An effect of the Lorentz symmetry breaking is pointed out in the cosmological context. Using a Bianchi I geometry coupled to the Kalb–Ramond field, a consequence of the Lorentz symmetry violation is indicated by a different rate of expansion in a given spatial direction. This article focuses on the coupling constant $\xi$, which generates, from the Kalb–Ramond field, all three coefficients that give rise to the Lorentz violation in the gravity sector of the minimal Standard Model Extension. The coupling constant $\xi$ increases the rate of expansion of the universe in a given direction during a dark energy era. As a consequence, a range of validity of that coupling constant is also obtained.

Keywords: Lorentz Symmetry Breaking, Modified Gravity, Cosmology

I. INTRODUCTION

There is a common statement that both the Lorentz and the CPT symmetries violations would be fingerprints of a brand new physics at the Planck scale. It has been shown how such violations occur in different contexts, including string theory [1, 2], noncommutative field theory [3], quantum loop gravity [4, 5], and in the extra dimensions alternatives [6, 7]. A theoretical framework that includes a lot of possible Lorentz-violating effects and, at the same time, allows us to calculate modifications of quantities (that would be measured in experiments) is the Standard-Model Extension (SME) [8, 9]. The SME is an effective field theory that is in agreement with the gauge structure of the Standard Model (SM) of particle physics, allowing then the inclusion of Lorentz-violating coefficients that break the particle Lorentz invariance, but such coefficients still preserve the invariance under observer Lorentz transformations [10]. The gravitational sector of the SME was introduced in Ref. [11] and provides modifications on the Einstein–Hilbert term, including dynamic background fields coupled with both curvature and torsion.

Since its formulation in the late 1990s by Colladay and Kostelecký [8, 9], the SME has been conceived of as background for a variety of investigations like neutral meson oscillations [12], neutrino oscillations [13], clock-comparison tests [14], spin-polarized torsion pendulum [15], penning-trap tests of quantum electrodynamics [16], hydrogen and antihydrogen spectroscopy [17], muon decay [18], and optical and microwave cavities [19]. A large number of stringent constraints on Lorentz-violating coefficients were obtained in many sectors of the SME, especially for particles like photons, neutrinos, and leptons [1].

However, in contrast to the flat case, curved spacetimes do not support explicit Lorentz symmetry breaking (with fixed and nondynamical Lorentz-violating backgrounds) due to inconsistencies with both the Bianchi identities and conservation laws [11]. A mechanism capable of overcoming these difficulties is the spontaneous Lorentz symmetry breaking [21], which works similarly to the Higgs mechanism, adding then a potential term to the Lagrange density constructed in such a way that its minimum lies at a nonzero vacuum expectation value (VEV) for either the background vector field or the background tensor field [22, 24] (whether vector or tensor fields, such background fields are also called bumblebee fields). In this context, studying the behavior of gravity in the strong-field regime with the presence of spontaneous Lorentz violation is a tough task that has attracted attention in recent years, and several works involving solutions of compact objects like black holes [23, 28] and topologically nontrivial structures like wormholes [29, 30] have been carried out. In the cosmological scenario, effects of the Lorentz violation on the Friedmann-Lemaître-Robertson-Walker (FLRW) universe were studied in Refs. [31, 32, 41], and recently the impact of the Lorentz symmetry breaking on anisotropies of the cosmic microwave background radiation was examined by us in Ref. [33], in which the Bianchi type I geometry was assumed. In the latter work, we adopted a vector field in order to break the Lorentz symmetry. Here we will continue these investigations on Lorentz symmetry breaking, assuming an antisymmetric 2-tensor background field coupled to gravity in the Bianchi I geometry instead of a background vector field.

As we said, the geometry adopted here is the Bianchi type I, which generalizes the flat FLRW metric from the standard cosmology. The Bianchi I cosmology takes into consideration three independent scale factors, one for each spatial direction, and is able to disagree with the cosmological principle, promoting then an anisotropic universe [2]. In our previous work [33], the difference of

---

1 A compilation of several bounds can be found in Ref. [20].

2 See works on Bianchi I cosmology in several contexts [33, 12, 17].
a scale factor in a given direction (compared to others) comes from the bumblebee vector field. On the other hand, now we will adopt an antisymmetric 2-tensor background field, known in the literature as the Kalb–Ramond field \[34\], studied in other contexts in Refs. \[35, 36\]. It is worth emphasizing that a tensor field turns our task into an even more tough task. As we will see, for this case the background tensor field—by means of its equation of motion—give us a more stringent constraint compared to the background vector field case, although such a constraint is ruled out by recent observations.

As we mentioned before, the Kalb–Ramond field was adopted in several contexts. In cosmology, the context of this article, the authors of Refs. \[35, 36\] built solutions for the inflationary period in the \(F(R)\) gravity with the Kalb–Ramond tensor field. They were able to show that in the early universe such an antisymmetry tensor field could be important in the inflationary period. On the other hand, Ref. \[37\] adopted both the Einsteinian geometry and the nonminimal model for the Kalb–Ramond field (like us) in order to obtain a de Sitter phase and the inflationary period. But such works, in the cosmological context, chose the FLRW metric as the geometry of the universe, not the Bianchi I like our work, and do not assume the Lorentz symmetry breaking. Moreover, our focus is not on the early universe, our goals are the late universe (driven by dark energy) and a measurable effect due to the presence of a nonzero VEV for the Kalb–Ramond field, which breaks spontaneously the local Lorentz symmetry.

Regarding observations, here we intend to show the importance of a coupling constant from the SME on for the Kalb–Ramond field, which breaks spontaneously measurable effect due to the presence of a nonzero VEV. However, as we will see, here the gravitational field equations will not be linearized, thus the contributions of all three Lorentz-violating coefficients are still present. In a cosmological context, the role played by the \(t\)-coefficient was studied in the FLRW spacetime in Ref. \[41\]. But as we said, in this article we adopt the Bianchi I geometry. As we will see, the coupling constant \(\xi_1\), which is responsible for producing a nonzero VEV for the \(t^{\kappa\lambda\mu\nu}\) field (breaking then the Lorentz symmetry), increases the cosmic acceleration in a given direction during a dark energy era.

The article is structured as follows: in Sec. II the modified gravitational field equations are shown in the SME context, and all three Lorentz-violating coefficients are defined. In Sec. III the Bianchi I geometry is presented, and the Kalb–Ramond field is coupled to it. The Friedmann–like equations are obtained, and then the solution for a dark energy dominated universe is achieved in Sec. IV. The final remarks are in Sec. V.

II. THE MODIFIED GRAVITATIONAL SECTOR

According to Ref. \[29\], at leading order in the curvature, the most general action for the (bumblebee) Kalb–Ramond model is given by

\[
S = \int d^4x\sqrt{-g}\left[\frac{1}{2\kappa}R - \frac{1}{12} H_{\mu\nu\lambda}^3 - V + \mathcal{L}_M + \frac{1}{2\kappa}\right. \\
\left. \times \left(\xi_1 B^{\kappa\lambda} B^{\mu\nu} R_{\kappa\lambda\mu\nu} + \xi_2 B^{\lambda\mu} B^{\nu\rho} R_{\lambda\mu\nu\rho} + \xi_3 B^{\mu\nu} B_{\mu\nu} R\right)\right],
\]

(1)

where \(\kappa = 8\pi G_N/c^4\), such that \(G_N\) is the Newtonian gravitational constant, and \(c\) is the speed of light in vacuum. The Kalb–Ramond field, indicated by \(B_{\mu\nu}\), is an antisymmetric 2-tensor in the four-dimensional Riemannian manifold with its associated field-strength tensor \(H_{\mu\nu\lambda}\) defined by

\[
H_{\mu\nu\lambda} = \partial_\mu B_{\nu\lambda} + \partial_\nu B_{\lambda\mu} + \partial_\lambda B_{\mu\nu},
\]

(2)

with \(H_{\mu\nu\lambda}\) being invariant under the gauge transformation \(B_{\mu\nu} \rightarrow B_{\mu\nu} + \partial_\xi A_{\mu} - \partial_\mu A_\xi\). Also, the potential \(V\) is responsible for triggering spontaneously the Lorentz violation inducing then a nonzero VEV for the bumblebee field, that is to say,

\[
\langle B_{\mu\nu}\rangle = b_{\mu\nu}.
\]

(3)

In the same way, the potential induces a nonzero VEV for the dual tensor field \(\mathcal{B}_{\mu\nu}\), indicated as

\[
\langle \mathcal{B}_{\mu\nu}\rangle = \frac{1}{2}\epsilon_{\kappa\lambda\mu\nu} B^{\kappa\lambda} = \frac{1}{2}\epsilon_{\kappa\lambda\mu\nu} b^{\kappa\lambda},
\]

(4)

where \(\epsilon_{\kappa\lambda\mu\nu}\) is the totally antisymmetric Levi-Civita tensor. In general, the potential \(V\) depends on \(B_{\mu\nu}\) through the \(B_{\mu\nu} B^{\mu\nu}\) and \(B_{\mu\nu} B^{\mu\nu}\) scalars. However, as we will see in this work, the explicit form of the potential will not be relevant in our analysis.

Following the final terms of Eq. (1), \(\mathcal{L}_M\) regards the matter (or energy) content that will be specified later, the coupling constants \(\xi_1, \xi_2, \) and \(\xi_3\) represent all non-minimal nonderivative gravitational couplings to the field

\footnote{Recently, an exception is made in Ref. \[48\], in which one of us studied that coefficient using a wormhole geometry.}
\( B_{\mu \nu} \) (tensorial constants that are linear in the curvature, \( R \), \( R_{\mu \nu} \), and \( R_{\alpha \beta \lambda \mu} \) are the scalar curvature, the Ricci tensor and the Riemann tensor, respectively.

On the other hand, the minimal gravitational sector of the SME can be written as

\[
S_{\text{LV}}^{(\text{min})} = \int d^4x \sqrt{-g} \left( -uR + s^{\mu \nu} R_T^\mu + t^{\kappa \lambda \mu \nu} C_{\kappa \lambda \mu \nu} \right),
\]

where \( R_T^\mu \) is the trace-free Ricci tensor, and \( C_{\kappa \lambda \mu \nu} \) is the Weyl conformal tensor. In order to satisfy both the geometric constraints of Riemann-Cartan manifolds and the conservation laws of general relativity, the coefficients \( u \), \( s^{\mu \nu} \) and \( t^{\kappa \lambda \mu \nu} \), must be functions of spacetime position, and their underlying dynamics will depend on the choice of the specific model. In particular, the theory described by action (1) is capable of generating the necessary dynamics for all three SME coefficients, and the correspondence with the Kalb–Ramond field \( B_{\mu \nu} \) can be read in the following form:

\[
u_B = -\left( \frac{1}{6} \xi + \frac{1}{4} \xi_2 + \xi_3 \right) B^{\alpha \beta} B_{\alpha \beta}, \quad (6)
\]

\[
s_B^{\mu \nu} = (2 \xi_1 + \xi_2) \left( B^\mu_\alpha B^\nu_\alpha - \frac{1}{4} g^{\mu \nu} B^{\alpha \beta} B_{\alpha \beta} \right), \quad (7)
\]

\[
t_B^{\kappa \lambda \mu \nu} = \frac{2}{3} \xi_1 \left( B^{\kappa \lambda} B^{\mu \nu} + \frac{1}{2} B^\kappa_\mu B^\lambda_\nu - \frac{1}{2} B^\nu_\kappa B^\mu_\lambda \right) - \frac{1}{2} \xi_1 \left( g^{\mu \nu} B^\kappa_\lambda B^{\alpha \beta} - g^{\kappa \lambda} g^{\mu \nu} B^\alpha_\beta \right) - g^{\mu \nu} B^\kappa_\lambda B^{\alpha \beta} B_{\alpha \beta} + \frac{1}{6} \xi_1 \left( g^{\mu \nu} g^{\kappa \lambda} - g^{\kappa \lambda} g^{\mu \nu} \right) B^{\alpha \beta} B_{\alpha \beta}. \quad (8)
\]

It is worth emphasizing that the spontaneous Lorentz-breaking effects controlled by the fields or coefficients \( u \), \( s^{\mu \nu} \) and \( t^{\kappa \lambda \mu \nu} \) have been widely explored topics. In particular, black hole solutions and anisotropies in the cosmic microwave background radiation were recently investigated by us in Refs. \[25, 33\]. However, the description of that effects depends on the fields that are chosen to compose the mentioned coefficients. In particular, the physics and consequently the phenomenology of the t-coefficient can not be achieved by vector fields (adopted by us in the mentioned works), it requires the presence of an antisymmetric 2-tensor, being the least explored in the literature so far. Thus, as we said in Introduction, our main focus will be on the coupling constant \( \xi_1 \), which is responsible for producing a nonzero VEV for the field \( t_B^{\kappa \lambda \mu \nu} \).

Varying the action (1) with respect to the metric tensor, one obtains the modified gravitational field equations:

\[
G^{\mu \nu} = \kappa T_M^{\mu \nu} + \kappa T_B^{\mu \nu} + T_{\xi_1}^{\mu \nu} + T_{\xi_2}^{\mu \nu} + T_{\xi_3}^{\mu \nu}. \quad (9)
\]

The left side of (9) is the usual Einstein tensor \( G_{\mu \nu} = R_{\mu \nu} - \frac{1}{2} R g_{\mu \nu} \), as the terms on the right side represent energy-momentum tensors whose sources are both the matter content \( T_M^{\mu \nu} \) and the Kalb–Ramond field \( B_{\mu \nu} \).

Contributions in Eq. (9) due to the Kalb–Ramond field come from the kinetic and potential terms in \( T_B^{\mu \nu} \) and the three couplings, \( T_{\xi_1}^{\mu \nu} \), \( T_{\xi_2}^{\mu \nu} \), and \( T_{\xi_3}^{\mu \nu} \). For \( B_{\mu \nu} \)-terms, we have explicitly

\[
T_{\xi_1}^{\mu \nu} = \frac{1}{2} H^{\alpha \beta \mu} H_{\alpha \beta} - \frac{1}{12} g^{\mu \nu} H^{\alpha \beta \gamma} H_{\alpha \beta \gamma} - g^{\mu \nu} V + 4 B^{\alpha \mu} B_{\alpha \nu} V', \quad (10)
\]

in which the operator (\( ' \)) stands for derivative with respect to the potential argument, and for the sake of simplicity the dependence of the potential \( V \) with respect to \( B_{\mu \nu} \) is assumed in the form

\[
V \equiv V(B_{\mu \nu} B^{\mu \nu} - x), \quad (11)
\]

with \( x \) playing the role of a real number, meaning the VEV of the following invariant

\[
x \equiv \langle B_{\mu \nu} B^{\mu \nu} \rangle = \langle g^{\mu \nu} \rangle b_{\alpha \beta} b_{\mu \nu}. \quad (12)
\]

Note that \( \langle g^{\mu \nu} \rangle \) is the VEV of the inverse metric. Since we are interested in investigating the Lorentz-violating effects due to a nonzero VEV for the \( B_{\mu \nu} \) field, we restrict ourselves to the case where the primary fields are frozen in their vacuum values, i.e.,

\[
B_{\mu \nu} = b_{\mu \nu}, \quad g_{\mu \nu} = \langle g_{\mu \nu} \rangle, \quad (13)
\]

breaking then both the local Lorentz and diffeomorphism symmetries. Also, the extreme conditions \( V = V' = 0 \), which fix the vacuum state, are assumed and satisfied here.

The remaining terms in Eq. (9) originated from the nonminimal gravitational couplings are explicitly written as

\[
\begin{align*}
T_{\xi_1}^{\mu \nu} &= \xi_1 \left( \frac{1}{2} g^{\mu \nu} B^{\alpha \beta} B_{\gamma \delta} R_{\alpha \beta \gamma \delta} + \frac{3}{2} B^{\beta \gamma} B^{\alpha \mu} R_{\alpha \beta \mu} 
+ \frac{3}{2} B^{\beta \gamma} B^{\alpha \mu} R_{\alpha \beta \mu} + \nabla_\alpha \nabla_\beta B^{\alpha \beta} - \nabla_\alpha \nabla_\beta B^{\alpha \mu} B_{\mu \beta} \right), \quad (14)
\end{align*}
\]

\[
\begin{align*}
T_{\xi_2}^{\mu \nu} &= \xi_2 \left( \frac{1}{2} g^{\mu \nu} B^{\alpha \gamma} B_{\beta \gamma} R_{\alpha \beta} - B^{\alpha \gamma} B_{\beta \mu} R_{\alpha \beta} - B^{\alpha \gamma} B_{\beta \mu} R_{\alpha \beta} 
+ \frac{1}{2} \nabla_\alpha \nabla_\mu B_{\beta \mu} B_{\alpha \beta} + \frac{1}{2} \nabla_\alpha \nabla_\mu B_{\beta \mu} B_{\alpha \beta} 
- \frac{1}{2} \nabla_\beta B^{\alpha \mu} B_{\alpha \gamma} \nabla_\beta B^{\alpha \gamma} \right), \quad (15)
\end{align*}
\]

and

\[
\begin{align*}
T_{\xi_3}^{\mu \nu} &= \xi_3 \left( \nabla_\mu \nabla_\nu B^{\alpha \beta} B_{\alpha \beta} - g^{\mu \nu} \nabla_\alpha \nabla_\beta B^{\alpha \beta} + B^{\alpha \beta} B_{\alpha \beta} G^{\mu \nu} + 2 B^{\alpha \mu} B^{\beta \nu} R_{\alpha \beta} \right). \quad (16)
\end{align*}
\]
Now varying the action with respect to the antisymmetric tensor field \( B_{\mu\nu} \), keeping the metric and matter fields fixed, gives us the field equations for the Kalb–Ramond field, namely
\[
\nabla_\alpha H^{\alpha\mu\nu} = J^{\mu\nu}_V + J^{\mu\nu}_R,
\]
with the potential current \( J^{\mu\nu}_V \) written in the form
\[
J^{\mu\nu}_V = 4V^\prime B^{\mu\nu},
\]
and the curvature current \( J^{\mu\nu}_R \) being given by
\[
J^{\mu\nu}_R = \frac{-2\xi_1}{\kappa} B_{a\beta} R^{a\beta\mu\nu} + \frac{\xi_2}{\kappa} B_{a}[\mu R^{\rho]\alpha] - \frac{2\xi_3}{\kappa} B^{\mu\nu} R. \tag{19}
\]
It is worth pointing out that here we are explicitly disregarding any coupling between the matter fields and the Kalb–Ramond field. Such a possibility (a particular coupling between matter and \( B_{\mu\nu} \)) may imply changes in the conservation of the conventional matter currents, something beyond our scope in this article.

The conservation of the total current is immediately achieved from the choice of the kinetic term for the field \( B_{\mu\nu} \), satisfying then the condition
\[
\nabla_\mu (J^{\mu\nu}_V + J^{\mu\nu}_R) = 0. \tag{20}
\]
Alternatively, assuming that the energy-momentum tensor from the matter content is covariantly conserved \((\nabla_\mu T^{\mu\nu}_M = 0)\), alongside the Bianchi identity for the Einstein tensor, that is \( \nabla_\mu G^{\mu\nu} = 0 \), then the components \( T^{\mu\nu}_B, T^{\mu\nu}_{\xi_1}, T^{\mu\nu}_{\xi_2}, \) and \( T^{\mu\nu}_{\xi_3} \) of the total energy-momentum tensor also lead to the condition
\[
\kappa \nabla_\mu T^{\mu\nu}_B = -\nabla_\mu \left( T^{\mu\nu}_{\xi_1} + T^{\mu\nu}_{\xi_2} + T^{\mu\nu}_{\xi_3} \right). \tag{21}
\]
As we mentioned earlier, we are going to focus on the phenomenology of the \( \xi_1 \) coupling constant of the modified field equations. That means the couplings \( \xi_2 \) and \( \xi_3 \) are set to zero from here.

### III. THE GEOMETRY AND THE BACKGROUND FIELD

#### A. The Bianchi type I metric and the Kalb–Ramond field

In order to study the influence of the coupling constant \( \xi_1 \) on the spacetime dynamics, we assume the Bianchi I geometry as the cosmological spacetime, allowing then that spatial directions are different from each other, illustrating (as we will see) an effect of the Lorentz symmetry violation on spacetime. The Bianchi I metric (or line element) in the Cartesian coordinates \((x_1, x_2, x_3)\) is written simply as
\[
ds^2 = -c^2 dt^2 + a_1(t)^2 dx_1^2 + a_2(t)^2 dx_2^2 + a_3(t)^2 dx_3^2, \tag{22}
\]
in which \( a_1(t), a_2(t), \) and \( a_3(t) \) are scale factors for each spatial direction, \((x_1, x_2, x_3)\) respectively. Thus, the Hubble parameter is defined for each spatial direction, i.e.,
\[
H_i = \frac{\dot{a}_i(t)}{a_i(t)}, \text{ with } i=1,2,3, \tag{23}
\]
where dot means derivative with respect to the time coordinate \( t \) or the cosmic time. Therefore, in this context, contrary to the FLRW cosmology, we could have different directional Hubble parameters.

Now let us set the vacuum value of the Kalb–Ramond field \( B_{\mu\nu} \) in order to describe its influence on the spacetime dynamics. In four dimensions, an antisymmetric 2-tensor like the Kalb–Ramond field can be decomposed into two independent 3-vectors like
\[
b_{0i} = -\Sigma^i \quad \text{and} \quad b_{jk} = \epsilon_{jkl}\Xi^l. \tag{24}
\]
This is similar to the electric and magnetic decomposition of the field strength \( F_{\mu\nu} \) in Maxwell electrodynamics. Here the 3-vector fields \( \Sigma \) and \( \Xi \) encode the six degrees of freedom of the vacuum value \( b_{\mu\nu} \). However, it is always possible to perform local observer Lorentz transformations in order to rewrite \( b_{\mu\nu} \) in a simple block-diagonal form. For our purpose, following Ref. [39], this simple and special form can be conceived of as
\[
b_{\mu\nu} = \begin{pmatrix} 0 & -Aa_1 & 0 & 0 \\ Aa_1 & 0 & 0 & 0 \\ 0 & 0 & 0 & B(a_2a_3) \\ 0 & 0 & -B(a_2a_3) & 0 \end{pmatrix}, \tag{25}
\]
where \( A \) and \( B \) are real numbers (as we pointed out, both are interpreted as the “electric” and “magnetic” parts, respectively, of the bumblebee field). In this special frame \( x = b_{\mu\nu}b^{\mu\nu} = -2(\frac{\dot{a}_2}{a_2} - B^2) \), ensuring that \( b_{\mu\nu} \) produces a constant invariant scalar. Besides, our analysis is simplified as we have now only two Lorentz-violating parameters \((A \text{ and } B)\) instead of six initial parameters that remain for a general case.

Consequently, the field strength \( H_{\mu\nu\lambda}, \) defined in Eq. (2), is not identically zero according to the field \( b_{\mu\nu} \) chosen in Eq. (25). There are six nonzero components, namely
\[
H_{023} = -H_{032} = H_{230} = -H_{203} = H_{302} = -H_{320} = B(a_2a_3). \tag{26}
\]
As is clear from Eq. (17), such components will be used in the calculations of the Kalb–Ramond field equations.

#### B. The energy-momentum tensor(s)

In order to describe the matter-energy content, which will be a single component (excluding the background field), we assume the perfect fluid interpretation, which
will allow us to describe the Kalb–Ramond field influence on the cosmic expansion. Therefore, the matter-energy content will be indicated by the tensor

\[ T_{\mu \nu}^M = \left[ \rho_M(t) + \frac{p_M(t)}{c^2} \right] u^\mu u^\nu + p_M(t)g^{\mu \nu}, \]  

(27)

in which \( \rho_M(t) \) and \( p_M(t) \) stand for the density and pressure, respectively, of the matter-energy content (as we will see the bumblebee field or the Kalb–Ramond field has its own energy-momentum tensor). The four-vector \( u^\mu \) is the four-velocity of the fluid, and, in particular for the metric signature adopted here, \( u_\mu u^\mu = -c^2 \). Like our previous work [33], the matter-energy content is an isotropic fluid, and, as we will see, anisotropies come from the Kalb–Ramond field.

On the other hand, the corresponding Kalb–Ramond energy-momentum tensor in the Bianchi I cosmology, from the specific form of that field, given by Eq. (25), reads

\[ (T_B)^\mu_\nu = \begin{pmatrix} -\rho_B c^2 & p_1 \\ p_2 & p_3 \end{pmatrix}, \]  

(28)

with

\[ -\rho_B c^2 = -p_1 = p_2 = p_3 = -\frac{B^2}{2c^2} (H_2 + H_3)^2. \]  

(29)

Thus, contrary to the energy-momentum tensor for the matter field, it is evident the anisotropic feature of the \( T_B^{\mu \nu} \) field. As we can straightforwardly read, pressure in the \( x_1 \) direction is different from other directions. Later we will assume that the \( x_2 \) and \( x_3 \) directions are identical ones, then \( H_2 = H_3 \).

For the coupling \( \xi_1 \), its respective energy-momentum tensor is written as

\[ (T_{\xi_1})^\mu_\nu = \begin{pmatrix} -\rho_{\xi_1} c^2 & p_1 \\ p_2 & p_3 \end{pmatrix}, \]  

(30)

with

\[ -\rho_{\xi_1} c^2 = -\frac{2\xi_1}{c^2} \left\{ \frac{H_1 H_2 + H_1 H_3 - 2 (H_1 + H_2)^2}{c^2} \right\} + B^2 H_2 H_3, \]  

(31)

\[ P_1 = -\frac{2\xi_1}{c^2} \left\{ \frac{H_2 + H_3 - 2 (H_1 + H_2^2) + (H_2 + H_3)^2}{c^2} \right\} + \frac{A^2}{c^2} - B^2 H_2 H_3 \}, \]  

(32)

\[ P_2 = -\frac{2\xi_1}{c^2} \left\{ \frac{H_1 + H_2^2}{c^2} + \frac{H_3 + H_3 (H_1 + 2H_2)}{c^2} \right\} + (H_3) B^2 \}, \]  

(33)

\[ P_3 = -\frac{2\xi_1}{c^2} \left\{ \frac{H_1 + H_2^2}{c^2} + \frac{H_2 + H_2 (H_1 + 2H_2)}{c^2} + 2H_3 \right\} B^2 \}. \]  

(34)

In this case, all three pressures could be different. But as we said, due to the \( T_B^{\mu \nu} \) components, the \( P_2 \) and \( P_3 \) components will be conceived of as identical ones.

**C. The Friedmann-like equations**

From the modified field equations [25], the background field [25] and the total energy-momentum tensor \( (T_T^{\mu \nu} = T_M^{\mu \nu} + T_B^{\mu \nu} + T_{\xi}^{\mu \nu} \), we are able to write the Friedmann-like equations in the Bianchi I cosmology in the context studied here. By doing several calculations, we have the following components:

\[ H_1 H_2 + H_1 H_3 + H_2 H_3 = 8\pi G (\rho_M + \rho_B + \bar{\rho}_{\xi}), \]  

(35)

\[ \dot{H}_2 + \dot{H}_3 + \dot{H}_2^2 + \dot{H}_3^2 + 2H_2 H_3 = -\frac{8\pi G}{c^2} (p_M + p_1 + \bar{P}_1), \]  

(36)

\[ \dot{H}_1 + \dot{H}_3 + \dot{H}_1^2 + \dot{H}_3^2 + 2H_1 H_3 = -\frac{8\pi G}{c^2} (p_M + p_2 + \bar{P}_2), \]  

(37)

\[ \dot{H}_1 + \dot{H}_2 + \dot{H}_1^2 + \dot{H}_2^2 + 2H_1 H_2 = -\frac{8\pi G}{c^2} (p_M + p_3 + \bar{P}_3), \]  

(38)

where \( \bar{\rho}_{\xi} = \rho_{\xi}/\kappa \) and \( \bar{P}_i = P_i/\kappa \), with \( i = 1, 2, 3 \).

It is worth calculating the mean Hubble parameter, which is defined as

\[ H = \frac{1}{3} (H_1 + H_2 + H_3). \]  

(39)

Then by using Eqs. (35)-(38), one has a Friedmann-like equation also for the mean Hubble parameter, that is,

\[ \dot{H} + 3H^2 = 4\pi G \left\{ \frac{\rho_M + 3\rho_B + \bar{\rho}_{\xi}}{c^2} \right\} - \frac{1}{c^2} \left\{ \rho_M + \frac{1}{3} (\bar{P}_1 + \bar{P}_2 + \bar{P}_3) \right\}, \]  

(40)

which will be very useful later.
D. Constraints from the background field equations

The Kalb–Ramond field equations, that is to say Eq. (17), provides, after adopting the Bianchi I metric and the tensor field (20), the following two constraints. It is worth emphasizing that Eq. (20), which shows the current conservation, is satisfied only when the two constraints are adopted.

First constraint

The first one comes from the \( \mu = 0 \) and \( \nu = 1 \) component (which is equal to the minus \( \mu = 1 \) and \( \nu = 0 \) component) of that equation of motion, which is written as

\[
\frac{4A_1\bar{a}_1}{\kappa c^2 a_1^2} = 0. \tag{41}
\]

The above constraint implies that either \( A = 0 \) or \( \bar{a}_1 = 0 \). The latter is ruled out by well-known reports [19-51], that is, with \( \bar{a}_1 = 0 \) one has a null deceleration parameter

\[ q_1 = -\frac{\ddot{a}_1}{\dot{a}_1^2} = 0 \]

in the \( x_1 \) direction or, equivalently, absence of an accelerated expansion in that direction. It is worth pointing out that such a constraint is more stringent than that one obtained as the bumblebee field is a vector field [33], although in the case presented here this stringent constraint is ruled out by observations. Having said that, we then assume—from the constraint (41)—that \( A = 0 \) in the next calculations, i.e., the “electric” part of \( b_{\mu\nu} \) is null.

Second constraint

The second constraint from the Kalb–Ramond field equations (17) is given by

\[
\dot{H}_2 + \dot{H}_3 + H_1(H_2 + H_3) - \frac{4A_1}{\kappa} H_2 H_3 = 0. \tag{42}
\]

It comes from the \( \mu = 2 \) and \( \nu = 3 \) component (again, it is equal to the minus \( \mu = 3 \) and \( \nu = 2 \) component). The two constraints will be very useful in order to solve the Friedmann-like equations. Another useful simplification comes from the fact that \( p_2 = p_3 \), according to the Kalb–Ramond energy-momentum tensor indicated in Eq. (20). Therefore, as we said, the directions \( x_2 \) and \( x_3 \) will be considered equivalent. From that assumption, the constraint (42) and the \( \mu = \nu = 1 \) component of the Friedmann-like equations, given by Eq. (30), lead to

\[
H^2_j = \frac{\kappa^2 c^2}{4(\kappa + \xi_1)} \left( \rho_{MC}^2 - p_M \right), \quad \text{for } j = 2, 3. \tag{43}
\]

Note that the above result is obtained just for the \( A = 0 \) case.

E. Energy-momentum conservation

For a reliable physical model, the conservation of the energy-momentum tensor should be satisfied. Here the energy-momentum conservation, namely \( \nabla_\nu T^{\mu\nu}_M = \nabla_\nu(\kappa T^{\mu\nu}_M + \kappa B^{\mu\nu} + \kappa_1 T^{\mu\nu}_1) = 0 \), is valid by using the two constraints mentioned before. With the aid of (11)-(12), then the energy-momentum conservation leads to the well-known equation, i.e.,

\[
\dot{\rho}_M = -3H \left( \rho_M + \frac{p_M}{c^2} \right). \tag{44}
\]

As we can see, the Kalb–Ramond field does not couple with the matter fields.

IV. SOLVING THE FRIEDMANN-LIKE EQUATIONS FOR A DARK ENERGY DOMINATED UNIVERSE

In order to solve the complicated system of equations (35)-(38), we follow our previous work [33] in which the Bianchi I geometry is conceived of as a small deviation from the FLRW metric. Contrary to the quoted work, we are dealing with a tensor field, instead of a vector field like in the previous work. It is worth emphasizing that we are working on the late universe, not on the early universe and the inflationary period with a Kalb–Ramond field like Refs. [35-57]. Most importantly, the motivation here is not to assign the antisymmetric background field as source of the dark energy, but to indicate the origin of anisotropies in the accelerated expansion phase by means of the Kalb–Ramond field in the Lorentz symmetry breaking context. And, as we will see, anisotropies of that type will be given by different directional Hubble parameters.

From the Friedman-like equations (35)-(38), and with the aid of the mean Hubble parameter (40), we have

\[
\dot{H}_1 + 3H H_1 = 4\pi G (1 + \delta) \left( \rho_M - \frac{p_M}{c^2} \right), \tag{45}
\]

\[
\dot{H}_j + 3H H_j = 4\pi G \left( \rho_M - \frac{p_M}{c^2} \right), \tag{46}
\]

where the dimensionless parameter \( \delta \) is defined as

\[
\delta = 2(\kappa + \xi_1) B^2, \tag{47}
\]

with \( 0 < \delta < 1 \). As we can see, the geometry studied here also can be conceived of as a small deviation from the FLRW metric. With \( \delta = 0 \), the Friedmann equations in the FLRW context are restored. As we note in Eq. (17), setting \( \xi_1 = 0 \) does not eliminate \( \delta \) or even an effect of the Lorentz symmetry breaking on the geometry. This is due to the fact that there is still a contribution from the “magnetic” part of the Kalb–Ramond field, the kinetic term in the action (11).

Eqs. (45) and (46) provide a simpler equation for the mean Hubble parameter, that is to say, adding up those
components one has
\[
\dot{H} + 3H^2 = 4\pi G \left( 1 + \frac{\delta}{3} \right) \left( \rho_M - \frac{p_M}{c^2} \right). \tag{48}
\]
Thus, from the equation for the mean Hubble parameter, solutions of \(44\) and \(46\) are straightforwardly written as
\[
H_1(t) = \frac{1}{\mu(t)} \left[ K_1 + \int^t \mu(t') 4\pi G \left( \rho_M - \frac{p_M}{c^2} \right) dt' \right], \tag{49}
\]
for the component in the \(x_1\) direction, and
\[
H_j(t) = \frac{1}{\mu(t)} \left[ K_j + \int^t \mu(t') 4\pi G \left( \rho_M - \frac{p_M}{c^2} \right) dt' \right], \tag{50}
\]
in which, as we said, \(j = 2, 3\) are the components in the \(x_2\) and \(x_3\) directions, respectively. In the above equations, \(K_i\) (with \(i = 1, 2, 3\)) are integration constants, and the function \(\mu(t)\) is defined as
\[
\mu(t) = \exp \left( \int^t 3H(s) ds \right). \tag{51}
\]
Like our previous work \(33\), the constants \(K_i\) are set to zero. Therefore, the difference from each spatial direction is given just by the influence of the Kalb–Ramond field on the spacetime geometry. Without the Kalb–Ramond field, in the general relativity realm, the difference from each directional Hubble parameter comes from those integration constants. Adopting the background field brings us a physical origin for the difference among each directional Hubble parameter, without considering the integration constants \(K_i\).

For a dark energy dominated universe, let us adopt the following equation of state for the cosmic fluid: \(\omega_{DE} = p_{DE}/\rho_{DE} c^2 = -1\) (which is equivalent to a vacuum spacetime, or \(T_{\mu\nu} = 0\), with a cosmological constant). Consequently, from Eq. \(14\), the dark energy density is constant, i.e., \(\rho_{DE} = 0\). Then the mean Hubble parameter equation, indicated by Eq. \(18\), give us as solution
\[
H_{DE} = \left[ \frac{8\pi G}{3} \left( 1 + \frac{\delta}{3} \right) \rho_{DE} \right]^{\frac{1}{2}}. \tag{52}
\]
With the mean Hubble parameter, in this case for a dark energy dominated universe, we are able to calculate the directional Hubble parameters \(49\) and \(50\) with the aid of Eq. \(51\). After calculating them, one has
\[
H_1 = (1 + \delta) \left[ \frac{8\pi G}{3(3 + \delta)} \rho_{DE} \right]^{\frac{1}{2}}, \tag{53}
\]
\[
H_j = \left[ \frac{8\pi G}{3(3 + \delta)} \rho_{DE} \right]^{\frac{1}{2}}. \tag{54}
\]
For \(\delta = 0\), the constant Hubble parameter \(H_0\) for a dark energy dominated universe in the FLRW perspective is restored, i.e., \(H_1 = H_j = H_{DE} = H_0 = \left( \frac{8\pi G \rho_{DE}}{3} \right)^{\frac{1}{2}}\).

With the directional Hubble parameters, it is easy to get the corresponding scale factors, according to the definition \(20\). Thus,
\[
a_1(t) = \exp \left( \int H_1(t-t_0) dt \right), \tag{55}
a_j(t) = \exp \left( \int H_j(t-t_0) dt \right), \tag{56}
\]
in which \(t_0\) is the present time or the age of the universe. According to Fig. \(1\) the Kalb–Ramond field affects the \(x_1\) direction accelerating it, showing then that the \(x_1\) direction has an expansion phase faster than other spatial directions. As this very difference comes from the parameter \(\delta\) and, consequently, from the coupling constant \(\xi_1\), then we describe with that scale factors the influence of that coupling constant on the spacetime dynamics, its phenomenology in this simplified case.

Lastly, the constraint \(43\) and the above solution for \(H_j\) in a dark energy dominated universe give us
\[
\delta = \frac{2\xi_1 - \kappa}{\kappa}. \tag{57}
\]
Therefore, by using the definition of \(\delta\), given by Eq. \(17\), we have the following value for the Lorentz-violating parameter \(B\) and, consequently, for the norm of the Kalb–Ramond or bumblebee field in the VEV, namely
\[
B^2 = \frac{2\xi_1 - \kappa}{2\kappa(\kappa + \xi_1)} \quad \text{and} \quad b_{\mu\nu}b^{\mu\nu} = \frac{2\xi_1 - \kappa}{\kappa(\kappa + \xi_1)}. \tag{58}
\]
On the other hand, assuming Eq. \(17\) and Eq. \(57\), with \(0 < \delta < 1\), that is, our cosmological solution is a small deviation from the FLRW spacetime, we have an interesting range of validity of the coupling constant \(\xi_1\), i.e.,
\[
\frac{\kappa}{2} < \xi_1 < \kappa. \tag{59}
\]
producing then Lorentz symmetry breaking effects on a geometry that is close to the standard geometry in cosmology.

V. FINAL REMARKS

Lorentz symmetry violation has been a fruitful area in theoretical physics in the last decades. The idea that violations of that symmetry can reveal hints of a quantum theory of gravity is an attracting topic. Here we studied the spontaneous Lorentz violation caused by an antisymmetric tensor field, the Kalb–Ramond field. In particular, we focused on the coupling constant $\xi_1$, the least studied in the literature, which is the coupling that generates all three Lorentz-violating coefficients. And such coefficients are responsible for triggering the spontaneous Lorentz violation in the SME, which is the context adopted in this article.

The phenomenology of the coupling $\xi_1$ was analyzed using the Bianchi I metric as the cosmological spacetime, a spacetime that is not in agreement with the cosmological principle. In that context, the cosmological one, the Lorentz-violating coupling produced a small deviation from the standard geometry in cosmology, namely the FLRW geometry, inducting then a faster acceleration in a given spatial direction during a dark energy era. Therefore, a phenomenological aspect of the coupling constant $\xi_1$ was brought out in this article, and also a range of validity for that coupling constant was achieved.

Lastly, as a development of ideas from this article, the inflationary period could be studied in a future work by assuming both the Kalb–Ramond field within the Lorentz symmetry breaking context (something that is missing in inflation models) and the Bianchi I cosmology in order to reproduce an anisotropic inflationary model.
