \partial_\alpha \Psi^{\nu\beta} \right\rangle > 0. \]

The radiated power per solid angle unit is given by

\[ \frac{dP}{d\Omega} = -c^2 l_{t01}. \]

Due to the functional form of \( \tilde{h}_{+,x} \) their radial derivatives \( \partial_1 \) can be switched to time derivatives \( \partial_0 \) up to \( \mathcal{O}(1/v^2) \):

\[ \partial_1 \tilde{h}_{+,x} = -\partial_0 \tilde{h}_{+,x}. \]

\[ \text{This phenomenon has been known for a long time in the context of quadratic gravity quantization} \[43\]. \]
Substituting these last results in Eq. [54] and calculating the spatial-time averages, we get [55]

\[
\frac{dP}{d\Omega} = -\frac{2G\mu^2 R^4 \omega_s^6}{\pi c^5} \left[ \left( \frac{1 + \cos^2 \theta}{2} \right)^2 + \cos^2 \theta \right] \left[ 1 - \Theta(2\omega_s - m_{\Psi}c) \sqrt{1 - \left( \frac{m_{\Psi}c}{2\omega_s} \right)^2} \right] (55)
\]

\[
+ \Theta(2\omega_s - m_{\Psi}c) \sqrt{1 - \left( \frac{m_{\Psi}c}{2\omega_s} \right)^2} \frac{1}{12} \sin^4 \theta \right] .
\]

The Heaviside functions \( \Theta(2\omega_s - m_{\Psi}c) \) and \( \Theta(2\omega_s - m_{\Psi}c) \) indicate that only the oscillatory regimes contribute to the radiated power. It is also worth noting that the cross term \( \left\langle \partial_\nu \tilde{h}_{\rho\beta} \partial_\theta \Psi^{\rho\beta} \right\rangle \) cancels out when averaged in time and space. One additional integration gives the expression for the total power radiated:

\[
P = -\frac{32}{5} \frac{c^5}{G} \left( \frac{GM_s \omega_s}{c^3} \right) \left[ 1 - \Theta(2\omega_s - m_{\Psi}c) \sqrt{1 - \left( \frac{m_{\Psi}c}{2\omega_s} \right)^2} + \frac{\Theta(2\omega_s - m_{\Psi}c)}{18} \sqrt{1 - \left( \frac{m_{\Psi}c}{2\omega_s} \right)^2} \right] .
\] (56)

Considering the tensorial part in the oscillatory regime and the scalar part in the damping regime, we get

\[
P_{spin} = -\frac{32}{5} \frac{c^5}{G} \left( \frac{GM_s \omega_s}{c^3} \right) \frac{10}{12} \left[ 1 - \sqrt{1 - \left( \frac{m_{\Psi}c}{2\omega_s} \right)^2} \right] .
\]

This last expression corroborates the previous statement that the emitted energy is always positive definite. In fact, for \( m_{\Psi}c = 2\omega_s \), we are at the threshold of the damping regime and the system loses energy exclusively by the massless spin-2 mode. As \( m_{\Psi} \) decreases, the destructive interference effect occurs between \( \tilde{h}_{+\times} \) and \( \Psi_{+\times} \) and the energy loss decreases monotonically. In the limiting case where \( m_{\Psi} \to 0 \), the destructive interference is maximum and the energy loss ceases to exist via tensorial modes. It is worth remembering that the limit \( m_{\Psi} \to 0 \Rightarrow a \to \infty \) is nonphysical since the term \( C_{\mu\nu\alpha\beta}C_{\mu\nu\alpha\beta} \) diverges in the action [1].

\[
\dot{\omega}_s = \frac{96}{5} \left( \frac{GM_s}{c^3} \right) \sqrt{\frac{11}{\omega_s}} \left[ 1 - \Theta(2\omega_s - m_{\Psi}c) \sqrt{1 - \left( \frac{m_{\Psi}c}{2\omega_s} \right)^2} + \frac{\Theta(2\omega_s - m_{\Psi}c)}{18} \sqrt{1 - \left( \frac{m_{\Psi}c}{2\omega_s} \right)^2} \right] .
\] (59)

The equation [59] determines the variation of the orbital frequency in the inspiral phase. The term within curly brackets contains the usual contribution from GR (first term) and additional contributions from the massive spin-2 and spin-0 modes. The massive modes only contribute when \( \Theta(2\omega_s - m_{\Psi}c) = 1 \) or \( \Theta(2\omega_s - m_{\Psi}c) = 1 \). That is, only when the solutions are in the oscillatory regime.

To analyze the effect of massive modes in the binary system, we will divide the study into two cases: in the first one, we only consider the tensorial mode in the oscillatory regime; in the second, we only take into account...
the scalar mode.

**GR plus massive spin-2 mode:** In this case we have \(2\omega_s > m_\Phi c\) and \(2\omega_s < m_\Phi c\), so that Eq. (59) contains only the first two terms. By integrating Eq. (59), we get the curves shown in Fig. 1.

![Figure 1](image1.png)

**FIG. 1.** Numerical solution of the balance equation in units of \(GM/c^3 = 1\), with initial condition \(\omega(0) = 0.5\) and taking into account only spin-2 modes. The red, blue and green curves are constructed with \(m_\Phi c = 1\), \(m_\Phi c = 0.9\) and \(m_\Phi c = 0.8\), respectively. The black curve represents the pure GR solution.

Figure 1 presents solutions for the combined spin-2 structure, i.e., \(\Theta_{\mu\nu} = \tilde{h}_{\mu\nu} + \Psi_{\mu\nu}\), and the pure case of general relativity. This figure clearly shows that the coalescence time increases as the value \(m_\Phi c\) decreases. It occurs because the reduction of \(m_\Phi c\) makes the process of destructive interference between the \(\tilde{h}_{\mu\nu}\) and \(\Psi_{\mu\nu}\) modes more effective, and consequently, the binary system loses energy more slowly. It is important to note that for \(m_\Phi c > 0\), i.e. \(\alpha\) finite, coalescence always occurs.

**GR plus massive spin-0 mode:** In this other configuration we have \(2\omega_s < m_\Phi c\) and \(2\omega_s > m_\Phi c\), and therefore only the first and third terms are present in equation (59). By integrating Eq. (59) in this context, we get the results shown in Fig. 2.

![Figure 2](image2.png)

**FIG. 2.** Numerical solution of the balance equation in units of \(GM/c^3 = 1\), with initial condition \(\omega(0) = 0.5\) and taking into account only the spin-0 and massless spin-2 modes. The red and blue curves are constructed with \(m_\Phi c = 1\) and \(m_\Phi c = 0.1\), respectively. The black curve represents the pure general relativity solution.

Figure 2 presents solutions for the combined spin-2 structure, i.e. \(\Theta_{\mu\nu} = \tilde{h}_{\mu\nu} + \Psi_{\mu\nu}\), and the pure case of general relativity. This figure clearly shows that the coalescence time increases as the value \(m_\Phi c\) decreases. It occurs because the reduction of \(m_\Phi c\) makes the process of destructive interference between the \(\tilde{h}_{\mu\nu}\) and \(\Psi_{\mu\nu}\) modes more effective, and consequently, the binary system loses energy more slowly. It is important to note that for \(m_\Phi c > 0\), i.e. \(\alpha\) finite, coalescence always occurs.

The combination of massive and massless modes at detection time \(t_d\) occurs with waves that were emitted at different times and therefore have different frequencies. If the \(\tilde{h}_{+,\times}\) mode was emitted in \(t_e\), the \(\Psi_{+,\times}\) mode was necessarily emitted earlier in \(t_{\epsilon_m}\). In this case, the frequency \(\omega_s(t_e)\) associated with the massless mode is greater than the frequency \(\omega_s(t_{\epsilon_m})\) associated with the massive mode.

![Diagram](image3.png)

**VI. SPIN-2 WAVEFORM**

Once the orbital dynamics of the binary system is established, we will study what is the waveform of the unique spin-2 structure detected at a certain point in space. \(^{10}\) We saw earlier that the complete spin-2 wave is composed of two modes, namely \(\tilde{h}_{+,\times}\) and \(\Psi_{+,\times}\), which interfere destructively. At the time of emission, these two modes have the same frequency and amplitude, but this is no longer true at the time of detection. The main point of this analysis is that the massive and massless modes propagate at different velocities. While the \(\tilde{h}_{+,\times}\) mode propagates with velocity \(c\), the \(\Psi_{+,\times}\) mode propagates with group velocity

\[
v_g(t) = \frac{d\omega}{dk}
\]

where \(\omega = c\sqrt{k^2 + m_\Phi^2}\) is the dispersion relation of the massive mode. Remembering that in the approximation of quasicircular orbits we have \(\omega = 2\omega_s\), we can write the velocity \(v_g\) as

\[
v_g = \sqrt{1 - \left(\frac{m_\Phi c}{2\omega_s}\right)^2}, \tag{60}
\]

with \(v_g < c\). The difference in propagation velocities between the two modes generates the phenomenon of dispersion in the complete spin-2 wave.

The combination of massive and massless modes at detection time \(t_d\) occurs with waves that were emitted at different times and therefore have different frequencies. If the \(\tilde{h}_{+,\times}\) mode was emitted in \(t_e\), the \(\Psi_{+,\times}\) mode was necessarily emitted earlier in \(t_{\epsilon_m}\). In this case, the frequency \(\omega_s(t_e)\) associated with the massless mode is greater than the frequency \(\omega_s(t_{\epsilon_m})\) associated with the massive mode.

\(^{10}\) During this section, we assume that there is no scalar mode emission.
Based on the previous discussion, we can write the relationships between the detection time and the emission times as

\[ t_e = t_d - \frac{r}{c}, \quad (61) \]

\[ t_{e_m} = t_d - \frac{r}{v_g(t_{e_m})}. \quad (62) \]

Combining these two expressions and using Eq. (60), we get

\[ t_{e_m} = t_e + \frac{r}{c} \left( 1 - \frac{1}{\sqrt{1 - \left( \frac{m \phi c}{\omega_s(t_{e_m})} \right)^2}} \right). \quad (63) \]

The previous equation is an algebraic equation for \( t_{e_m} \) which together with Eq. (59) allows us to determine \( t_{e_m} \) and \( \omega_s(t_{e_m}) \).

In order to exemplify the phenomenon of dispersion in the spin-2 complete wave, we consider a hypothetical binary system of \( M_e = 10M_\odot \) located at a distance of 10 Kpc. We also assume \( m \phi c = 0.02 \text{ s}^{-1} \) and neglect the scalar mode emission.\(^{11}\) For convenience \( t_e \) is adopted as a time evolution variable and we consider \( \omega_s(t_e = 0) = 0.01 \text{ Hz} \). This initial condition causes the \( \Psi_{+,\times} \) mode to transition from the damping regime to the oscillatory one exactly at \( t_e = 0 \).

The next step is to numerically solve the balance equation (59) obtaining \( \omega_s(t) \), and then determine \( t_{e_m} \) by Eq. (63) considering different values of \( t_e \). To facilitate this analysis, we define the functions

\[ f(t_{e_m}) = t_{e_m} \]

and

\[ g(t_{e_m}) = t_e + \frac{r}{c} \left( 1 - \frac{1}{\sqrt{1 - \left( \frac{m \phi c}{\omega_s(t_{e_m})} \right)^2}} \right). \]

Figure 3 shows plots of the functions \( f(t_{e_m}) \) and \( g(t_{e_m}) \) for three distinct values of \( t_e \).

\[ \text{FIG. 3. Plots of the functions } f(t_{e_m}) \text{ (black) and } g(t_{e_m}) \text{ (red) considering three values of } t_e. \]

The plots sequence in Fig. 3 shows that as \( t_e \) increases, the red curve shifts upwards. Furthermore, from \( t_e = 37.7 \text{ Kyr} \), this curve intercepts the black curve indicating the existence of solutions of Eq. (63). Physically this means that the first wave fronts of the massive modes take 37.7 Kyr to travel a distance of 10 Kpc. Furthermore, due to the nonlinearity of velocity \( v_g(t) \), we see that the complete spin-2 wave detected is composed by the superposition of a massless mode \( \tilde{h}_{+,\times} \) and two massive modes \( \Psi_{+,\times}^{(1,2)} \). This fact is evidenced by the double solution of Eq. (63), which occurs from \( t_e = 37.7 \text{ Kyr} \).

Figure 4 shows waveforms \( \Theta_+ = \tilde{h}_{+} (\omega_s^0) + \Psi_{+}^{(1)} (\omega_{s_{m(1)}}^0) + \Psi_{+}^{(2)} (\omega_{s_{m(2)}}^0) \) considering the same three values of \( t_e \) presented above.

The plots in Fig. 4 show the full tensorial mode waveforms associated with polarization plus. In the interval \( 0 \leq t_e < 37.7 \text{ Kyr} \) only the massless mode is present, and \( \Theta_+ \) has the form of a pure sinusoid. From \( t_e \geq 37.7 \text{ Kyr} \), the three modes \( \tilde{h}_{+}, \Psi_{+}^{(1)} \) and \( \Psi_{+}^{(2)} \) combine and generate an interference pattern. For \( t_e \approx 37.7 \text{ Kyr} \) (second plot of figure 4), the two massive modes have similar frequencies and contribute similarly to the structure of \( \Theta_+ \). As \( t_e \) increases, the \( \Psi_{+}^{(2)} \) mode (lower frequency mode) decreases in importance compared to \( \Psi_{+}^{(1)} \). In the last plot of figure 4 we present a moment when the complete wave-

\(^{11}\) This can be obtained by considering \( m \phi c \) much higher than the typical orbital frequency of the binary system.
with some deformity generated by the presence of $\Psi_{\pm}^{(2)}$. In the next section, we will use the nonexistence of an interference pattern in gravitational wave observations to constrain the parameter $m_{\Psi}$.

A. Observational constraints

The waveform detected in the inspiral phase of a binary black hole system allows constraining the parameter $m_{\Psi}$. It is possible because the presence of massive modes produces an interference pattern (plots in Fig. 4) that is clearly not observed. To obtain these constraints, we will consider the event GW170104, which consists of the merge of two black holes with a Chirp mass $M_c = 21.1 M_\odot$ and a distance of $r = 880 \text{ Mpc}$. Figure 1 of Ref. [58] indicates that the gravitational wave is detected initially at $t_{\text{ini}} = 0.5 \text{ s}$ with frequency $f_{GW} \approx 45 \text{ Hz}$, and the merge occurs around $t_{\text{mer}} = 0.59 \text{ s}$.

The estimated constraint for $m_{\Psi}$ is performed as follows:

- Using the initial condition $\omega_s(t_{\text{ini}}) = \pi f_{GW} = 141 \text{ Hz}$, we numerically solve the balance equation [59] for different values of $m_{\Psi}$. It is done considering that the spin-0 mode is in the damping regime.
- Knowing $\omega_s(t)$ and using $t_c = t_{\text{ini}}$, we determine the largest value of $m_{\Psi}$ in which Eq. (63) has a solution for $t_{\text{mer}}$. Numerically this corresponds to a configuration equivalent to the second plot in Fig. 3.

The procedure above establishes the maximum value of $m_{\Psi}$ at which the massive mode produces an interference pattern of the type shown in Fig. 4. As this pattern is not observed in event GW170104, the maximum value obtained establishes a lower bound for $m_{\Psi}$. Table I shows the result of this constraint:

| Spin-2 | $\omega_{s}^{c_m}$ | $\omega_{s}^{c_m(2)}$ | $m_{\Psi}$ (\%) | $\alpha$ (\%) |
|--------|-----------------|-----------------|----------------|--------------|
|        | 141 Hz          | 77 Hz           | $4.2 \times 10^{-11}$ m$^{-1}$ | $1.1 \times 10^{12}$ m$^2$ |

**TABLE I.** Emission frequencies of the massive ($\omega_{s}^{c_m}$) and massless ($\omega_{s}^{c_m}$) tensorial modes, and constraints for the parameters $m_{\Psi}$ and $\alpha$ where $m_{\Psi}^2 = 2/\alpha$. Note that the two massive modes have approximately the same frequency given by $\omega_{s}^{c_m}$. Furthermore, since $\omega_{s}^{c_m}$ and $\omega_{s}^{c_m}$ differ only by a factor of 2, the amplitudes of the modes $\Psi_{\pm}^{(1,2)}$ and $\tilde{h}_{\pm, \times}$ are similar. Thus, for $m_{\Psi} < 4.2 \times 10^{-11}$ m$^{-1}$, we obtain an interference pattern similar to the one shown in the second plot of figure 4.

Another way to obtain a more restrictive constraint for $m_{\Psi}$ is through the coalescence time $\Delta_{\text{col}}$. From Fig. 1, we see that the coalescence time increases substantially

\[12\] We only take into account the best-fit parameters.
as $m_\Psi c$ decreases. On the other hand, event GW170104 observes a coalescence time $\Delta_{\text{col}}^{ob} \sim 0.1 \text{ s}$ counted from the initial setting $\omega_s(t_{\text{ini}}) = 141 \text{ Hz}$. Thus, imposing that the presence of the massive mode cannot change (in order of magnitude) the observed value of $\Delta_{\text{col}}^{ob}$, we can constrain the parameters $m_\Psi$ and $\alpha$.

The coalescence time is calculated from Eq. (59) and essentially depends on the parameters $M_e$ and $m_\Psi$. Solutions to this equation show that as $M_e$ and $m_\Psi$ increase $\Delta_{\text{col}}$ decreases. In principle, any decrease in $m_\Psi$ can be offset by an increase in $M_e$ leaving $\Delta_{\text{col}}$ invariant. However, there is strong theoretical\cite{69} and observational\cite{60, 61} evidence that the mass of Chirp is "always" less than $100M_\odot$.\cite{14} Thus, assuming the maximum value $M_e = 100M_\odot$, we can establish a lower bound for $m_\Psi$ requiring $\Delta_{\text{col}}$ to be compatible with the observed value $\Delta_{\text{col}}^{ob}$.

In Fig. 5, we show the solution $\omega_s(t)$ for different values of the parameter $m_\Psi$ with $M_e = 100M_\odot$:

![Plot of the function $\omega_s(t)$](image)

**FIG. 5.** Plot of the function $\omega_s(t)$ considering the initial condition $\omega_s(0.5) = 141 \text{ Hz}$ and $M_e = 100M_\odot$. The blue, red and black curves are constructed with $m_\Psi c = 120 \text{ s}^{-1}$, $m_\Psi c = 86 \text{ s}^{-1}$ and $m_\Psi c = 70 \text{ s}^{-1}$, respectively. The vertical dashed curve indicates $\Delta_{\text{col}} = 1 \text{ s}$.

The coalescence time is calculated from $\Delta_{\text{col}} = t_{\text{col}} - 0.5$, where $t_{\text{col}}$ is the instant when the functions in Fig. 5 diverge. Thus, for the models described by the blue, red and black curves, we obtain $\Delta_{\text{col}} = 0.5 \text{ s}$, $1 \text{ s}$ and $1.5 \text{ s}$, respectively. Furthermore, these values correspond to the minimum coalescence times of a given model $m_\Psi$ as they were calculated with the maximum value $M_e = 100M_\odot$. If we decrease the chirp mass with $m_\Psi$ fixed, we get a larger value for $\Delta_{\text{col}}$.

Based on the previous discussion, we can estimate a lower bound for the parameter $m_\Psi$ considering $\Delta_{\text{col}} \leq \Delta_{\text{col}}^{ob}$. In principle, we should use $\Delta_{\text{col}}^{ob} \sim 0.1 \text{ s}$. However, to compensate for the errors generated by the approximations performed (nonrelativistic dynamics, point masses, etc.), we reduce the constraint by 1 order of magnitude and consider $\Delta_{\text{col}} \leq 1 \text{ s}$\cite{15}. Thus, from Fig. 5 we see that $m_\Psi c$ must be larger than $86 \text{ s}^{-1}$, which results in the following constraint shown in Table III.

| Spin-2 | $m_\Psi (\odot)$ | $\alpha (\odot)$ |
|--------|-----------------|-----------------|
| 3 $\times$ 10^{-2} | 10^{-2} $\text{ m}^2$ | 2 $\times$ 10^{-2} $\text{ m}^2$ |

**TABLE II.** Constraints to parameters $m_\Psi$ and $\alpha$ taking into account $\Delta_{\text{col}} \leq 1 \text{ s}$.

Due to the various approximations performed, the estimates presented in Table III must be considered only in order of magnitude. Still, the constraint for the $\alpha$ parameter via coalescence time is about 8 orders of magnitude more restrictive than the constraint obtained via the interference pattern.

### VII. FINAL COMMENTS

In this paper, we studied GWs emitted by binary point-mass black hole systems in the context of the quadratic gravity model assuming nonrelativistic and circular orbit approximations. The GWs solutions were calculated by taking into account the dominant terms in the multipolar expansion. They exhibit three modes: a massive spin-2 mode $\Psi_{\mu\nu}$, a massive spin-0 mode $\Phi$, and the expected massless spin-2 mode $h_{\mu\nu}$. Besides, the massive modes present two different behaviors: the oscillatory regime, which plays the real role of GW; and the damped regime, which presents an exponential decay.

We calculated the energy-momentum tensor $t_{\mu\nu}$ of the GWs and showed that it presents the Ostrogradsky instability. To circumvent this potential problem and obtain a consistent physical interpretation\cite{63}, we consider spin-2 waves as a single structure given as a result of the destructive interferences between the fields $h_{\mu\nu}$ and $\Psi_{\mu\nu}$. Having obtained the $t_{\mu\nu}$, we constructed the energy balance equation and studied how the quadratic gravity model modifies the orbital dynamics of point-mass black hole binaries. We showed that the spin-2 structure takes a longer time to reach coalescence indicating the system loses energy more slowly when compared to GR. For the case of spin-0 plus GR, we have a shorter time to reach coalescence indicating that the system loses energy faster than the GR pure case.

---

13 Again, we consider that the spin-0 mode is in the damping regime.

14 By “always” we mean that the existence of a binary black hole system with $M_e \gtrsim 100M_\odot$ is highly improbable.

15 Relativistic corrections are essential to correctly describe the orbital dynamics close to the merger. However, they do not change the coalescence time in order of magnitude. For example, the predicted coalescence time for event GW1701104 in GR on the quadrupole approximation is $\Delta_{\text{col}} = 0.16 \text{ s}$. 
We determined the waveform that a detector would observe for the complete spin-2 structure. When the massive mode is not present, we obtain a pure sine wave. However, when it is present, we get a clear interference pattern. Using the nonobservation of this interference pattern, we constrain the parameter to \( m_\Phi \gtrsim 4.2 \times 10^{-11} \text{m}^{-1} \) or \( \alpha \lesssim 1.1 \times 10^{21} \text{m}^2 \). Furthermore, based on the coalescence time, we developed a second method to constrain \( m_\Phi \). By this method, we obtain \( m_\Phi \gtrsim 3 \times 10^{-7} \text{m}^{-1} \) or \( \alpha \lesssim 2 \times 10^{13} \text{m}^2 \), which is 8 orders of magnitude more restrictive than the previous one.

The methods presented in Sec. VI A do not effectively constrain the parameter \( m_\Phi \) or \( \gamma \). The main reason for this is the structural difference between the solutions \( \Phi \) and \( \Psi_{+,-} \). For example, the scalar mode presents a longitudinal polarization differently from the tensor modes \([3, 45]\). This difference leads to factor 1/18 which appears in the balance equation and makes the energy loss via scalar mode ineffective.

There are some papers in the literature that constrain the parameters of quadratic gravity. On astrophysical scales, of the order of stellar systems, we get restrictions on the parameters of quadratic gravity. On astrophysical scales, the Eötvös torsion balance experiment \([67]\) provides bounds for both \( \gamma \) and \( \alpha \) parameters. Based on the static weak-field solution of quadratic gravity \([47]\), the Eötvös experiment constrains \( \alpha \sim \gamma \lesssim 2 \times 10^{-9} \text{m}^2 \). Even though earthly bounds are much more restrictive than astrophysical ones, it is always important to test alternative models of gravity at different scales.

The circular orbit approximation motivates future work in which noncircular orbits are considered from the beginning. In this context, it would be possible to study the loss of angular momentum and the effects of orbit circularization. This would be particularly interesting in quadratic gravity, where the presence of the Weyl-Weyl term generates the Ostrogradsky instability.

**Appendix A: The gravitational energy-momentum tensor**

In this Appendix, we calculate the gravitational energy-momentum tensor

\[
t_{\mu\alpha} = -\frac{c^4}{8\pi G} \left[ G^{(2)}_{\mu\alpha} + \gamma H^{(2)}_{\mu\alpha} - 2\alpha I^{(2)}_{\mu\alpha} \right]
\]

where \( G^{(2)}_{\mu\alpha} \), \( H^{(2)}_{\mu\alpha} \) and \( I^{(2)}_{\mu\alpha} \) are given in Eqs. (50), (51), and (52), respectively.

The brackets \( \langle \ldots \rangle \) represent space-time averages of wave-like solutions obtained from Eqs. (14), (18), and (9). These averages are taken considering several periods of time and space in such a way that in these averages we can perform integrations by parts and neglect the surface terms \([33]\). Using this property, we will simplify \( \langle H^{(2)}_{\mu\alpha} \rangle \) and \( \langle I^{(2)}_{\mu\alpha} \rangle \). So, remembering that

\[
\nabla_\rho \partial_\alpha R = \partial_\nu \partial_\alpha R - \Gamma^\nu_{\mu\alpha} \partial_\rho R,
\]

we have for \( \langle H^{(2)}_{\mu\alpha} \rangle \)

\[
\langle H^{(2)}_{\mu\alpha} \rangle = \langle R^{(1)}_{\mu\alpha} R^{(1)} \rangle - \frac{1}{4} \eta_{\mu\alpha} \langle R^{(1)} R^{(1)} \rangle + \langle h_{\mu\alpha} \nabla_\alpha R^{(1)} \rangle + \langle h_{\mu\alpha} \beta R^{(1)} \rangle + \langle \Gamma^{\rho(1)}_{\mu\alpha} \partial_\rho R^{(1)} \rangle
\]

\[
= \langle R^{(1)}_{\mu\alpha} R^{(1)} \rangle - \frac{1}{4} \eta_{\mu\alpha} \langle R^{(1)} R^{(1)} \rangle + \langle h_{\mu\alpha} \nabla_\alpha R^{(1)} \rangle - \eta_{\mu\alpha} \langle h^{\lambda\kappa} \partial_\kappa \partial_\lambda R^{(1)} \rangle - \eta_{\mu\alpha} \langle \Gamma^{\rho(1)}_{\mu\kappa} \partial_\kappa R^{(1)} \rangle
\]

\[
+ \langle \Gamma^{\rho(1)}_{\mu\alpha} \partial_\rho R^{(1)} \rangle.
\]
where $\Box = \partial^\rho \partial_\rho$. To obtain $\langle I_{\mu \alpha}^{(2)} \rangle$, we must develop the term
\begin{align*}
\langle (\nabla^\nu \nabla^\beta)^{(1)} C_{\mu \nu \alpha \beta}^{(1)} \rangle &= \langle (g^\nu_\rho \partial_\rho \nabla^\beta)^{(1)} C_{\mu \nu \alpha \beta}^{(1)} \rangle - \langle (g^\nu_\rho \Gamma^\rho_\kappa_\mu \nabla^\beta)^{(1)} C_{\mu \nu \alpha \beta}^{(1)} \rangle - \langle (g^\nu_\rho \Gamma^\rho_\kappa_\nu \nabla^\beta)^{(1)} C_{\mu \nu \alpha \beta}^{(1)} \rangle \\
&- \langle (g^\nu_\rho \Gamma^\rho_\kappa_\nu \nabla^\beta)^{(1)} C_{\mu \nu \alpha \beta}^{(1)} \rangle
\end{align*}

with these simplifications, the first-order quantities obtained in Sec. II simplify to
\begin{align*}
\langle h_{\mu \alpha}^{(1)} \rangle &= -\langle h_{\mu \alpha} \rangle + \partial_\mu \partial_\alpha \Phi - \eta_{\mu \alpha} \Phi_1^{(1)} + \frac{1}{2} \eta_\mu \eta_\alpha \langle R_{\mu \alpha}^{(2)} \rangle.
\end{align*}

Therefore,
\begin{align*}
\langle G_{\mu \alpha}^{(2)} \rangle &= \langle R_{\mu \alpha}^{(2)} \rangle - \frac{1}{2} \eta_{\mu \alpha} \langle R^{(2)} \rangle - \frac{1}{2} \langle h_{\mu \alpha} R^{(1)} \rangle, \\
\langle H_{\mu \alpha}^{(2)} \rangle &= \langle R_{\mu \alpha}^{(1)} \rangle - \frac{1}{4} \eta_{\mu \alpha} \langle R^{(1)} \rangle + \langle h_{\mu \alpha} \Box R^{(1)} \rangle - \eta_{\mu \alpha} \langle h_{\nu \alpha} \partial_\nu \partial_\lambda R^{(1)} \rangle - \eta_{\mu \alpha} \eta_{\nu \alpha} \langle \Gamma_{\nu \alpha}^{(1)} \partial_\mu R^{(1)} \rangle \\
&+ \langle \Gamma_{\mu \alpha}^{(1)} \partial_\mu R^{(1)} \rangle, \\
\langle I_{\mu \alpha}^{(2)} \rangle &= -\langle h_{\nu \alpha} \partial_\nu \partial_\alpha \Phi \rangle - \eta_{\nu \alpha} \langle \Gamma_{\mu \alpha}^{(1)} \partial_\mu \partial_\nu \Phi \rangle - \eta_{\nu \alpha} \langle \Gamma_{\mu \alpha}^{(1)} \partial_\mu \partial_\nu \Phi \rangle - \eta_{\nu \alpha} \langle \Gamma_{\mu \alpha}^{(1)} \partial_\mu \partial_\nu \Phi \rangle + \frac{1}{2} \eta_\nu \eta_\alpha \langle R_{\mu \alpha}^{(1)} \rangle.
\end{align*}

The next step is to calculate the various terms needed using decomposition (20). As $t_{\mu \nu}$ is calculated in vacuum, we can use the traceless-transverse gauge, and in this case, $\tilde{h} = \Psi = 0$ e $\Box h_{\mu \alpha} = 0$. Then, the decomposed metric is rewritten as
\begin{align*}
\tilde{h}_{\mu \alpha} &= \tilde{h}_{\mu \alpha} + \Psi_{\mu \alpha} - \eta_{\mu \alpha} \Phi.
\end{align*}

With these simplifications, the first-order quantities obtained in Sec. III simplify to
\begin{align*}
R^{(1)} &\approx -3 \Box \Phi, \\
R_{\mu \alpha}^{(1)} &\approx -\frac{1}{2} \Box \Psi_{\mu \alpha} - \partial_\mu \partial_\alpha \Phi + \eta_{\mu \alpha} \Box \Phi - \eta_{\mu \alpha} \Phi_1^{(1)}.
\end{align*}

\begin{align*}
C_{\mu \nu \alpha \beta}^{(1)} &= \frac{1}{2} \left[ \partial_\alpha \partial_\nu \left( \tilde{h}_{\mu \beta} + \Psi_{\mu \beta} \right) - \partial_\beta \partial_\nu \left( \tilde{h}_{\mu \alpha} + \Psi_{\mu \alpha} \right) + \partial_\beta \partial_\mu \left( \tilde{h}_{\nu \alpha} + \Psi_{\nu \alpha} \right) - \partial_\alpha \partial_\mu \left( \tilde{h}_{\nu \beta} + \Psi_{\nu \beta} \right) \right] \\
&+ \frac{1}{4} \left[ \eta_{\mu \alpha} \Box \Psi_{\beta \mu} - \eta_{\mu \beta} \Box \Psi_{\nu \alpha} + \eta_{\nu \beta} \Box \Psi_{\mu \alpha} - \eta_{\nu \alpha} \Box \Psi_{\mu \beta} \right],
\end{align*}

\begin{align*}
\partial_\beta C_{\mu \nu \alpha \beta}^{(1)} &= \frac{1}{4} \left[ \partial_\mu \Box \Psi_{\nu \alpha} - \partial_\alpha \Box \Psi_{\nu \mu} \right],
\end{align*}

and
\begin{align*}
\Gamma_{\mu \alpha}^{(1)} &= \frac{1}{2} \eta_\nu \eta_\lambda \left( \partial_\alpha h_{\lambda \mu} + \partial_\mu h_{\lambda \alpha} - \partial_\lambda h_{\alpha \mu} \right).
\end{align*}

The term $\langle G_{\mu \alpha}^{(2)} \rangle$ is given by the Eq. (A2). The calculation of the terms $\langle R_{\mu \alpha}^{(2)} \rangle$ and $\langle R^{(2)} \rangle$ are extensive but straightforward and results in
\begin{align*}
\langle R_{\mu \alpha}^{(2)} \rangle &= -\frac{1}{4} \langle \partial_\mu \tilde{h}_{\nu \alpha} \partial_\alpha \tilde{h}_{\nu \beta} \rangle - \frac{1}{4} \langle \partial_\mu \Psi_{\nu \beta} \partial_\alpha \Psi_{\nu \beta} \rangle + \frac{1}{2} \langle \partial_\alpha \Phi \partial_\mu \Phi \rangle - \frac{1}{2} \langle \partial_\mu \tilde{h}_{\nu \alpha} \partial_\alpha \Psi_{\nu \beta} \rangle + \frac{1}{2} \langle \partial_\Lambda \Psi_{\nu} \partial_\Lambda \Psi_{\nu} \rangle
\end{align*}
and
\[ \left\langle R^{(2)} \right\rangle = -\frac{9}{2} \left( \partial^{\nu} \Phi \partial_{\nu} \Phi \right) - \frac{1}{4} \left( \partial_{\nu} \Psi^{\nu} \partial_{\nu} \Psi \right). \] (A12)

Substituting the results \([A11], [A12], [A6], \) and \([A5]\) in \( \left\langle G^{(2)}_{\mu \alpha} \right\rangle \), we get
\[ \left\langle G^{(2)}_{\mu \alpha} \right\rangle = -\frac{1}{4} \left( \partial_{\mu} \hat{h}_{\nu \beta} \partial_{\alpha} \hat{h}_{\nu \beta} \right) - \frac{1}{4} \left( \partial_{\mu} \Psi_{\nu \beta} \partial_{\alpha} \Psi_{\nu \beta} \right) - \frac{1}{2} \left( \partial_{\mu} \hat{h}_{\nu \beta} \partial_{\alpha} \Psi_{\nu \beta} \right) + \frac{1}{2} \left( \partial_{\alpha} \Phi \partial_{\mu} \Phi \right) \]
\[ - \frac{1}{2} \left( \Psi_{\mu \alpha} \partial_{\nu \beta} \Psi_{\nu \beta} \right) - \frac{1}{4} \eta_{\mu \alpha} \left( \Phi \square \Phi \right) - \frac{1}{8} \eta_{\mu \alpha} \left( \Psi_{\nu \beta} \partial_{\nu \beta} \Psi_{\nu \beta} \right) + \frac{3}{2} \left( \Psi_{\mu \alpha} \square \Phi \right). \] (A13)

The field equations \([18]\) and \([9]\) in vacuum can be written as
\[ \square \Psi_{\mu \alpha} = \frac{1}{\alpha} \Psi_{\mu \alpha} \quad \text{and} \quad \square \Phi = \frac{1}{3 \gamma} \Phi. \] (A14)

Substituting these equations into \( \left\langle G^{(2)}_{\mu \alpha} \right\rangle \), we get
\[ \left\langle G^{(2)}_{\mu \alpha} \right\rangle = -\frac{1}{4} \left( \partial_{\mu} \hat{h}_{\nu \beta} \partial_{\alpha} \hat{h}_{\nu \beta} \right) - \frac{1}{4} \left( \partial_{\mu} \Psi_{\nu \beta} \partial_{\alpha} \Psi_{\nu \beta} \right) - \frac{1}{2} \left( \partial_{\mu} \hat{h}_{\nu \beta} \partial_{\alpha} \Psi_{\nu \beta} \right) + \frac{1}{2} \left( \partial_{\alpha} \Phi \partial_{\mu} \Phi \right) \]
\[ - \frac{1}{2 \alpha} \left( \Psi_{\mu \alpha} \Psi_{\nu \beta} \right) - \frac{1}{12 \gamma} \eta_{\mu \alpha} \left( \Phi \right)^{2} - \frac{1}{8 \alpha} \eta_{\mu \alpha} \left( \Psi_{\nu \beta} \Psi_{\nu \beta} \right), \] (A15)

where we use that \( \left\langle \Psi_{\mu \alpha} \Phi \right\rangle = 0 \). The relation \( \left\langle \Psi_{\mu \alpha} \Phi \right\rangle = 0 \) is derived from the vacuum field equations from the following construction:
\[ \Phi \square \Psi_{\mu \alpha} = \frac{1}{\alpha} \Phi \Psi_{\mu \alpha} \quad \text{and} \quad \Psi_{\mu \alpha} \square \Phi = \frac{1}{3 \gamma} \Phi \Psi_{\mu \alpha} \Rightarrow \]
\[ \left( \Phi \square \Psi_{\mu \alpha} - \Psi_{\mu \alpha} \square \Phi \right) = \left( \frac{1}{\alpha} - \frac{1}{3 \gamma} \right) \left( \Phi \Psi_{\mu \alpha} \right) \Rightarrow \]
\[ \frac{1}{3 \gamma} \left( 3 \gamma - \alpha \right) \left( \Phi \Psi_{\mu \alpha} \right) = 0. \]

Thus, for \( \alpha \neq 3 \gamma \), we have \( \left\langle \Phi \Psi_{\mu \alpha} \right\rangle = 0 \). The quantity \( \left\langle H^{(2)}_{\mu \alpha} \right\rangle \) is given by the Eq. \([A3]\). Calculating each of the terms present in \( \left\langle H^{(2)}_{\mu \alpha} \right\rangle \), we obtain

- **First term:**
\[ \left\langle R^{(1)} R^{(1)}_{\mu \alpha} \right\rangle = \frac{3}{2} \left( \square \Phi \right) \Psi_{\mu \alpha} + 3 \left( \square \Phi \partial_{\mu} \partial_{\alpha} \Phi \right) - 3 \eta_{\mu \alpha} \left( \left( \square \Phi \right)^{2} \right) + \eta_{\mu \alpha} \frac{3}{2 \gamma} \left( \Phi \square \Phi \right). \] (A16)

- **Second term:**
\[ \left\langle R^{(1)} R^{(1)} \right\rangle = 9 \left( \left( \square \Phi \right)^{2} \right). \] (A17)

- **Third term:**
\[ \left\langle h_{\mu \alpha} \square R^{(1)} \right\rangle = -3 \left( \square \Psi_{\alpha \mu} \square \Phi \right) - 3 \eta_{\alpha \mu} \left( \left( \square \Phi \right)^{2} \right). \] (A18)

- **Fourth term:**
\[ \left\langle h^{\lambda \kappa} \partial_{\lambda} \partial_{\kappa} R^{(1)} \right\rangle = -3 \left( \left( \square \Phi \right)^{2} \right). \] (A19)

- **Fifth term:**
\[ \eta^{\lambda \kappa} \left( \Gamma^{(1)}_{\kappa \lambda} \partial_{\mu} R^{(1)} \right) = -3 \left( \left( \square \Phi \right)^{2} \right). \] (A20)
• Sixth term:

\[ \langle \Gamma^{(1)}_{\mu\alpha} \partial_{\mu} R^{(1)} \rangle = 3 \langle \partial_{\mu} \partial_{\alpha} \Phi \square \Phi \rangle - \frac{3}{2} \langle \square \Psi_{\alpha\mu} \square \Phi \rangle - \frac{3}{2} \eta_{\alpha\mu} \langle (\square \Phi)^2 \rangle. \]  

(A21)

Then we substitute these six results in the expression of \( \langle H^{(2)}_{\mu\alpha} \rangle \) obtaining

\[ \langle H^{(2)}_{\mu\alpha} \rangle = 6 \langle \square \Phi \partial_{\mu} \partial_{\alpha} \Phi \rangle - \frac{15}{4} \eta_{\mu\alpha} \langle (\square \Phi)^2 \rangle + \eta_{\mu\alpha} \frac{3}{2\gamma} \langle \Phi \square \Phi \rangle - 3 \langle \square \Psi_{\alpha\mu} \square \Phi \rangle. \]  

(A22)

Analogously to the case of \( \langle G^{(2)}_{\mu\alpha} \rangle \), we can use the field equations \( \text{(A14)} \) and rewrite \( \langle H^{(2)}_{\mu\alpha} \rangle \) as

\[ \langle H^{(2)}_{\mu\alpha} \rangle = \frac{1}{\gamma} \left( \frac{1}{12\gamma} \eta_{\mu\alpha} \langle \Phi^2 \rangle - 2 \langle \partial_{\mu} \Phi \partial_{\alpha} \Phi \rangle \right), \]  

(A23)

where we use again that \( \langle \Psi_{\alpha\mu} \Phi \rangle = 0 \).

The quantity \( \langle J^{(2)}_{\mu\alpha} \rangle \) is given by the Eq. \( \text{(A4)} \). Calculating each of the terms present in \( \langle J^{(2)}_{\mu\alpha} \rangle \), we obtain:

• First term:

\[ \langle h^{\nu\kappa} \partial_{\kappa} \partial^{\beta} C^{(1)}_{\mu\nu\alpha\beta} \rangle = -\frac{1}{4} \langle \square \Phi \square \Phi_{\mu\alpha} \rangle. \]  

(A24)

• Second term:

\[ \eta^{\nu\kappa} \langle \Gamma^{(1)}_{\kappa\mu} \partial^{\beta} \mu_{\nu\alpha\beta} \rangle = \frac{1}{4} \langle \square \Psi_{\alpha} \square \Psi_{\mu} \rangle + \frac{1}{4} \langle \square \Psi_{\mu} \square \Phi \rangle. \]  

(A25)

• Third term:

\[ \eta^{\nu\kappa} \langle \Gamma^{(1)}_{\kappa\mu} \partial^{\beta} \mu_{\nu\alpha\beta} \rangle = \frac{1}{4} \langle \square \Phi \square \Phi_{\mu\alpha} \rangle. \]  

(A26)

• Fourth term:

\[ \eta^{\nu\kappa} \langle \Gamma^{(1)}_{\kappa\mu} \partial^{\beta} \mu_{\nu\alpha\beta} \rangle = \frac{1}{8} \left[ \langle \square \Psi_{\lambda} \square \Psi^{\lambda} \rangle + \langle \square \Phi \square \Psi_{\mu} \rangle - \langle \partial_{\mu} \partial_{\alpha} \Psi_{\lambda} \square \Phi \rangle \right]. \]  

(A27)

• Fifth term:

\[ \frac{1}{2} \eta^{\mu\nu} \eta^{\beta\lambda} \langle R^{(1)}_{\mu\nu} C^{(1)}_{\nu\alpha\beta} \rangle = \frac{1}{8} \left( \langle \square \Psi_{\mu} \square \Psi_{\nu} \rangle + \langle \partial_{\mu} \partial_{\alpha} \Psi_{\nu} \square \Psi_{\nu} \rangle - \frac{1}{2} \eta_{\mu\alpha} \langle \square \Psi_{\nu} \square \Psi_{\nu} \rangle + \langle \square \Psi_{\mu} \square \Phi \rangle \right). \]  

(A28)

Substituting these five terms into \( \langle J^{(2)}_{\mu\alpha} \rangle \), we get

\[ \langle J^{(2)}_{\mu\alpha} \rangle = \frac{1}{4} \langle \square \Phi \square \Psi_{\mu\alpha} \rangle - \frac{1}{4} \langle \square \Psi_{\lambda} \square \Psi_{\mu\lambda} \rangle + \frac{1}{4} \langle \partial_{\alpha} \partial_{\mu} \Psi_{\nu} \square \Psi^{\nu} \rangle - \frac{1}{16} \eta_{\mu\alpha} \langle \square \Psi_{\nu} \square \Psi_{\nu} \rangle \]  

\[ = -\frac{1}{4\alpha} \langle \partial_{\mu} \Psi_{\nu} \partial_{\alpha} \Psi_{\nu} \rangle - \frac{1}{4\alpha^2} \langle \Psi_{\lambda} \partial_{\alpha} \Psi_{\lambda} \rangle - \frac{1}{16\alpha^2} \eta_{\mu\alpha} \langle \Psi_{\nu} \Psi_{\nu} \rangle. \]  

(A29)

Finally, to obtain the gravitational energy-momentum tensor \( t_{\mu\alpha} \), we substitute Eqs. \( \text{(A15)} \), \( \text{(A23)} \) and \( \text{(A29)} \) in the expression \( \text{(A1)} \). Thus,

\[ t_{\mu\alpha} = \frac{c^4}{8\pi G} \left[ \frac{1}{4} \langle \partial_{\mu} \hat{H}_{\nu\beta} \partial_{\alpha} \hat{H}_{\nu\beta} \rangle - \frac{1}{4} \langle \partial_{\mu} \Psi_{\nu} \partial_{\alpha} \Psi_{\nu} \rangle + \frac{1}{2} \langle \partial_{\mu} \hat{H}_{\nu\beta} \partial_{\alpha} \Psi_{\nu\beta} \rangle + \frac{3}{2} \langle \partial_{\alpha} \Phi \partial_{\mu} \Phi \rangle \right]. \]
