THE LOG-SOBOLEV INEQUALITY WITH QUADRATIC INTERACTIONS.

IOANNIS PAPAGEORGIOU

Abstract. We assume one site measures without a boundary $e^{-\phi(x)}dx/Z$ that satisfy a log-Sobolev inequality. We prove that if these measures are perturbed with quadratic interactions, then the associated infinite dimensional Gibbs measure on the lattice always satisfies a log-Sobolev inequality. Furthermore, we present examples of measures that satisfy the inequality with a phase that goes beyond convexity at infinity.

1. Introduction

We focus on the logarithmic Sobolev inequality for unbounded spin systems on the $d$-dimensional lattice $\mathbb{Z}^d$ ($d \geq 1$) with quadratic interactions. The aim of this paper is to prove that when the single site measure without interactions (consisting only of the phase)

$$\mu(dx) = \frac{e^{-\phi(x)}dx}{\int e^{-\phi(x)}dx}$$

satisfies the log-Sobolev inequality, then the Gibbs measure of the associated local specification $\{E_{\Lambda,\omega}\}_{\Lambda \subset \mathbb{Z}^d, \omega \in M^\partial \Lambda}$, with Hamiltonian

$$H^{\Lambda,\omega}(x_\Lambda) := \sum_{i \in \Lambda} \phi(x_i) + \sum_{i,j \in \Lambda, j \sim i} J_{ij}V(x_i, x_j) + \sum_{i \in \Lambda, j \in \partial \Lambda, j \sim i} J_{ij}V(x_i, \omega_j),$$

also satisfies a log-Sobolev inequality, when the interactions $V$ are quadratic.

Since the main condition about the phase measure does not involve the local specification $\{E_{\Lambda}\}$ nor the one site measure $E^{(i)}_{\omega}$, we present a criterion for the infinite dimensional Gibbs measure inequality without assuming or proving the usual Dobrushin and Shlosman’s mixing conditions for the local specification as in [S-Z] and more recently in [M2]. As a matter of fact, in order to control the boundary conditions involved in the interactions, we will make use of the U-bound inequalities introduced in [H-Z] to prove coercive inequalities in a standard non statistical mechanics framework. As a result we prove the inequality for a variety of phases extending beyond the usual Euclidean case, as well as involving measures with phase like

$$\phi(x) = d^p(x) + \cos(d(x))d^{p-1}(x), \quad p \geq 2$$

that go beyond the typical convexity at infinity.

For the investigation of criteria for the logarithmic Sobolev inequality for the infinite dimensional Gibbs measure of the local specification \( \{ E^\Lambda, \omega \}_{\Lambda \subset \mathbb{Z}^d, \omega \in M^\partial \Lambda} \) two main approaches have been developed.

The first approach is based in proving first that the measures \( \{ E^\Lambda, \omega \}_{\Lambda \subset \mathbb{Z}^d, \omega \in M^\partial \Lambda} \) satisfy a log-Sobolev inequality with a constant uniformly on the set \( \Lambda \) and the boundary conditions \( \omega \). Then the inequality for the Gibbs measure follows directly from the uniform inequality for the local specification. Criteria for the local specification to satisfy a log-Sobolev inequality uniformly on the set \( \Lambda \) and the boundary conditions have been investigated by \([Z2], [B], [B-E], [Y], [A-B-C], [B-H]\) and \([H]\). Similar results for the weaker spectral gap inequality have been obtained by \([G-R]\).

The second approach focuses in obtaining the inequality for the Gibbs measure directly, without showing first the stronger uniform inequality for the local specification. Such criteria on the local specification in the case of quadratic interactions for the infinite-dimensional Gibbs measure on the lattice have been investigated by \([Z1], [Z2]\) and \([G-Z]\).

The problem of passing from the single site to infinite dimensional measure, in the case of quadratic interactions, is addressed by \([M1], [L-P]\) and \([O-R]\). What it has been shown is that when the one site measure \( E^{\{i, \omega\}} \) satisfies a log-Sobolev inequality uniformly on the boundary conditions, then in the presence of quadratic interactions the infinite Gibbs measure also satisfies a log-Sobolev inequality.

For the single-site measure \( E^{\{i, \omega\}} \), necessary and sufficient conditions for the log-Sobolev inequality to be satisfied uniformly over the boundary conditions \( \omega \), are also presented in \([B-C], [B-Z]\) and \([R-Z]\).

The scope of the current paper is to prove the log-Sobolev inequality for the Gibbs measure without setting conditions neither on the local specification \( \{ E^\Lambda \} \) nor on the one site measure \( E^{\{i, \omega\}} \). What we actually show is that in the presence of quadratic interactions, the Gibbs measure always satisfies a log-Sobolev inequality whenever the boundary free one site measure \( \mu(dx) = e^{-\phi(x)}dx/(\int e^{-\phi(x)}dx) \) satisfies a log-Sobolev inequality. In that way we improve the previous results since the log-Sobolev inequality is determined alone by the phase \( \phi \) of the simple without interactions measure \( \mu \) on \( M \), for which a plethora of criteria and examples of good measure that satisfy the inequality exist.

2. General framework and main result.

We consider the \( d \)-dimensional integer lattice \( \mathbb{Z}^d \) with the standard neighborhood notion, where two lattice points \( i, j \in \mathbb{Z}^d \) are considered neighbours if their lattice distance is one, i.e. they are connected with an edge, in which case we write \( i \sim j \). We will also denote \( \{ \sim i \} \) for the set of all neighbours of a node \( i \) and \( \partial \Lambda \) the boundary of a set \( \Lambda \subset \mathbb{Z}^d \). Our configuration space is \( \Omega = M^\mathbb{Z}^d \), where \( M \) is the spin space.

We consider unbounded \( n \)-dimensional spin spaces \( M \) with the following structure. We shall assume that \( M \) is a nilpotent Lie group on \( \mathbb{R}^n \) with a Hörmander system \( X^1, \ldots, X^N, N \leq n \), of smooth vector fields \( X^k = \sum_{j=1}^n a_{kj} \frac{\partial}{\partial x_j} \), \( k = 1, \ldots, N \), i.e. \( a_{kj} \) are smooth functions of \( x \in \mathbb{R}^n \). The (sub)gradient \( \nabla \) with respect to this structure is
the vector operator $\nabla f = (X^1 f, \ldots, X^N f)$. We consider
\[
\| \nabla f \|_2 := (X^1 f)^2 + \cdots + (X^N f)^2
\]
When these operators refer to a spin space $M^i$ at a node $i \in \mathbb{Z}^d$ this will be indicated by an index $\nabla_i f = (X^1_i f, \ldots, X^N_i f)$. For a subset $\Lambda$ of $\mathbb{Z}^d$ we define $\nabla_\Lambda := (\nabla_i, i \in \Lambda)$ and
\[
\| \nabla_\Lambda f \|_2 := \sum_{i \in \Lambda} \| \nabla_i f \|_2
\]
The spin space $M$ is equipped with a metric $d(x, y)$ for $x, y \in M$. For example, in the case of $M$ being a Euclidean space then $d$ is the Euclidean metric or if $M$ is the Heisenberg group, then $d$ is the Carnot-Carathéodory metric. We will consider examples and applications of the main theorem for both. In all cases, for $x \in M$ we will conventionally write $d(x)$ for the distance of $x$ from 0
\[
d(x) := d(x, 0)
\]
where 0 is a specific point of $M$, for example the origin if $M$ is $\mathbb{R}^n$ or the identity element of the group when $M$ is a Lie group. Furthermore, we assume that there exists a $k_0 > 0$ such that $\| \nabla d \| \leq k_0$. For instance, in the Euclidean and the Carnot-Carathéodory metrics $k_0 = 1$.

A spin at a site $i \in \mathbb{Z}^d$ of a configuration $\omega \in \Omega$ will be indicated by an index, i.e. we will write $\omega_i$. This takes values in $M^i$ which is an identical copy of the spin space $M$. For a subset $\Lambda \subset \mathbb{Z}^d$ we will identify $M^\Lambda$ with the Cartesian product of the $M^i$ for every $i \in \Lambda$.

The spin space $M$ is equipped with a natural measure. For example, when $M$ is a group then we assume that the measure is one which is invariant under the group operation, for which we write $dx$. Again, for any $i \in \mathbb{Z}^d$, we use a subscript to indicate the natural measure $dx_i$ on $M^i$. In the case of a Euclidean space or the Heisenberg group for instance, this is the Lebesgue measure. For the product measure derived from the $dx_i$, $i \in \Lambda$ we will write $dx_\Lambda := \otimes_{i \in \Lambda} dx_i$. The measures of the local specification $\{E^{\Lambda, \omega}\}$ for $\Lambda \subset \mathbb{Z}^d$ and $\omega \in M^{\partial \Lambda}$, are defined as
\[
E^{\Lambda, \omega}(dx_\Lambda) = \frac{1}{Z^{\Lambda, \omega}} e^{-H^{\Lambda, \omega}(x_\Lambda)} dx_\Lambda,
\]
where $Z^{\Lambda, \omega}$ is a normalization constant. The Hamiltonian function $H^{\Lambda, \omega}$ has the form
\[
H^{\Lambda, \omega}(x_\Lambda) := \sum_{i \in \Lambda} \phi(x_i) + \sum_{i, j \in \Lambda, j \sim i} J_{ij} V(x_i, x_j) + \sum_{i \in \Lambda, j \in \partial \Lambda, j \sim i} J_{ij} V(x_i, \omega_j),
\]
We call $\phi$ the phase and $V$ the interaction. In this work we consider exclusively quadratic interactions $V$, i.e.
\[
|V(x_i, \omega_j)| \leq kd^2(x_i) + kd^2(\omega_j)
\]
and
\[
\| \nabla_i V(x_i, \omega_j) \|^2 \leq kd^2(x_i) + kd^2(\omega_j)
\]
for some $k \geq 1$. We will assume that there exists a $J$ such that $|J_{ij}| \leq J$ and that $J_{ij} V(x_i, x_j) \geq 0$. 

For a function \( f \) from \( \mathbb{M}^{d} \) into \( \mathbb{R} \), we will conventionally write \( \mathbb{E}^{\Lambda, \omega} f \) for the expectation of \( f \) with respect to \( \mathbb{E}^{\Lambda, \omega} \). For economy we will frequently omit the boundary conditions and we will write \( \mathbb{E}^{\Lambda} f \) instead of \( \mathbb{E}^{\Lambda, \omega} \).

The measures of the local specification obey the Markov property
\[
\mathbb{E}^{\Lambda} \mathbb{E}^{K} f = \mathbb{E}^{\Lambda} f, \quad K \subset \Lambda.
\]

We say that the probability measure \( \nu \) on \( \mathbb{M}^{\mathbb{Z}^{d}} \) is an infinite volume Gibbs measure for the local specifications \( \{ \mathbb{E}^{\Lambda, \omega} \} \) if it satisfies the Dobrushin-Lanford-Ruelle equation:
\[
\nu \mathbb{E}^{\Lambda} f = \nu, \quad \Lambda \supset \mathbb{Z}^{d},
\]
We refer to [Pr], [B-HK] and [D] for details. Throughout the paper we shall assume that we are in the case where \( \nu \) exists (uniqueness will be deduced from our results, see Proposition 7.2). Furthermore, we will consider functions \( f : \mathbb{M}^{\mathbb{Z}^{d}} \to \mathbb{R} \) such that \( fd \in L^{2}(\nu) \).

The main interest of the paper is the logarithmic Sobolev inequality. We say that a probability measure \( \mu \) in \( \mathbb{M}^{s} \) satisfies the logarithmic Sobolev inequality, if there exists a constant \( c > 0 \) such that
\[
\mu \left( f^{2} \log \frac{f^{2}}{\mu(f^{2})} \right) \leq c \mu \| \nabla f \|^{2}
\]
We notice two important properties for the log-Sobolev inequality. The first is that it implies the spectral gap inequalities, that is, there exists a constant \( c' < c \) such that
\[
\mu \| f - \mu f \|^{2} \leq c' \mu \| \nabla f \|^{2}
\]
The second is that both the log-Sobolev inequality and the spectral gap inequality are retained under product measures. Proofs of these two assertions can be found in Gross [G], Guionnet and Zegarlinski [G-Z] and Bobkov and Zegarlinski [B-Z].

Under the spin system framework the log-Sobolev inequality for the local specification \( \{ \mathbb{E}^{\Lambda, \omega} \} \) takes the form
\[
\mathbb{E}^{\Lambda, \omega} \left( f^{2} \log \frac{f^{2}}{\mathbb{E}^{\Lambda, \omega} f^{2}} \right) \leq c \mathbb{E}^{\Lambda, \omega} \| \nabla f \|^{2}
\]
where the constant \( c \) is now required uniformly on the subset \( \Lambda \) and the boundary conditions \( \omega \in \partial \Lambda \). In the special case where \( \Lambda = \{ i \} \) then the constant is considered uniformly on the boundary conditions \( \omega \in \{ \sim i \} \). The analogue log-Sobolev inequality for the infinite volume Gibbs measure \( \nu \) is then defined as
\[
\nu \left( f^{2} \log \frac{f^{2}}{\nu f^{2}} \right) \leq c \nu \| \nabla_{\mathbb{Z}^{d}} f \|^{2}
\]
The aim of this paper is to show that the infinite volume Gibbs measure \( \nu \) satisfies the log-Sobolev inequality (2.4) for an appropriate constant. As explained in the introduction, in the case of quadratic interactions, previous works concentrated in proving first the stronger (2.3) for all \( \Lambda \subset \mathbb{Z}^{d} \), or assumed the log-Sobolev inequality (2.3) for the one site \( \Lambda = i \) and then derived from these (2.4).

Our aim is to show that if we assume the weaker inequality (2.2) for the phase measure \( \mu(dx) = \frac{e^{-\phi(x)}dx}{\int e^{-\phi(x)}dx} \), then in the presence of quadratic interaction this is sufficient to obtain directly the log-Sobolev inequality for the Gibbs measure (2.4), without the need
Assume or prove any of the stronger inequalities (2.3) that require uniformity on the boundary conditions and/or the dimension of the measure.

The first result of the paper follows:

**Theorem 2.1.** Assume that the measure \(\mu(dx) = \frac{e^{-\phi(x)}dx}{\int e^{-\phi(x)}dx}\) in \(M\) satisfies the log-Sobolev inequality and that the local specification \(\{E_{\Lambda,\omega}\}\) has quadratic interactions \(V\) as in (2.1). Then for \(J\) sufficiently small the infinite dimensional Gibbs measure in \(M^{\mathbb{Z}^d}\) satisfies a log-Sobolev inequality.

Since the main hypothesis of the theorem refers just to the measure \(\mu(dx) = \frac{e^{-\phi(x)}dx}{\int e^{-\phi(x)}dx}\) satisfying a logarithmic Sobolev inequality, we can take all the probability measures from \(\mathbb{R}^n\) that satisfy a log-Sobolev inequality and get measures on the statistical mechanics framework of spin systems on the lattice \(\mathbb{Z}^d\) just by adding quadratic interactions as described in (2.1).

From the plethora of theorems and criteria that have been developed for the Euclidean \(\mathbb{R}^n\) for \(n \geq 1\), among others in [B-L], [B], [B-E], [B-G], and [B-Z] one can generalise these to the spin system framework just by applying them to the phase \(\phi\) and then add quadratic interactions \(V\). As a typical example, one can then for instance obtain for then Euclidean space \(n \geq 1\) with \(d\) the Euclidian metric, \(X_i = \frac{\partial}{\partial x_i}\) and \(dx_i\) the Lebesgue measure, the following example of measures: Consider the phase \(\phi(c) = \|x\|^p\) for any \(p \geq 2\) and interactions \(V(x,y) = \|x - y\|^2_2\). Then the associated Gibbs measure satisfies a logarithmic Sobolev inequality.

Furthermore, as will be described in Theorem 2.2 that follows, with additional assumptions on the distance and the gradient we can obtain results comparable to the once obtained in [H-Z] for general metric spaces. We consider general \(n\)-dimensional non-compact metric spaces. For the distance \(d\) and the (sub)gradient \(\nabla\), in addition to the hypothesis of Theorem 2.1 we assume that

\[(D1) : \frac{1}{\sigma} < |\nabla d| \leq 1\]

for some \(\sigma \in [1, \infty)\), and

\[(D2) : \Delta d \leq K\]

outside the unit ball \(\{d(x) < 1\}\) for some \(K \in (0, +\infty)\). We also assume that the gradient \(\nabla\) satisfies the integration by parts formula. In the case of \(\nabla f = (X^1f, \ldots, X^Nf)\) with vector fields \(X^k = \sum_{j=1}^n a_{kj} \frac{\partial}{\partial x_j}\) it suffices to request that \(a_{kj}\) is a function of \(x \in \mathbb{R}^d\) not depending on the \(j\)-th coordinate \(x_j\).

If \(dx\) is the \(n\)-dimensional Lesbegue measure we assume that it satisfies the Classical-Sobolev inequality (C-S)

\[
\left(\int |f|^{2+\epsilon}dx\right)^{\frac{2}{2+\epsilon}} \leq \alpha \int \|\nabla f\|^2dx + \beta \int |f|^2dx
\]

for positive constants \(\alpha, \beta\), as well as the Poincaré inequality on the ball \(B_R\), that is there exists a constant \(c_R \in (0, \infty)\) such that

\[
\frac{1}{|B_R|} \int_{B_R} f - \frac{1}{|B_R|} \int_{B_R} f \leq c_R \frac{1}{|B_R|} \int_{B_R} \|\nabla f\|^2dx
\]

(L-P)
The Classical Sobolev inequality (C-S) is for instance satisfied in the case of the $\mathbb{R}^n$, $n \geq 1$ with $d$ being the Euclidean distance, as well as for the case of the Heisenberg group, with $d$ being the Carnot-Carathéodory distance. The Poincaré inequality on the ball for the Lebesgue measure (L-P) is a standard result for $n \geq 3$ (see for instance [H], [H-Z], [D] and [V-SC-C]), while for $n = 1, 2$ one can look on [Pa2]. Under this framework, if we combine our main result Theorem 2.1, together with Corollary 3.1 and Theorem 4.1 from [H-Z] we obtain the following theorem

**Theorem 2.2.** Assume distance $d$ and the (sub)gradient $\nabla$ are such that (D1)-(D2) as well as (C-S) and (L-P) are satisfied. Let a probability measure $\mu(dx) = e^{-\phi(x)}e^{-\phi(x)}dx$, where $dx$ the Lebesgue measure, such that

$$\phi(x) = W(x) + B(x)$$

defined with a differential potential $W$ satisfying

$$\|\nabla W\|^q \leq \delta d^p + \gamma$$

with $p \geq 2$ and $q$ the conjugate of $p$, and suppose that $B$ is a measurable function such that $\text{osc}(B) = \max B - \min B < \infty$. Assume that the local specification $\{E_\Lambda^\omega\}$ has quadratic interactions $V$ as in (2.1). Then for $J$ sufficiently small the infinite dimensional Gibbs measure satisfies a log-Sobolev inequality.

An interesting application of the last theorem is the special case of the Heisenberg group, $\mathbb{H}$. This can be described as $\mathbb{R}^3$ with the following group operation:

$$x \cdot \tilde{x} = (x_1, x_2, x_3) \cdot (\tilde{x}_1, \tilde{x}_2, \tilde{x}_3) = (x_1 + \tilde{x}_1, x_2 + \tilde{x}_2, x_3 + \tilde{x}_3 + \frac{1}{2}(x_1\tilde{x}_2 - x_2\tilde{x}_1))$$

$\mathbb{H}$ is a Lie group, and its Lie algebra $\mathfrak{h}$ can be identified with the space of left invariant vector fields on $\mathbb{H}$ in the standard way. The vector fields

$$X_1 = \partial_{x_1} - \frac{1}{2}x_2\partial_{x_3}$$
$$X_2 = \partial_{x_2} + \frac{1}{2}x_1\partial_{x_3}$$
$$X_3 = \partial_{x_3} = [X_1, X_2]$$

form a Jacobian basis, where $\partial_{x_i}$ denoted derivation with respect to $x_i$. From this it is clear that $X_1, X_2$ satisfy the Hörmander condition (i.e., $X_1, X_2$ and their commutator $[X_1, X_2]$ span the tangent space at every point of $\mathbb{H}_1$). The sub-gradient is given by

$$\nabla := (X_1, X_2)$$

For more details one can look at [B-L-U]. In [I-P], a first example of a measure on the Heisenberg group with a Gibbs measure that satisfies a logarithmic Sobolev inequality was presented. Here, with the use of Theorem 2.2 we can obtain examples with a phase $\phi$ that is nowhere convex and include more natural quadratic interactions. Such an example, that satisfies the conditions of Theorem 2.2 with a phase that goes beyond convexity at infinity is the following:

$$\phi(x) = d^p(x) + \cos(d(x))d^{p-1}(x)$$
and
\[ V(x, y) = d^2(x \cdot y^{-1}) \]
where \( \cdot \) the group operation and \( y^{-1} \) the inverse in respect to this operation.

The proof of Theorem 2.1 is divided into two parts presented on the next two propositions 2.3 and 2.4. In the first one, we prove a weaker assertion, that the claim of Theorem 2.1 is true under the conditions of Theorem 2.1 together with the U-bound inequality (2.5).

**Proposition 2.3.** Assume that the measure \( \mu(dx) = \frac{e^{-\phi(x)}dx}{\int e^{-\phi(x)}dx} \) satisfies the log-Sobolev inequality and that the local specification \( \{ \mathcal{E}^{\Lambda, \omega} \} \) has quadratic interactions \( V \) as in (2.1). Furthermore, assume that there exists a \( C \geq 1 \) such that the following U-bound inequality is satisfied
\[
\rho(d^2(x_k)f^2) \leq C \nu(f^2) + C \sum_{n=0}^{\infty} J^n \sum_{j: \text{dist}(j,k) = n} \nu(\|\nabla_j f\|^2)
\]
Then for \( J \) sufficiently small the infinite dimensional Gibbs measure satisfies the log-Sobolev inequality.

The proof of this proposition will be presented in section 7.1. Then Theorem 2.1 follows from Proposition 2.3 and the next proposition which states that the conditions of Theorem 2.1 imply the U-bound inequality (2.5) of Proposition 2.3.

**Proposition 2.4.** Assume that the measure \( \mu(dx) = \frac{e^{-\phi(x)}dx}{\int e^{-\phi(x)}dx} \) satisfies the log-Sobolev inequality and that the local specification \( \{ \mathcal{E}^{\Lambda, \omega} \} \) has quadratic interactions \( V \) as in (2.1). Then for \( J \) sufficiently small the Gibbs measure satisfies the U-bound inequality (2.5).

A few words about the structure of the paper. Since the proof of the main result presented in Theorem 2.1 trivially follows from Proposition 2.3 and Proposition 2.4, we concentrate on showing the validity of these two.

For simplicity we will present the proof for the 2-dimensional lattice \( \mathbb{Z}^2 \). At first, the proof of Proposition 2.4 will be presented in section 3 where the U-bound inequality (2.5) is shown to hold under the conditions of the main theorem. The proof of Proposition 2.3 will occupy the rest of the paper. In particular, in section 4 a Sweeping Out inequality will be shown as well as a spectral gap type inequality for the one site measure. In section 5 a second Sweeping Out inequality is proven. In section 6 logarithmic Sobolev type inequalities for the one site measure as well as for the infinite product measure are proven. Then in the section 7 we present a spectral gap type inequality for the product measure directly from the log-Sobolev inequality shown in the previous section. Using this we show convergence to the Gibbs measure as well as it’s uniqueness. Then at the final part of the section, in subsection 7.1, we put all the previous bits together to prove Proposition 2.3.

3. PROOF OF THE U-BOUND INEQUALITY

U-bound inequalities where introduced in [H-Z] in order to prove q logarithmic Sobolev inequalities. In this work we use U-bound inequalities in order to control the quadratic interactions. In this section we prove Proposition 2.4 that states that if the measure
\[ \mu(dx) = \frac{e^{-\phi(x)}}{\int e^{-\phi(x')}dx'} \] satisfies the log-Sobolev inequality and the local specification has quadratic interactions then the U-bound inequality \((2.5)\) is satisfied.

**Lemma 3.1.** If \( \mu \) satisfies the log-Sobolev inequality and the local specification has quadratic interactions \( V \) as in \((2.4)\), then for any \( i \in \mathbb{Z}^2 \)

\[ \nu(d^2(x_i)f^2) \leq K_0 \nu(f^2) + K_0 \nu(\|\nabla_i f\|^2) + K_1 J^2 \sum_{j \sim i} \nu(f^2 d^2(\omega_j)) \tag{3.1} \]

for positive constants \( K_0 \) and \( K_1 \).

**Proof.** If we use the following entropic inequality (see \[D-S\])

\[ \forall t > 0, \quad \pi(uv) \leq \frac{1}{t} \log(\pi(e^{tu})) + \frac{1}{t} \pi(v \log v) \tag{3.2} \]

for any probability measure \( \pi \) and \( v \geq 0, \pi v = 1 \), we get

\[ \mu(d^2(x_i)f^2) \leq \frac{1}{t} \mu(f^2) \log \left( \mu(e^{td^2(x_i)}) \right) \]

For the first term on the right hand side of \((3.3)\) we can use Theorem 4.5 from \[H-Z\] (see also \[A-S\]) which states that when a measure \( \mu \) satisfies the log-Sobolev inequality then for any function \( g \) such that

\[ \|\nabla g\|^2 \leq a g + b \]

for \( a, b \in (0, \infty) \) we have

\[ \mu e^{tg} < \infty \]

for all \( t \) sufficiently small. Since

\[ \|\nabla(d^2)\|^2 \leq 4d^2 \|\nabla d\|^2 \leq 4k_0^2 d^2 \]

from our hypothesis on \( d \) : \( \|\nabla d\| \leq k_0 \), we obtain that for \( t \) sufficiently small

\[ \log \left( \mu(e^{td^2(x_i)}) \right) \]

for some \( K \). From this and the fact that \( \mu \) satisfies the log-Sobolev inequality \((2.2)\) with some constant \( c \), \((3.3)\) becomes

\[ \mu(d^2(x_i)f^2) \leq \frac{K}{t} \mu(f^2) + \frac{c}{t} \mu(\|\nabla_i f\|^2) \]

If we substitute \( f \) by \( f e^{-\frac{V_i}{2}} \), where we denoted \( V^i = \sum_{j \sim i} J_{ij} V(x_i, \omega_j) \), we get

\[ \int e^{-H^{i,\omega}} d^2(x_i) f^2 dx_i \leq \frac{K}{t} \int e^{-H^{i,\omega}} f^2 dx_i + \frac{c}{t} \mu(\|\nabla_i (f e^{-\frac{V_i}{2}})\|^2) \tag{3.4} \]

For the second term of the right hand side of \((3.4)\) we have

\[ \mu(\|\nabla_i (f e^{-\frac{V_i}{2}})\|^2) \leq 2 \int e^{-H^{i,\omega}} \|\nabla_i f\|^2 dx_i + \frac{1}{2} \int e^{-H^{i,\omega}} f^2 \|\nabla_i V^i\|^2 dx_i \]

If we substitute this on \((3.4)\) and divide both parts with \( Z^{i,\omega} \) we will get

\[ \mathbb{E}^{i,\omega}(d^2(x_i)f^2) \leq \frac{K}{t} \mathbb{E}^{i,\omega}(f^2) + \frac{2c}{t} \mathbb{E}^{i,\omega}(\|\nabla_i f\|^2) + \frac{c}{2t} \mathbb{E}^{i,\omega}(f^2 \|\nabla_i V^i\|^2) \]
If we take the expectation with respect to the Gibbs measure we obtain
\[ \nu(d^2(x_i)f^2) \leq \frac{K}{t} \nu(f^2) + \frac{2c}{t} \nu(\|\nabla_i f\|^2) + \frac{c}{2t} \nu(f^2 \|\nabla_i V\|^2) \]
From our main assumption (2.1) about the interactions, \( \|\nabla_i V(x_i, \omega_j)\|^2 \leq kd^2(x_i) + kd^2(\omega_i) \), we have that
\[ \|\nabla_i V\|^2 \leq 16k^2f^2d^2(x_i) + 4k^2f^2 \sum_{j \sim i} d^2(\omega_j) \]
which leads to
\[ \nu(d^2(x_i)f^2) \leq \frac{K}{t} \nu(f^2) + \frac{2c}{t} \nu(\|\nabla_i f\|^2) + 8ck^2J^2 \frac{d^2(x_i)}{t} + 4ck^2J^2 \frac{\sum_{j \sim i} d^2(\omega_j)}{t} \]
for \( J \) sufficiently small so that \( \frac{8ck^2J^2}{t} < 1 \) and
\[ \frac{2ck^2J^2}{t} + 24c^2k^4J^4 \frac{\|\nabla_i f\|^2}{t} \leq \frac{3ck^2J^2}{t} \frac{d^2(x_i)}{t} \]
we obtain
\[ \nu(d^2(x_i)f^2) \leq \frac{K}{(1 - \frac{8ck^2J^2}{t})t} \nu(f^2) + \frac{2c}{(1 - \frac{8ck^2J^2}{t})t} \nu(\|\nabla_i f\|^2) + \frac{3ck^2J^2}{t} \frac{\sum_{j \sim i} \nu(f^2 d^2(\omega_j))}{t} \]
and the lemma follows for appropriate constants \( K_0 \) and \( K_1 \).

**Lemma 3.2.** If for any \( i \in \mathbb{Z}^2 \)
\[ P(i) \leq R(i) + bs^2 \sum_{j \sim i} P(j) \]  
for some \( b > 0 \) and some \( s \in (0, 1) \) sufficiently small, and
\[ \lim_{n \to \infty} (s^n \sum_{\text{dist}(j,k)=n} P(k)) = 0 \quad \forall k \in \mathbb{Z}^2 \]
then
\[ P(k) \leq \frac{1}{1 - bs} \sum_{n=0}^{\infty} \left( s^n \sum_{j: \text{dist}(j,k)=n} R(j) \right) \]
for any \( k \in \mathbb{Z}^2 \).

**Proof.** We will first show that for any \( n \in \mathbb{N} \) there exists an \( s \in (0, 1) \) such that
\[ \sum_{\text{dist}(j,k)=n} P(j) \leq \frac{1}{1 - 3bs^2} \sum_{\text{dist}(j,k)=n} R(j) + \sum_{t=0}^{n-1} s^{n-t} \sum_{\text{dist}(j,k)=t} R(j) + s \sum_{\text{dist}(j,k)=n+1} P(j) \]
We will work by induction.

Step 1: The base step of the induction \((n = 1)\). From (3.5) we have

\[
\sum_{\text{dist}(t,k)=1} P(t) \leq \sum_{\text{dist}(t,k)=1} R(t) + bs^2 \sum_{\text{dist}(t,k)=1} \sum_{i \sim t} P(i) \leq \sum_{\text{dist}(t,k)=1} R(t) +
\]
\[
+ 2bs^2 \sum_{\text{dist}(t,k)=2} P(t) + 4bs^2 P(k)
\]

If we use again (3.5) to bound the last term we obtain

\[
\sum_{\text{dist}(t,k)=1} P(t) \leq \sum_{\text{dist}(t,k)=1} R(t) + 2bs^2 \sum_{\text{dist}(t,k)=2} P(t)
\]
\[
+ 4b^2 s^4 \sum_{\text{dist}(t,k)=1} P(t) + 4bs^2 R(k)
\]

For \(s\) small enough so that \(4b^2 s^4 < 1, 4bs^2 \leq 3\) and \(4bs^2 + 4b^2 s^5 < s\) we have

\[
\sum_{\text{dist}(t,k)=1} P(t) \leq \frac{1}{1 - 4b^2 s^4} \sum_{\text{dist}(t,k)=1} R(t) + \frac{2bs^2}{1 - 4b^2 s^4} \sum_{\text{dist}(t,k)=2} P(t)
\]
\[
+ \frac{4b^2 s^4}{1 - 4b^2 s^4} R(k)
\]
\[
\leq \frac{1}{1 - 3bs^2} \sum_{\text{dist}(t,k)=1} R(t) + s \sum_{\text{dist}(t,k)=2} P(t)
\]
\[
+ sR(k)
\]

since \(4b^2 \leq 3 \Rightarrow \frac{1}{1 - 4b^2 s^4} \leq \frac{1}{1 - 3bs^2}\) and \(4b^2 + 4b^2 s^5 < s \Rightarrow \frac{4bs^2}{1 - 4b^2 s^4} \leq s\). This proves the base step.

Step 2: The induction step. We assume that (3.7) holds true for some \(n \geq 2\), and we will show that it also holds for \(n + 1\), that is

\[
(3.8) \quad \sum_{\text{dist}(j,k)=n+1} P(j) \leq \frac{1}{1 - 3bs^2} \sum_{\text{dist}(j,k)=n+1} R(j) + s^{n+1-t} \sum_{\text{dist}(j,k)=t} P(j) + \sum_{\text{dist}(j,k)=n+2} P(j)
\]

To bound the left hand side of (3.8) we can use again (3.5)

\[
\sum_{\text{dist}(j,k)=n+1} P(j) \leq \sum_{\text{dist}(j,k)=n+1} R(j) + bs^2 \sum_{\text{dist}(j,k)=n+1} \sum_{l \sim j} P(l) \leq
\]
\[
\sum_{\text{dist}(j,k)=n+1} R(j) + 3bs^2 \sum_{\text{dist}(j,k)=n} P(j) + 2bs^2 \sum_{\text{dist}(j,k)=n+2} P(j)
\]
If we bound \( \sum_{\text{dist}(j,k)=n} P(j) \) by (3.7) we get
\[
\sum_{\text{dist}(j,k)=n+1} P(j) \leq \sum_{\text{dist}(j,k)=n+1} R(j) + \frac{3bs^2}{1-3bs^2} \sum_{\text{dist}(j,k)=n} R(j) +
3bs^2 \sum_{t=0}^{n-1} s^{n-t} \sum_{\text{dist}(j,k)=t} R(j) +
3bs^3 \sum_{\text{dist}(j,k)=n+1} P(j) + 2bs^2 \sum_{\text{dist}(j,k)=n+2} P(j)
\]

For \( s \) small enough such that \( 3bs^2 < 1 \), \( \frac{3bs^2}{1-3bs^2} s \leq s \) and \( 3b(s^2 + s^3 + s^4) \leq 9b^2 s^6 + s \Rightarrow \frac{3bs^2}{1-3bs^2} s \leq s \) we obtain
\[
\sum_{\text{dist}(j,k)=n+1} P(j) \leq \frac{1}{1-3bs^2} \sum_{\text{dist}(j,k)=n+1} R(j) + \sum_{t=0}^{n} s^{n+1-t} \sum_{\text{dist}(j,k)=t} R(j) +
+ s \sum_{\text{dist}(j,k)=n+2} P(t)
\]
which finishes the proof of (3.7).

We can now complete the proof of the lemma. At first we can bound the second term on the right hand side of (3.5) by (3.7). That gives
\[
P(k) \leq (1 + bs^3) R(k) + \frac{bs^2}{1-3bs^2} \sum_{j: \text{dist}(j,k)=1} R(j) + bs^3 \sum_{\text{dist}(j,k)=2} P(j) \leq
(1 + bs^3) R(k) + s \sum_{j: \text{dist}(j,k)=1} R(j) + bs^3 \sum_{\text{dist}(j,k)=2} P(j)
\]
for \( s \) sufficiently small so that \( \frac{bs^2}{1-3bs^2} s \leq s \). If we use again (3.7) to bound the third term on the right hand we have
\[
P(k) \leq (1 + bs^3) R(k) + s \sum_{j: \text{dist}(j,k)=1} R(j) + s^2 \sum_{\text{dist}(j,k)=2} R(j) +
bs^4 \sum_{t=0}^{1} s^{5-t} \sum_{\text{dist}(j,k)=t} R(j) + bs^4 \sum_{\text{dist}(j,k)=3} P(j)
\]
where above we used once more that \( \frac{bs^2}{1-3bs^2} s \leq s \). If we rearrange the terms we have
\[
P(k) \leq (1 + bs^3) R(k) + (s + bs^4) \sum_{j: \text{dist}(j,k)=1} R(j) + s^2 \sum_{\text{dist}(j,k)=2} R(j) +
bs^4 \sum_{\text{dist}(j,k)=3} P(j)
\]
If we continue inductively to bound the right hand side by (3.7) and take under account (3.6), then for $s$ sufficiently small such that $sb < 1$ we obtain

$$P(k) \leq \left( \sum_{r=0}^{\infty} (bs)^r \right) \sum_{n=0}^{\infty} \left( s^n \sum_{j: \text{dist}(j,k)=n} R(j) \right)$$

which proves the lemma.

We now prove the U-bound inequality of Proposition 2.4.

3.1. proof of Proposition 2.4.

Proof. The proof of the proposition follows directly from Lemma 3.1 and Lemma 3.2. If one considers $P(k) := \nu(d^2(x_k)f^2)$ and $R(k) := K_0 \nu(f^2) + K_0 \nu(\|\nabla f\|^2)$ then from (3.1) of Lemma 3.1 we see that condition (3.5) is satisfied for $b := K_1 = \frac{2eb^2}{e}$ and $s = J$. Furthermore, since by our hypothesis $\nu(d^2(x_i)f^2) \leq M < \infty$ for some positive $M$ uniformly on $i$ and $\{\#j: \text{dist}(j,k) = n\} \leq 4^n$, we can choose $J$ sufficiently small so that for $s = J < \frac{1}{4}$ condition (3.6) of Lemma 3.2 to be also satisfied:

$$\lim_{n \to \infty} (s^n \sum_{\text{dist}(j,k)=n} P(k)) \leq M \lim_{n \to \infty} (4s)^n = 0 \quad \forall k \in \mathbb{Z}^2$$

Since (3.5) and (3.6) are satisfied we can apply Lemma 3.2. We then obtain

$$\nu(d^2(x_k)f^2) \leq \frac{1}{1 - K_1J} \sum_{n=0}^{\infty} \left( J^n \sum_{j: \text{dist}(j,k)=n} (K_0 \nu(f^2) + K_0 \nu(\|\nabla f\|^2)) \right) \leq \frac{K_0}{1 - K_1J} \left( \sum_{n=0}^{\infty} (4J)^n \nu(f^2) + \sum_{n=0}^{\infty} J^n \sum_{j: \text{dist}(j,k)=n} \nu(\|\nabla f\|^2) \right)$$

For $J$ small enough so that $4J < 1$ we get

$$\nu(d^2(x_k)f^2) \leq \frac{K_0}{(1 - K_1J)(1 - 4J)} \nu(f^2) + \frac{K_0}{1 - K_1J} \sum_{n=0}^{\infty} J^n \sum_{j: \text{dist}(j,k)=n} \nu(\|\nabla f\|^2)$$

which proves the proposition.

4. First Sweeping Out Inequality.

Sweeping out inequalities for the local specification were introduced in [Z1], [Z2] and [G-Z] to prove logarithmic Sobolev inequalities. Here we prove a weaker version of them for the Gibbs measure, similar to the ones used in [Pa1] and [Pa3], where however, interactions higher than quadratic were considered.

Lemma 4.1. Assume that the measure $\mu$ satisfies the log-Sobolev inequality and that the local specification has quadratic interactions $V$ as in (2.1). Then, for $J$ sufficiently
small, for every $j \sim i$

$$\nu \|\nabla_j (E^i f)\|^2 \leq D_1 \nu \|\nabla_j f\|^2 + D_2 J^2 \nu E^i (f - E^i f)^2 + J D_1 \sum_{n=1}^{\infty} J^n \sum_{\text{dist}(r,i)=n} \nu (\|\nabla_r f\|^2)$$

for some constant $D_1 \in [1, \infty)$.

**Proof.** Consider the (sub)gradient $\nabla_j = (X_j^1, X_j^2, ..., X_j^N)$. We can then write

$$\|\nabla_j (E^i f)\|^2 = \sum_{k=1}^{N} (X_j^k (E^i f))^2 \tag{4.1}$$

If we denote $\rho_i = \frac{e^{-H(x_i)}}{\int e^{-H(x_i)} dx}$ the density of the measure $E^i$, then for every $k = 1, ..., N$ we have

$$(X_j^k (E^i f))^2 \leq \left| X_j^k \left( \int \rho_i f dx \right) \right|^2 \leq$$

$$2 \left( \int (X_j^k f) \rho_i dx \right)^2 + 2 \left( \int f (X_j^k \rho_i) dx \right)^2 \tag{4.2}$$

$$2 \left| E^i (X_j^k f) \right|^2 + 2 J^2 \left| E^i (f, X_j^k V(x_j, x_i)) \right|^2 \tag{4.3}$$

where in (4.3) we bounded the coefficients $J_{i,j}$ by $J$ and we have denoted $E^i(f; g)$ the covariance of $f$ and $g$. If we take expectations with respect to the Gibbs measure $\nu$ and use the Hölder inequality in both terms of (4.3) we obtain

$$\nu \left| X_j^k (E^i f) \right|^2 \leq 2 \nu (X_j^k f)^2 + 2 J^2 \nu E^i ((f - E^i f)^2 (X_j^k V(x_j, x_i))^2)$$

If we take the sum over all $k$ from 1 to $N$ in the last inequality and take under account (4.1) we get

$$\|\nabla_j (E^i f)\|^2 \leq 2 \nu \|\nabla_j f\|^2 + 2 J^2 \nu E^i ((f - E^i f)^2 (X_j^k V(x_j, x_i))^2)$$

where above we used that the interactions are quadratic as in hypothesis (2.1). This leads to

$$\nu \|\nabla_j (E^i f)\|^2 \leq 2 \nu \|\nabla_j f\|^2 + k 2 J^2 \nu (f - E^i f)^2 + k 2 J^2 \nu ((f - E^i f)^2 d^2(x_i)) + k 2 J^2 \nu ((f - E^i f)^2 d^2(x_j)) \tag{4.4}$$
In order to bound the third term on the right hand side of (4.4) we can use Proposition 2.4

\[ \nu((f - E^i f)^2 d^2(x_i)) \leq C \nu(f - E^i f)^2 + C \sum_{n=0}^{\infty} J^n \sum_{k: \text{dist}(k,i)=n} \nu(\|\nabla_k(f - E^i f)\|^2) \leq \\
C \nu(f - E^i f)^2 + 2C \sum_{n=0}^{\infty} J^n \sum_{k: \text{dist}(k,i)=n} \nu(\|\nabla_k f\|^2) + \\
2C \sum_{n=0}^{\infty} J^n \sum_{k: \text{dist}(k,i)=n} \nu(\|\nabla_k(E^i f)\|^2) \]

Since \( \nabla_k(E^i f) = E^i(\nabla_k f) \) when \( \text{dist}(k,i) > 1 \) and \( \nabla_i(E^i f) = 0 \) the last inequality takes the form

\[ (4.5) \quad \nu((f - E^i f)^2 d^2(x_i)) \leq C \nu(f - E^i f)^2 + 2C \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,i)=n} \nu(\|\nabla_r f\|^2) + \\
2CJ \sum_{j \sim i} \nu(\|\nabla_j(E^i f)\|^2) \]

For the fourth term on the right hand side of (4.4) we can use again Proposition 2.4

\[ \nu((f - E^i f)^2 d^2(x_i)) \leq C \nu(f - E^i f)^2 + C \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,j)=n} \nu(\|\nabla_r(f - E^i f)\|^2) \leq \\
C \nu(f - E^i f)^2 + 2C \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,j)=n} \nu(\|\nabla_r f\|^2) + \\
2C \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,j)=n} \nu(\|\nabla_r(E^i f)\|^2) \]

But \( \nabla_r(E^i f) = E^i(\nabla_r f) \) when \( \text{dist}(r,i) > 1 \) and \( \nabla_i(E^i f) = 0 \). Furthermore, since \( j \sim i \) when \( \text{dist}(r,j) = n \), the \( r \)'s that neighbour \( i \) will have distance from \( j \) equal to 2 when \( r \neq j \) or 0 when \( r = j \). So (4.6) becomes

\[ (4.7) \quad \nu((f - E^i f)^2 d^2(x_j)) \leq C \nu E^i f - E^i f)^2 + 2C \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,j)=n} \nu(\|\nabla_r f\|^2) + \\
2CJ^2 \sum_{r \sim i; r \neq j} \nu(\|\nabla_r(E^i f)\|^2) \]

If we combine together (4.4), (4.5) and (4.7) we get

\[ \nu(\|\nabla_j(E^i f)\|^2) \leq (2 + 16kCJ^2) \nu(\|\nabla_j f\|^2) + (1 + 2C) 2kJ^2 \nu(f - E^i f)^2 + \\
(4.8) \quad 8kCJ \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,i)=n} \nu(\|\nabla_r f\|^2) + 8kJ^2 C \sum_{r \sim i} \nu(\|\nabla_r(E^i f)\|^2) \]
since \( J^2 < J \) and

\[
(4.9) \quad \sum_{n=0}^{\infty} J^{n+1} \sum_{r: \text{dist}(r,j)=n} \nu \| \nabla r f \| ^2 \leq \sum_{n=0}^{\infty} J^{n} \sum_{r: \text{dist}(r,i)=n} \nu \| \nabla r f \| ^2
\]

for every \( i \sim j \). If we take the sum over all \( j \sim i \) in both sides of the inequality we will obtain

\[
\sum_{j \sim i} \nu \| \nabla j (E f) \| ^2 \leq (2 + 16kCJ^2) \sum_{j \sim i} \nu \| \nabla j f \| ^2 + (1 + 2C)^8 k^2 \nu (f - E f) \| ^2 +
\]

\[
32kCJ \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,i)=n} \nu \| \nabla r f \| ^2 + 32kCJ^2 \sum_{r \sim i} \nu \| \nabla r (E f) \| ^2
\]

If we choose \( J \) sufficiently small so that

\[
\frac{(1 + 4C)^8 kJ}{1 - 32kCJ^2} \leq (1 + 4C)^8 kJ \iff J \leq \frac{1}{32kC}
\]

we get

\[
\sum_{j \sim i} \nu \| \nabla j (E f) \| ^2 \leq \frac{(2 + 16kCJ^2) \nu \| \nabla j f \| ^2 + (1 + 4C)^8 kJ^2 \nu (f - E f) \| ^2 +}
\]

\[
(1 + 4C)^8 kJ \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,i)=n} \nu \| \nabla r f \| ^2
\]

Plugging the last one into (4.8) and choosing \( J \) small enough so that

\[
\frac{(2 + 16kCJ^2)C8kJ}{1 - 32kCJ^2} \leq 32kCJ \iff J \leq \frac{1}{72kC}
\]

we obtain

\[
\nu \| \nabla j (E f) \| ^2 \leq (2 + 16kCJ^2) \nu \| \nabla j f \| ^2 + (1 + 4C)^{12} k^2 \nu (f - E f) \| ^2 +
\]

\[
32CkJ^2 \nu \| \nabla j f \| ^2 + (1 + 4C)^{13} k^2 C_J \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,i)=n} \nu \| \nabla r f \| ^2
\]

which finishes the proof for appropriate chosen constant \( D_1 \).

Furthermore combining together (4.7) and Lemma 4.1, we obtain the following corollary.

**Corollary 4.2.** Assume that the measure \( \mu \) satisfies the log-Sobolev inequality and that the local specification has quadratic interactions \( V \) as in (2.1). Then, for \( J \) sufficiently small, for every \( j \sim i \) the following holds

\[
\nu((f - E f)^2d^2(x_j)) \leq D_2 \nu E_i (f - E f)^2 + D_2 \nu \| \nabla j f \| ^2 +
\]

\[
D_2 \sum_{n=0}^{\infty} J^n \sum_{\text{dist}(r,j)=n} \nu \| \nabla r f \| ^2
\]

for some constant \( D_2 > 0 \).
where in the above corollary we used again (4.9). The next lemma shows the Poincaré inequality for the one site measure \( E^i \) on the ball. The proof follows closely on the proof of a similar Poincaré inequality on the ball in [EKP] and the local Poincaré inequalities from [SC] and [V-SC-C].

**Lemma 4.3.** Define \( \eta(i, \omega) := d(x_i) + \sum_{j \neq i} d(\omega_j) \) and \( A^\omega(L) := \{ x_i \in M : \eta(i, \omega) \leq L \} \). For any \( L > 0 \) the following Poincaré type inequality on the ball holds

\[
E^i \omega |f - \frac{1}{|A^\omega(L)|} \int_{A^\omega(L)} f(z_i)dz_i|^2 \mathcal{I}_{\{\eta(i, \omega) \leq L\}} \leq D_L E^i \omega \|\nabla_i f\|^2
\]

for some positive constant \( D_L \), where \( |A^\omega(L)| := \int_{A^\omega(L)} dx_i \).

**Proof.** Denote

\[ V_L := E^i \omega |f - \frac{1}{|A^\omega(L)|} \int_{A^\omega(L)} f(z_i)dz_i|^2 \mathcal{I}_{\{\eta(i, \omega) \leq L\}} \]

where \( E^i \) has density \( \rho_i = \frac{e^{-H^i \omega}}{\int e^{-H^i \omega} dx_i} \). Since \( \phi(x_i) \geq 0 \) and \( J_{i,j} V(x_i, \omega_j) \geq 0 \) we can bound \( \rho_i \leq \frac{1}{Z^i \omega} \). This leads to

\[
(4.10) \quad V_L \leq \frac{1}{Z^i \omega} \int_{A^\omega(L)} |f(x_i) - \frac{1}{|A^\omega(L)|} \int_{A^\omega(L)} f(z_i)dz_i|^2 dx_i
\]

If we use the invariance of the \( dx_i \) measure we can write

\[
V_L \leq \frac{1}{Z^i \omega} \int_{A^\omega(L)} |f(x_i) - \frac{1}{|A^\omega(L)|} \int_{A^\omega(L)} f(x_i z_i) \mathcal{I}_{A^\omega(L)}(x_i z_i)dz_i|^2 dx_i
\]

\[
\leq \frac{1}{|A^\omega(L)|^2 Z^i \omega} \int_{A^\omega(L)} |f(x_i) - f(x_i z_i)\mathcal{I}_{A^\omega(L)}(x_i z_i)dz_i|^2 dx_i
\]

If we use Holder inequality and consider \( L \) sufficiently large so that \( |A^\omega(L)| > 1 \)

\[
(4.11) \quad V_L \leq \frac{1}{|A^\omega(L)| Z^i \omega} \int_{A^\omega(L)} \|f(x_i) - f(x_i z_i)\mathcal{I}_{A^\omega(L)}(x_i z_i)\|_{A^\omega(L)}(x_i)dz_i dx_i
\]

Consider \( \gamma : [0, t] \rightarrow M \) a geodesic from 0 to \( z_i \) such that \( |\dot{\gamma}(t)| \leq 1 \). Then for \( t = d(z_i) \) we can write

\[
|f(x_i) - f(x_i z_i)|^2 = \int_0^t \frac{d}{ds} f(x_i \gamma(s))ds |^2 = \int_0^t \nabla_i f(x_i \gamma(s)) \cdot \dot{\gamma}(s)ds |^2 \leq t \int_0^t \|\nabla_i f(x_i \gamma(s))\|^2 ds = d(z_i) \int_0^t \|\nabla_i f(x_i \gamma(s))\|^2 ds
\]

From the last inequality and (4.11) we get

\[
V_L \leq \frac{1}{|A^\omega(L)| Z^i \omega} \int_{A^\omega(L)} \int_0^t \|\nabla_i f(x_i \gamma(s))\|^2 ds \mathcal{I}_{A^\omega(L)}(x_i z_i)\mathcal{I}_{A^\omega(L)}(x_i)dz_i dx_i
\]

We observe that for \( x_i \in A^\omega(L) \) and \( x_i z_i \in A^\omega(L) \) we obtain

\[
d(z_i) = d(x_i^{-1} x_i z_i) \leq d(x_i^{-1}) + d(x_i z_i) \leq d(x_i) + d(x_i z_i) \leq 2L
\]
So
\[ V_L \leq \frac{2L}{|A^\omega(L)|Z^{|i,\omega|}} \int_0^t \int_0^t \| \nabla_i f(x_i(\gamma(s))) \|^2 I_{A^\omega(L)}(x_i) I_{A^\omega(L)}(z_i) dz_i dx_i \]

Similarly, for \( x_i \in A^\omega(L) \) and \( x_i z_i \in A^\omega(L) \) we calculate
\[ \eta(i, \omega)(z_i) = d(z_i) + \sum_{j \sim i} d(\omega_j) \leq d(x_i) + d(x_i z_i) + \sum_{j \sim i} d(\omega_j) \leq 2L \]
as well as
\[ \eta(i, \omega)(x_i \gamma(s)) = d(x_i \gamma(s)) + \sum_{j \sim i} d(\omega_j) \leq d(\gamma(s)) + d(x_i) + \sum_{j \sim i} d(\omega_j) \leq 3L \]

So, we can write
\[ V_L \leq \frac{2L}{|A^\omega(L)|Z^{|i,\omega|}} \int_0^t \int_0^t \| \nabla_i f(x_i(\gamma(s))) \|^2 I_{A^\omega(3L)}(x_i) I_{A^\omega(2L)}(z_i) ds dz_i dx_i \]

Using again the invariance of the \( dx_i \) measure
\[ V_L \leq \frac{2L}{|A^\omega(L)|Z^{|i,\omega|}} \int_0^t \int_0^t \| \nabla_i f(x_i) \|^2 I_{A^\omega(3L)}(x_i) I_{A^\omega(2L)}(z_i) ds dz_i dx_i \]
\[ = \frac{2L}{|A^\omega(L)|Z^{|i,\omega|}} \int_0^t \int_0^t d(z_i) \| \nabla_i f(x_i) \|^2 I_{A^\omega(3L)}(x_i) I_{A^\omega(2L)}(z_i) ds dz_i dx_i \]
\[ \leq \frac{4L^2}{|A^\omega(L)|Z^{|i,\omega|}} \int_0^t \int_0^t (\| \nabla_i f(x_i) \|^2 I_{A^\omega(3L)}(x_i)) dx_i I_{A^\omega(2L)}(z_i) dz_i \]
\[ \leq \frac{4L^2 |A^\omega(2L)|}{|A^\omega(L)|Z^{|i,\omega|}} \int_0^t \| \nabla_i f(x_i) \|^2 I_{A^\omega(3L)}(x_i) dx_i \]

For \( x_i \in A^\omega(3L) \), since \( d^2(x_i) \leq 9L^2 \) and \( d^2(\omega_j) \leq 9L^2 \) the Hamiltonian is bounded by
\[ H^{i,\omega} = \phi(x_i) + \sum_{j \sim i} J_{i,j} V(x_i, \omega_j) \leq \sup_{\{d(x) \leq 3L\}} \phi(x) + 4J + 4Jk d^2(x_i) + Jk \sum_{j \sim i} d^2(\omega_j) \]
\[ \leq \sup_{\{d(x) \leq 3L\}} \phi(x) + 72JkL^2 + 4J := F_L \]

So
\[ e^{-H^{i,\omega}} \geq e^{-F_L} \]
which gives the following bound
\[ V_L \leq \frac{4L^2}{e^{FL}} \frac{|A^\omega(2L)|}{|A^\omega(L)|Z^{|i,\omega|}} \int_0^t \| \nabla_i f(x_i) \|^2 e^{-H^{i,\omega}} dx_i \]
\[ = \frac{4L^2}{e^{FL}} \frac{|A^\omega(2L)|}{|A^\omega(L)|Z^{|i,\omega|}} \| \nabla_i f(x_i) \|^2 e^{-H^{i,\omega}} \]

If we take under account that
\[ \frac{|A^\omega(2L)|}{|A^\omega(L)|} \geq 1 \]
as well as
\[
\frac{|A^\omega(2L)|}{|A^\omega(L)|} \to 1 \quad \text{as} \quad \sum_{j \sim i} d(\omega_j) \to \infty
\]

we observe that \(\frac{|A^\omega(2L)|}{|A^\omega(L)|}\) is bounded from above uniformly on \(\omega\) from a constant. Thus, we finally obtain that
\[
V_L \leq D_L \mathbb{E}^i \|\nabla_i f(x_i)\|^2
\]
for some positive constant \(D_L\).

\[\square\]

The next lemma gives a bound for the variance of the one site measure \(\mathbb{E}^i\) outside \(A^\omega(L)\).

**Lemma 4.4.** Assume that the measure \(\mu\) satisfies the log-Sobolev inequality and that the local specification has quadratic interactions \(V\) as in (2.1). Then, for \(J\) sufficiently small the following bound holds
\[
\nu |f-m|^2 I_{\eta(i,\omega)>L} \leq D_3 \nu (\|\nabla_i f\|^2) + D_3 \sum_{n=1}^{\infty} J^{n-1} \sum_{r: \text{dist}(r,i)=n} \nu (\|\nabla_r f\|^2) +
\]
for any \(L > 5 + 2C\) and \(\forall m \in \mathbb{R}\).

**Proof.** We can write
\[
\mathbb{E}^i (|f-m|^2 I_{\eta(i,\omega)>L}) \leq \mathbb{E}^i \left( \frac{|f-m|^2 \eta(i,\omega)}{L} I_{\eta(i,\omega)>L} \right)
\]
\[
= \frac{1}{L} \mathbb{E}^i \left( |f-m|^2 \left( d(x_i) + \sum_{j \sim i} d(\omega_j) \right) I_{\eta(i,\omega)>L} \right)
\]
\[
\leq \frac{1}{L} \mathbb{E}^i \left( |f-m|^2 \left( d^2(x_i) + \sum_{j \sim i} d^2(\omega_j) + 5 \right) I_{\eta(i,\omega)>L} \right)
\]
since \(d(x) = d(x) I_{d(x) \leq 1} + d(x) I_{d(x) > 1} \leq 1 + d^2(x)\). If we take the expectation with respect to the Gibbs measure we get
\[
\nu (|f-m|^2 I_{\eta(i,\omega)>L}) \leq \frac{1}{L} \nu (|f-m|^2 d^2(x) I_{\eta(i,\omega)>L}) + 
\]
\[
\frac{1}{L} \sum_{j \sim i} \nu (|f-m|^2 d^2(\omega_j) I_{\eta(i,\omega)>L}) + \frac{5}{L} \nu (|f-m|^2 I_{\eta(i,\omega)>L})
\]
We can bound the first and second term on the right hand side from Proposition 2.4 to get

\[ \nu |f - m|^2 \mathcal{I}_{\{\eta(i,\omega) > L\}} \leq \frac{C}{L} \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,i) = n} \nu(\|\nabla_r f\|^2) + \frac{C}{L} \sum_{j \sim i} \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,j) = n} \nu(\|\nabla_r f\|^2) + \]

\[ \frac{5 + 5C}{L} \nu(|f - m|^2 \mathcal{I}_{\{\eta(i,\omega) > L\}}) \]

Which leads to

\[ \nu |f - m|^2 \mathcal{I}_{\{\eta(i,\omega) > L\}} \leq \frac{5C}{L} \nu(\|\nabla_i f\|^2) + \frac{5C}{L} \sum_{n=1}^{\infty} J^{n-1} \sum_{r: \text{dist}(r,i) = n} \nu(\|\nabla_r f\|^2) + \]

\[ \frac{5 + 5C}{L} \nu(|f - m|^2 \mathcal{I}_{\{\eta(i,\omega) > L\}}) \]

If we choose \( L \) sufficiently large so that \( \frac{5 + 5C}{L} < 1 \) we finally obtain

\[ \nu |f - m|^2 \mathcal{I}_{\{\eta(i,\omega) > L\}} \leq D_3 \nu(\|\nabla_i f\|^2) + D_3 \sum_{n=1}^{\infty} J^{n-1} \sum_{r: \text{dist}(r,i) = n} \nu(\|\nabla_r f\|^2) \]

for some constant \( D_3 > 0 \). \( \Box \)

We can now prove the Spectral Gap type inequality for the expectation with respect to the Gibbs measure of the one site variance \( \nu E |f - E^i f|^2 \)

Lemma 4.5. Assume that the measure \( \mu \) satisfies the log-Sobolev inequality and that the local specification has quadratic interactions \( V \) as in (2.1). Then, for \( J \) sufficiently small, the following spectral gap type inequality holds

\[ \nu E |f - E^i f|^2 \leq D_4 \nu(\|\nabla_i f\|^2) + D_4 \sum_{n=1}^{\infty} J^{n-1} \sum_{r: \text{dist}(r,i) = n} \nu(\|\nabla_r f\|^2) \]

for some constant \( D_4 \geq 1 \).

Proof. For any \( m \in \mathbb{R} \) we can bound the variance

\[ E^{i,\omega} |f - E^{i,\omega} f|^2 \leq 4 E^{i,\omega} |f - m|^2 \]

\[ = 4 E^{i,\omega} |f - m|^2 \mathcal{I}_{\{\eta(i,\omega) \leq L\}} + 4 E^{i,\omega} |f - m|^2 \mathcal{I}_{\{\eta(i,\omega) > L\}} \]

(4.12)

where we have again denoted

\[ \eta(i, \omega) = d(x_i) + \sum_{j \sim i} d(\omega_j) \]
Setting $m = \frac{1}{|A^\nu(L)|} \int_{A^\nu(L)} f(z)dz$ and taking the expectation with respect to the Gibbs measure in both sides of (4.12) gives

$$\nu |f - \mathbb{E}^{i_\omega} f|^2 \leq 4\nu |f - \frac{1}{|A^\nu(L)|} \int_{A^\nu(L)} f(z)dz|^2 I_{\eta(i,\omega) \leq L} + 4\nu |f - \frac{1}{|A^\nu(L)|} \int_{A^\nu(L)} f(z)dz|^2 I_{\eta(i,\omega) > L}$$

We can bound the first and the second term on the right hand side from Lemma 4.3 and Lemma 4.4 respectively. This leads to

$$\nu |f - \mathbb{E}^{i_\omega} f|^2 \leq 4(D_L + D_3)\nu \|\nabla_i f\|^2 + 4D_3 \sum_{n=1}^{\infty} J^{n-1} \sum_{r: \text{dist}(r,i) = n} \nu(\|\nabla_r f\|^2)$$

which proves the lemma for appropriate positive constant $D_4$. □

If we combine Lemma 4.5 and Corollary 4.2 we also have

**Corollary 4.6.** Assume that $\mu$ satisfies the log-Sobolev inequality and that the local specification has quadratic interactions $V$ as in (2.1). Then, for $J$ sufficiently small, the following holds

$$\nu((f - \mathbb{E}^{i_\omega} f)^2 d^2(x_j)) \leq D_5 \nu(\|\nabla_i f\|^2) + D_5 \sum_{n=1}^{\infty} J^{n-1} \sum_{r: \text{dist}(r,i) = n} \nu(\|\nabla_r f\|^2)$$

for some constant $D_5 \geq 1$.

The following lemma provides the sweeping out inequality for the one site measure

**Lemma 4.7.** Assume that the measure $\mu$ satisfies the log-Sobolev inequality and that the local specification has quadratic interactions $V$ as in (2.1). Then, for $J$ sufficiently small, for every $j \sim i$

$$\nu(\|\nabla_j(\mathbb{E}^{i_\omega} f)\|^2) \leq G_1 \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,j) = n} \nu(\|\nabla_r f\|^2)$$

for a constant $G_1 \in [1, \infty)$.

**Proof.** Combining Lemma 4.5 and Lemma 4.1 together, for $J$ sufficiently small, we obtain the following,

$$\nu(\|\nabla_j(\mathbb{E}^{i_\omega} f)\|^2) \leq J^2 D_1 D_4 \nu(\|\nabla_i f\|^2) + J^2 D_1 D_4 \sum_{n=1}^{\infty} J^{n-1} \sum_{r: \text{dist}(r,i) = n} \nu(\|\nabla_r f\|^2) + D_4 \nu(\|\nabla_j f\|^2) + J D_4 \sum_{n=1}^{\infty} J^n \sum_{r: \text{dist}(r,i) = n} \nu(\|\nabla_r f\|^2)$$

$$\leq D_1 \nu(\|\nabla_j f\|^2) + 2D_4 J \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,i) = n} \nu(\|\nabla_r f\|^2)$$
because $J < 1$ and $D_4 \geq 1$. Since $i \sim j$ that implies that every node $r$ which has distance $n$ from $i$, i.e. $r : \text{dist}(r, i) = n$, will have distance $n - 1$ or $n + 1$ from $j$. So the last inequality becomes:

$$
\nu \|\nabla_j (E^i f)\|^2 \leq D_1 \nu \|\nabla_j f\|^2 + 4D_4 D_1 J \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r, i) = n} \nu \|\nabla_r f\|^2
$$

and the lemma follows for $G_1 = D_1 + 4D_1 D_4$.

Define the following sets

$$
\Gamma_0 = (0, 0) \cup \{j \in \mathbb{Z}^2 : \text{dist}(j, (0, 0)) = 2m \text{ for some } m \in \mathbb{N}\}, \\
\Gamma_1 = \mathbb{Z}^2 \setminus \Gamma_0.
$$

where $\text{dist}(i, j)$ refers to the distance of the shortest path (number of vertices) between two nodes $i$ and $j$. Note that $\text{dist}(i, j) > 1$ for all $i, j \in \Gamma_k, k = 0, 1$ and $\Gamma_0 \cap \Gamma_1 = \emptyset$. Moreover $\mathbb{Z}^2 = \Gamma_0 \cup \Gamma_1$. In the next proposition we will prove a sweeping out inequality for the product measures $E_1^\Gamma$.

**Proposition 4.8.** Assume that the measure $\mu$ satisfies the log-Sobolev inequality and that the local specification has quadratic interactions $V$ as in (2.1). Then, for $J$ sufficiently small, the following sweeping out inequality is true

$$
\nu \|\nabla_{\Gamma_1} (E_{\Gamma_0} f)\|^2 \leq R_1 \nu \|\nabla_{\Gamma_1} f\|^2 + R_2 \nu \|\nabla_{\Gamma_0} f\|^2
$$

for constants $R_1 \in [1, \infty)$ and $0 < R_2 \leq \frac{JG_6}{1 - J} < 1$.

**Proof.** We can write

$$
(4.13) \quad \nu \|\nabla_{\Gamma_1} (E_{\Gamma_0} f)\|^2 = \sum_{i \in \Gamma_1} \nu \|\nabla_i (E_{\Gamma_0} f)\|^2 \leq \sum_{i \in \Gamma_1} \nu \|\nabla_i (E_{\sim i} f)\|^2
$$

If we denote $\{i_1, i_2, i_3, i_4\} := \{\sim i\}$ the neighbours of note $i$ as shown on Figure 1 and

\[\text{Figure 1. } \circ = \Gamma_0, \bullet = \Gamma_1\]
use Lemma 4.7 we get the following

\[ \nu \| \nabla_i (E^{(\sim i)} f) \|^2 = \nu \| \nabla_i (E^{i_1} E^{(i_2, i_3, i_4)} f) \|^2 \leq G_1 \nu \| \nabla_i (E^{(i_2, i_3, i_4)} f) \|^2 + G_1 \sum_{n=1}^{\infty} J^n \sum_{r: \text{dist}(r, i) = n} \nu (\| \nabla_r (E^{(i_2, i_3, i_4)} f) \|^2) \]

(4.14)

We will compute the second term in the right hand side of (4.14). For \( n = 1 \), we have

\[ \sum_{\text{dist}(r, i) = 1} \nu \| \nabla_r (E^{(i_2, i_3, i_4)} f) \|^2 = \nu \| \nabla_i (E^{(i_2, i_3, i_4)} f) \|^2 + \sum_{r = i_2, i_3, i_4} \nu \| \nabla_r (E^{(i_2, i_3, i_4)} f) \|^2 \]

(4.15)

\[ \leq \nu \| \nabla_i f \|^2 \]

For \( n = 2 \), we distinguish between the nodes \( r \) in \( \{ \text{dist}(r, i) = 2 \} \) which neighbour only one of the neighbours \( \{ i_2, i_3, i_4 \} \) of \( i \), which are the \( i_2', i_3', i_4', i_{12}, i_{14} \), and those which neighbour two of the node in \( \{ i_2, i_3, i_4 \} \), which are the \( i_{23} \) and \( i_{34} \) neighbouring \( i_2, i_3 \) and \( i_3, i_4 \) respectively, as shown in Figure 1. We can then write

\[ \sum_{\text{dist}(r, i) = 2} \nu \| \nabla_r (E^{(i_2, i_3, i_4)} f) \|^2 = \sum_{r = i_{23}, i_{34}} \nu \| \nabla_r (E^{(i_2, i_3, i_4)} f) \|^2 + \sum_{r = i_2', i_3', i_4', i_{12}, i_{14}} \nu \| \nabla_r (E^{(i_2, i_3, i_4)} f) \|^2 \]

(4.16)

To bound the second term on the right hand side of (4.16), for any \( r \in \{ i_2', i_3', i_4', i_{12}, i_{14} \} \) neighbouring the node \( t \in \{ i_2, i_3, i_4 \} \) we use Lemma 4.7

\[ \nu \| \nabla_r (E^{(i_2, i_3, i_4)} f) \|^2 = \nu \| \nabla_r (E^{(t)} (E^{(i_2, i_3, i_4)} \sim (t)) f) \|^2 \leq \nu \| \nabla_r (E^t f) \|^2 \leq G_1 \sum_{n=0}^{\infty} J^n \sum_{s: \text{dist}(s, r) = n} \nu (\| \nabla s f \|^2) \]

which leads to

\[ \sum_{r = i_2', i_3', i_4', i_{12}, i_{14}} \nu \| \nabla_r (E^{(i_2, i_3, i_4)} f) \|^2 \leq G_1 \sum_{\text{dist}(r, i) = 2} \sum_{n=0}^{\infty} J^n \sum_{s: \text{dist}(s, r) = n} \nu (\| \nabla s f \|^2) \]

Since for nodes \( r : \text{dist}(r, i) = 2 \), the nodes \( s \) such that \( \text{dist}(s, r) = n \) have distance from \( i \) equal to \(|n - 2|\), \( n \) or \( n + 2 \) we get

\[ \sum_{r = i_2', i_3', i_4', i_{12}, i_{14}} \nu \| \nabla_r (E^{(i_2, i_3, i_4)} f) \|^2 \leq 8G_1 J \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r, i) = n} \nu \| \nabla s f \|^2 +
\]

(4.17)

\[ 8G_1 J \sum_{n=2}^{\infty} J^{n-2} \sum_{r: \text{dist}(r, i) = n} \nu \| \nabla f \|^2 \]
To bound the first term on the right hand side of (4.16), for example for \( r = i_{23} \) neighbouring the nodes \( i_2 \) and \( i_3 \) we use again Lemma 4.7.

\[
\nu \| \nabla_{i_{23}} \left( \mathbb{E}^{i_{2},i_{3},i_{4}} f \right) \|^2 \leq \nu \| \nabla_{i_{23}} \left( \mathbb{E}^{i_{2},i_{3}} f \right) \|^2 \leq G_1 \sum_{n=0}^{\infty} J^n \sum_{s: \text{dist}(s,i_{23})=n} \nu \| \nabla_s (\mathbb{E}^{i_3} f) \|^2
\]

The first term for \( n = 0 \) on the sum of (4.18) by Lemma 4.7 is bounded by

\[
\nu \| \nabla_{i_{23}} \left( \mathbb{E}^{i_3} f \right) \|^2 \leq G_1 J \sum_{n=0}^{\infty} \sum_{r: \text{dist}(s,i_{23})=n} \nu \| \nabla_s f \|^2 \leq G_1 J \sum_{n=0}^{1} \sum_{r: \text{dist}(s,i_{23})=n} \nu \| \nabla_s f \|^2 + G_1 \sum_{n=2}^{\infty} J^{n-2} \sum_{r: \text{dist}(r,i_{23})=n} \nu \| \nabla_r f \|^2
\]

The terms for \( n = 1 \) on the sum of (4.18) become

\[
G_1 J \sum_{s: \text{dist}(s,i_{23})=1} \nu \| \nabla_s (\mathbb{E}^{i_3} f) \|^2 \leq G_1 J \sum_{s: \text{dist}(s,i_{1,3})=1, 3} \nu \| \nabla_s f \|^2
\]

The terms for \( n = 2 \) on the sum of (4.18) can be divided on those that neighbour \( i_3 \) and those that not

\[
\sum_{s: \text{dist}(s,i_{23})=2} \nu \| \nabla_s (\mathbb{E}^{i_3} f) \|^2 = \sum_{s: \text{dist}(s,i_{23})=2, s \sim i_3} \nu \| \nabla_s (\mathbb{E}^{i_3} f) \|^2 + \sum_{s: \text{dist}(s,i_{23})=2, s \not\sim i_3} \nu \| \nabla_s (\mathbb{E}^{i_3} f) \|^2
\]

For the second term on the right hand side of (4.21)

\[
\sum_{s: \text{dist}(s,i_{23})=2, s \sim i_3} \nu \| \nabla_s (\mathbb{E}^{i_3} f) \|^2 \leq \sum_{s: \text{dist}(s,i_{23})=2, s \sim i_3} \nu \| \nabla_s f \|^2
\]

While for the first term on the right hand side of (4.21) we can use Lemma 4.7

\[
\sum_{s: \text{dist}(s,i_{23})=2, s \sim i_3} \nu \| \nabla_s (\mathbb{E}^{i_3} f) \|^2 \leq G_1 \sum_{s: \text{dist}(s,i_{23})=2, s \sim i_3} \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r,s)=n} \nu \| \nabla_r f \|^2 \leq 4G_1 \sum_{n=0}^{1} J^n \sum_{r: \text{dist}(r,i)=n} \nu \| \nabla_s f \|^2 + 4G_1 \sum_{n=2}^{\infty} J^{n-2} \sum_{r: \text{dist}(r,i)=n} \nu \| \nabla_r f \|^2
\]
From (4.21)-(4.23) we get the following bound for the terms for \( n = 2 \) on the sum of (4.18)

\[
G_1 J_2^2 \sum_{s: \text{dist}(s, i_{23})=2} \nu \| \nabla_s (E^{i_2,i_3} f) \|^2 \leq G_1 J_2^2 \sum_{s: \text{dist}(s, i)=2,4} \nu \| \nabla_s f \|^2 +
\]

(4.24)

\[
4G_1^2 \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r, i)=n} \nu \| \nabla_r f \|^2
\]

Finally, for the terms for \( n > 2 \) on the sum on the right hand side of (4.18), we get

\[
G_1 \sum_{n=3}^{\infty} J^n \sum_{r: \text{dist}(s, i_{23})=n} \nu \| \nabla_s (E^{i_2,i_3,i_4} f) \|^2 \leq G_1 \sum_{n=3}^{\infty} J^{n-2} \sum_{r: \text{dist}(s, i)=n} \nu \| \nabla_s f \|^2
\]

(4.25)

If we put (4.19), (4.20), (4.24) and (4.25) in (4.18) we get

\[
\nu \| \nabla_{i_{23}} (E^{i_2,i_3,i_4} f) \|^2 \leq G_2 \sum_{n=0}^{1} J^n \sum_{r: \text{dist}(s, i)=n} \nu \| \nabla_s f \|^2 +
\]

(4.26)

\[
G_2 \sum_{n=2}^{\infty} J^{n-2} \sum_{r: \text{dist}(s, i)=n} \nu \| \nabla_s f \|^2
\]

for \( G_2 = 4G_1^2 + 3G_1 \). Exactly the same bound can be obtain for the other term, \( \nu \| \nabla_{i_{34}} (E^{i_2,i_3,i_4} f) \|^2 \), on the first sum of the right hand side of (4.18). Gathering together, (4.16), (4.17) and (4.26)

\[
\sum_{\text{dist}(r, i)=2} \nu \| \nabla_r (E^{i_2,i_3,i_4} f) \|^2 = G_3 \sum_{n=0}^{1} J^n \sum_{r: \text{dist}(s, i)=n} \nu \| \nabla_s f \|^2 +
\]

(4.27)

\[
G_3 \sum_{n=2}^{\infty} J^{n-2} \sum_{r: \text{dist}(s, i)=n} \nu \| \nabla_s f \|^2
\]

for \( G_3 = 8G_1 + 2G_2 \).

Furthermore, for every \( r: \text{dist}(r, i) \geq 3 \),

\[
\nu \| \nabla_r (E^{i_2,i_3,i_4} f) \|^2 \leq \nu \| \nabla_r f \|^2
\]

(4.28)

Finally, if we put (4.15) and (4.27) and (4.28) in (4.14) we obtain

\[
\nu \| \nabla_i (E^{i_{-1}} f) \|^2 = \nu \| \nabla_i (E^{i_1,i_2,i_3,i_4} f) \|^2 \leq G_4 \nu \| \nabla_i (E^{i_2,i_3,i_4} f) \|^2 +
\]

(4.29)

\[
G_4 \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r, i)=n} \nu \| \nabla_r f \|^2
\]

for constant \( G_4 = G_1 G_3 + G_1 \).

If we repeat the same calculation recursively for the first term on the right hand side of (4.29), then for \( \nu \| \nabla_i (E^{i_2,i_4} f) \|^2 \) and \( \nu \| \nabla_i (E^{i_4} f) \|^2 \) we will finally obtain

\[
\nu \| \nabla_i (E^{i_{-1}} f) \|^2 \leq G_5 \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(s, i)=n} \nu \| \nabla_s f \|^2
\]
for a constant $G_5 > 1$. From the last inequality and \([4.13]\) we get
\[
\nu \|\nabla_{\Gamma_1}(E^{\Gamma_0} f)\|^2 \leq R_1 \nu \|\nabla_{\Gamma_1} f\|^2 + R_2 \nu \|\nabla_{\Gamma_0} f\|^2
\]
for a constant $R_2 \leq G_5 J(\sum_{k=0}^{\infty}(4J)^k) \leq \frac{JG_5}{1-4} < 1$ for $J$ sufficiently small such that $J < \min\{\frac{1}{4}, \frac{1}{C_5+4}\}$.

5. Second Sweeping out relations.

In this section we prove the second sweeping out relation. We start by first proving in the next lemma the second sweeping out relation between two neighbouring nodes.

**Lemma 5.1.** Assume that the measure $\mu$ satisfies the log-Sobolev inequality and that the local specification has quadratic interactions $V$ as in \([2.1]\). Then, for $J$ sufficiently small, for every $i \sim j$ the following sweeping out inequality holds
\[
\nu \|\nabla_i(E^j |f|^2)^{\frac{1}{2}}\|^2 \leq R_3 \sum_{n=0}^{\infty} J^n \sum_{\text{dist}(r,i)=n} \nu \|\nabla_rf\|^2
\]
for $R_3 \geq 1$.

**Proof.** Consider the (sub)gradient $\nabla_i = (X^1_i, X^2_i, ..., X^N_i)$. We can then write
\[
(5.1) \quad \|\nabla_i(E^j |f|^2)^{\frac{1}{2}}\|^2 = \sum_{k=1}^{N} (X^j_k(E^j |f|^2)^{\frac{1}{2}})^2
\]
Then for every $k \in \{1, ..., N\}$ we can compute
\[
(5.2) \quad |X^j_k(E^j |f|^2)^{\frac{1}{2}}|^2 = \frac{1}{2}(E^j |f|^2)^{\frac{1}{2}-1}X^j_k(E^j |f|^2) = \frac{1}{4}(E^j |f|^2)^{-1}|X^j_k(E^j |f|^2)|^2
\]
But from relationship \([4.2]\) of Lemma 4.1 if we put $f^2$ in $f$, we have
\[
(5.3) \quad |X^j_k(E^j |f|^2)|^2 \leq 2 \int X^j_k(f^2)\rho_j dx_j |^2 + 2 |\int f^2(X^j_k\rho_j)dx_j|^2
\]
where again $\rho_j$ denotes the density of $E^j$. For the second term in \([5.3]\) we have
\[
(5.4) \quad |\int f^2(X^j_k\rho_j)dx_j|^2 \leq J^2 |E^j(f^2; X^j_k V(x_j, x_i))|^2
\]
While for the first term of \([5.3]\) the following bound holds
\[
(5.5) \quad |\int X^j_k(f^2)\rho_j dx_j|^2 \leq 2 |E^j(f(X^j_k f))|^2 \leq 2 (E^j f^2) \left(\frac{E^j |X^j_k f|^2}{2}\right)
\]
where above we used the Cauchy-Swartz inequality. If we plug \([5.4]\) and \([5.5]\) in \([5.3]\) we get
\[
(5.6) \quad |X^j_k(E^j |f|^2)|^2 \leq 4 (E^j f^2) \left(\frac{E^j |X^j_k f|^2}{2}\right) + 2J^2 |E^j(f^2; X^j_k V(x_j, x_i))|^2
\]
Combining together \([5.2]\) and \([5.6]\) we obtain
\[
(5.7) \quad |X^j_k(E^j |f|^2)^{\frac{1}{2}}|^2 \leq E^j |X^j_k f|^2 + J^2(E^j f^2)^{-1}|E^j(f^2; X^j_k V(x_j, x_i))|^2
\]
In order to calculate the second term on the right hand side of \([5.7]\) we will use the following lemma.
Lemma 5.2. For any probability measure \( \mu \) the following inequality holds

\[
\mu(|f|^2; g) \leq \hat{c} \left( \mu(|f|^2)^{\frac{1}{2}} \left( \mu(|f - \mu f|^2 + \mu|g|^2) \right)^{\frac{1}{2}} \right)
\]

for some constant \( \hat{c} \) uniformly on the boundary conditions.

Without loose of generality we can assume \( \hat{c} \geq 1 \). The proof of Lemma 5.2 can be found in [Pa1]. Applying this bound to the second term in (5.7) leads to

\[
(\mathbb{E} f)^{-1} |\mathbb{E} f(x, x)|^2 \leq \hat{c}^2 \mathbb{E} f \left[ |f - \mathbb{E} f|^2 \left( (X_n^k V(x, x_n))^2 + \mathbb{E} f(x, x_n)^2 \right) \right]
\]

From the last inequality and (5.7) we have

\[
|X_n^k(\mathbb{E} f)^{\frac{1}{2}}|^2 \leq \mathbb{E} \|\nabla_2 \mathbb{E} f\|^2 + J^2 \hat{c}^2 \mathbb{E} f \left[ |f - \mathbb{E} f|^2 \|\nabla_2 \mathbb{E} f(x, x_n)\|^2 \right] + J^2 \hat{c}^2 \mathbb{E} f \left[ |f - \mathbb{E} f|^2 \|\nabla_2 \mathbb{E} f(x, x_n)\|^2 \right]
\]

Putting this in (5.1) leads to

\[
\|\nabla_2 \mathbb{E} f \|^2 = \mathbb{E} \|\nabla_2 \mathbb{E} f\|^2 + J^2 \hat{c}^2 \mathbb{E} f \left[ |f - \mathbb{E} f|^2 \|\nabla_2 \mathbb{E} f(x, x_n)\|^2 \right] + J^2 \hat{c}^2 \mathbb{E} f \left[ |f - \mathbb{E} f|^2 \|\nabla_2 \mathbb{E} f(x, x_n)\|^2 \right]
\]

If we take the expectation with respect to the Gibbs measure and bound \( \|\nabla_2 \mathbb{E} f(x, x_n)\|^2 \) by (2.1) we get

\[
\nu \|\nabla_2 (\mathbb{E} f)^{\frac{1}{2}}\|^2 \leq \nu \|\nabla_2 \mathbb{E} f\|^2 + 2k J^2 \hat{c}^2 \nu \left[ |f - \mathbb{E} f|^2 d^2(x_j) \right] + k J^2 \hat{c}^2 \nu \left[ |f - \mathbb{E} f|^2 \mathbb{E} f^2(x_j) \right] + k J^2 \hat{c}^2 \nu \left[ |f - \mathbb{E} f|^2 \mathbb{E} f^2(x_j) \right]
\]

If we bound the second and third term on the right hand side by Corollary 4.6 we get

\[
\nu \|\nabla_2 (\mathbb{E} f)^{\frac{1}{2}}\|^2 \leq \nu \|\nabla_2 \mathbb{E} f\|^2 + 3k J^2 \hat{c}^2 \nu \left( \|\nabla f\|^2 \right) + 3k J^2 \hat{c}^2 \nu \sum_{n=1}^{\infty} J^n \sum_{r: \text{dist}(r,j)=n} \nu \left( \|\nabla f\|^2 \right) + k J^2 \hat{c}^2 \nu \left[ |f - \mathbb{E} f|^2 \mathbb{E} f^2(x_j) \right]
\]

For the last term on the right hand side of (5.8) we can write

\[
\nu \left[ |f - \mathbb{E} f|^2 \mathbb{E} f^2(x_j) \right] = \nu \left[ |\mathbb{E} f|^2 \mathbb{E} f^2(x_j) \right]
\]

and now apply the U-bound inequality (2.5) of Proposition 2.3

\[
\nu \left[ |f - \mathbb{E} f|^2 \mathbb{E} f^2(x_j) \right] \leq C \nu \left( |f - \mathbb{E} f|^2 \right) + C \sum_{n=1}^{\infty} J^n \sum_{r: \text{dist}(r,j)=n} \nu \left( \|\nabla f\|^2 \right)
\]
In order to bound the variance on the first term on the right hand side we can use the spectral gap type inequality of Lemma 4.5

\[ \nu \left[ |f - E_j f|^2 d^2(x_j) \right] \leq CD_4 \nu \| \nabla_j f \|^2 + CD_4 \sum_{n=1}^{\infty} J^{n-1} \sum_{r: \text{dist}(r, j) = n} \nu \| \nabla_r f \|^2 + \]

(5.9)

\[ C \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r, j) = n} \nu \| \nabla_r (E_j | f - E_j f |^2)^{\frac{1}{2}} \|^2 \]

For \( n = 0 \) the term of the second sum is zero, while for \( n > 1 \) the nodes do not neighbour with \( j \), so we have

\[ \| \nabla_r (E_j | f - E_j f |^2)^{\frac{1}{2}} \|^2 = \sum_{k=1}^{N} |X_k^r (E_j | f - E_j f |^2)^{\frac{1}{2}} |^2 = \]

\[ \frac{1}{4} \sum_{k=1}^{N} (E_j | f - E_j f |^2)^{-\frac{1}{2}} X_k^r (E_j | f - E_j f |^2)^{\frac{1}{2}} \leq \]

\[ \sum_{k=1}^{N} (E_j | f - E_j f |^2)^{-\frac{1}{2}} E_j \left[ (f - E_j f) \left( |X_k^r f| + E_j |X_k^r f| \right) \right] \]

From Cauchy-Swartz inequality the last becomes

(5.10) \[ \| \nabla_r (E_j | f - E_j f |^2)^{\frac{1}{2}} \|^2 \leq 2 \sum_{k=1}^{N} E_j |X_k^r f|^2 = 2E_j \| \nabla_r f \|^2 \]

Putting together (5.9) and (5.10)

\[ \nu \left[ |f - E_j f|^2 d^2(x_j) \right] \leq CJ \sum_{r \sim j} \nu \| \nabla_r (E_j | f - E_j f |^2)^{\frac{1}{2}} \|^2 + CD_4 \nu \| \nabla_j f \|^2 + \]

(5.11)

\[ (CD_4 + 2C) \sum_{n=1}^{\infty} J^{n-1} \sum_{dist(r, j) = n} \nu \| \nabla_r f \|^2 \]

From (5.8) and (5.11) we get

\[ \nu \| \nabla_i (E_j f^2)^{\frac{1}{2}} \|^2 \leq D_6 \nu \| \nabla_i f \|^2 + D_6 J^3 + D_6 J \sum_{n=0}^{\infty} J^n \sum_{dist(r, j) = n} \nu \| \nabla_r f \|^2 + \]

(5.12)

\[ \sum_{r \sim j} \nu \| \nabla_r (E_j | f - E_j f |^2)^{\frac{1}{2}} \|^2 \]
for a constant $D_6 = 1 + k^2 (3D_6 + CD_4 + 2C)$. If we replace $f$ by $f - \mathbb{E}^j f$ in (5.12) we get

\[ \nu \| \nabla_i (\mathbb{E}^j (f - \mathbb{E}^j f)^2) \| ^2 \leq D_6 \nu \| \nabla_i (f - \mathbb{E}^j f) \| ^2 + D_6 J^3 \sum_{r \sim i} \nu \| \nabla_r (\mathbb{E}^j |f - \mathbb{E}^j f|^2) \| ^2 + \]

\[ D_6 J \sum_{n=0}^{\infty} J^n \sum_{\text{dist}(r,j)=n} \nu \| \nabla_r (f - \mathbb{E}^j f) \| ^2 \leq \]

\[ 2D_6 \nu \| \nabla_i f \| ^2 + 2D_6 \nu \| \nabla_i (\mathbb{E}^j f) \| ^2 + D_6 J^3 \sum_{r \sim j} \nu \| \nabla_r (\mathbb{E}^j |f - \mathbb{E}^j f|^2) \| ^2 + \]

\[ 2D_6 J^2 \sum_{\text{dist}(r,j)=1} \nu \| \nabla_r (\mathbb{E}^j f) \| ^2 + 2D_6 J \sum_{n=0}^{\infty} J^n \sum_{\text{dist}(r,j)=n} \nu \| \nabla_r f \| ^2 \]

If we use Lemma 4.7 to bound the second and fourth term in the right hand side of the last inequality we obtain

\[ \nu \| \nabla_i (\mathbb{E}^j (f - \mathbb{E}^j f)^2) \| ^2 \leq 2D_6 (G_1 + 1) \sum_{n=0}^{\infty} J^n \sum_{\text{dist}(r,i)=n} \nu \| \nabla_r f \| ^2 + \]

\[ D_6 J^3 \sum_{r \sim j} \nu \| \nabla_r (\mathbb{E}^j |f - \mathbb{E}^j f|^2) \| ^2 + \]

\[ 2G_1 D_6 J^2 \sum_{\text{dist}(r,j)=1} \nu \| \nabla_r (\mathbb{E}^j f) \| ^2 + \]

\[ 2D_6 J \sum_{n=0}^{\infty} J^n \sum_{\text{dist}(r,j)=n} \nu \| \nabla_r f \| ^2 \]

Since $i$ and $j$ are neighbours and the $r$’s in the sum of the third term have distance less or equal to two from $i$, we can write

\[ \nu \| \nabla_i (\mathbb{E}^j (f - \mathbb{E}^j f)^2) \| ^2 \leq D_7 \sum_{n=0}^{\infty} J^n \sum_{\text{dist}(r,i)=n} \nu \| \nabla_r f \| ^2 + \]

\[ D_7 J^3 \sum_{r \sim j} \nu \| \nabla_r (\mathbb{E}^j |f - \mathbb{E}^j f|^2) \| ^2 \]

for a constant $D_7 = 24D_6 G_1 + 2D_6$. If we take the sum over all $i$ such that $i \sim j$ we get

\[ \sum_{r \sim j} \nu \| \nabla_r (\mathbb{E}^j |f - \mathbb{E}^j f|^2) \| ^2 \leq 4D_7 \sum_{n=1}^{\infty} J^{n-1} \sum_{\text{dist}(r,j)=n} \nu \| \nabla_r f \| ^2 + \]

\[ 4D_7 J \nu \| \nabla_r f \| ^2 + \]

\[ 4D_7 J^3 \sum_{r \sim j} \nu \| \nabla_r (\mathbb{E}^j |f - \mathbb{E}^j f|^2) \| ^2 \]
For $J$ sufficiently small so that $\frac{1}{1 - 4D_6J^3} < 2$ we obtain

$$\sum_{r \sim j} \nu \|\nabla_i (\mathbb{E}^j f - \mathbb{E}^j f^2) \|_2^2 \leq 8D_7 \sum_{n=1}^{\infty} J^{n-1} \sum_{r : \text{dist}(s, j) = n} \nu \|\nabla_s f\|_2^2 + 8D_7J \nu \|\nabla_j f\|_2^2$$

If we use the last inequality to bound the last term on the right hand side of (5.12) we obtain

$$\nu \|\nabla_i (\mathbb{E}^j f) \|_2^2 \leq D_6 \nu \|\nabla_i f\|_2^2 + 8D_7D_6J^3 \sum_{n=1}^{\infty} J^{n-1} \sum_{r : \text{dist}(s, i) = n} \nu \|\nabla_s f\|_2^2 + 8D_7J^2 \nu \|\nabla_j f\|_2^2$$

$$\leq 2D_6 \nu \|\nabla_i f\|_2^2 + (16D_7D_6J^2 + D_6) \sum_{n=1}^{\infty} J^n \sum_{r : \text{dist}(s, i) = n} \nu \|\nabla_s f\|_2^2$$

where above we used (4.9). This finishes the proof for an appropriate constant $R_3$. \(\Box\)

In the next proposition we will extend the sweeping out relations of the last lemma to the two neighboring nodes to the two infinite dimensional disjoint sets $\Gamma_0$ and $\Gamma_1$.

**Proposition 5.3.** Assume that the measure $\mu$ satisfies the log-Sobolev inequality and that the local specification has quadratic interactions $V$ as in (2.1). Then, for $J$ sufficiently small, the following sweeping out inequality holds

$$\nu \|\nabla_{\Gamma_i} (\mathbb{E}_{\Gamma_j} f^2) \|_2^2 \leq C_1 \nu \|\nabla_{\Gamma_i} f\|_2^2 + C_2 \nu \|\nabla_{\Gamma_j} f\|_2^2$$

for $\{i, j\} = \{0, 1\}$ and constants $C_1 \in [1, \infty)$ and $0 < C_2 < 1$.

**Proof.** The proof will follow the same lines of the proof of Proposition 4.8. If we denote $\sim i = \{i_1, i_2, i_3, i_4\}$ the neighbours of note $i$, then we can write

$$\nu \|\nabla_{\Gamma_i} (\mathbb{E}_{\Gamma_0} f^2) \|_2^2 = \sum_{i \in \Gamma_1} \nu \|\nabla_i (\mathbb{E}_{\Gamma_0} f^2) \|_2^2 \leq \sum_{i \in \Gamma_1} \nu \|\nabla_i (\mathbb{E}^{\sim i} f^2) \|_2^2$$

We can use Lemma 5.1 to bound the last one

$$\nu \|\nabla_i (\mathbb{E}^{\sim i} f^2) \|_2^2 = \nu \|\nabla_i (\mathbb{E}^{i_1} \mathbb{E}^{i_2, i_3, i_4} f^2) \|_2^2 \leq R_3 \nu \|\nabla_i (\mathbb{E}^{i_2, i_3, i_4} f^2) \|_2^2$$

(5.15)

$$R_3 \sum_{i=1}^{\infty} J^n \sum_{\text{dist}(r, i) = n} \nu \|\nabla_r (\mathbb{E}^{i_2, i_3, i_4} f^2) \|_2^2$$

We will compute the second term in the right hand side of (5.15). For $n = 1$, we have

$$\sum_{\text{dist}(r, i) = 1} \nu \|\nabla_r (\mathbb{E}^{i_2, i_3, i_4} f^2) \|_2^2 \leq \nu \|\nabla_{i_1} (\mathbb{E}^{i_2, i_3, i_4} f^2) \|_2^2 + \sum_{r = i_2, i_3, i_4} \nu \|\nabla_r (\mathbb{E}^{i_2, i_3, i_4} f^2) \|_2^2$$

(5.16)

$$\leq \nu \|\nabla_{i_1} f\|_2^2$$

For $n = 2$, we distinguish between the nodes $r$ in $\{\text{dist}(r, i) = 2\}$ which neighbour only one of the neighbours $\{i_2, i_3, i_4\}$ of $i$, which are the $i'_2, i'_3, i'_4, i_{12}, i_{14}$, and these which
neighbour two of the node in \{i_2, i_3, i_4\}, which are the \(i_{23k}\) and \(i_{34}\) neighbouring \(i_2, i_3\) and \(i_3, i_4\) respectively, as shown in Figure 1. We can then write

\[
\sum_{\text{dist}(r,i)=2} \nu \|\nabla_r (\mathbb{E}^{(i_2,i_3,i_4)} f^2)^{1/2} \|^2 = \sum_{r=i_{23},i_{34}} \sum_{\text{neighbour two of the node in } \{i_2, i_3, i_4\}} \nu \|\nabla_i (\mathbb{E}^{(i_2,i_3,i_4)} f^2)^{1/2} \|^2 + \\
(5.17) \sum_{r=i_{234},i_{12},i_{14}} \nu \|\nabla_r (\mathbb{E}^{(i_2,i_3,i_4)} f^2)^{1/2} \|^2
\]

To bound the second term on the right hand side of (5.17), for any \(r \in \{i_2, i_3, i_4\}\) we use Lemma 5.1

\[
\nu \|\nabla_r (\mathbb{E}^{(i_2,i_3,i_4)} f^2)^{1/2} \|^2 \leq \nu \|\nabla_r (\mathbb{E}^{(i_2,i_3,i_4)} f^2)^{1/2} \|^2 \leq R_3 \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(s,r)=n} \nu \|\nabla_s f\|^2
\]

which leads to

\[
\sum_{r=i_{234},i_{12},i_{14}} \nu \|\nabla_r (\mathbb{E}^{(i_2,i_3,i_4)} f^2)^{1/2} \|^2 \leq R_3 \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(s,r)=n} \nu \|\nabla_s f\|^2
\]

Since for nodes \(r : \text{dist}(r, i) = 2\), the nodes \(s\) such that \(\text{dist}(s, r) = n\) have distance from \(i\) equal to \(n - 2, n\) or \(n + 2\) we get

\[
\sum_{r=i_{234},i_{12},i_{14}} \nu \|\nabla_r (\mathbb{E}^{(i_2,i_3,i_4)} f^2)^{1/2} \|^2 \leq 8R_3J^2\nu \|\nabla_i f\|^2 + 8R_3J \sum_{r: \text{dist}(s,r)=1} \nu \|\nabla_s f\|^2 + \\
(5.18) 8R_3 \sum_{n=2}^{\infty} J^{n-2} \sum_{r: \text{dist}(s,r)=n} \nu \|\nabla_s f\|^2
\]

To bound the first term on the right hand side of (5.17), for example for \(r = i_{23}\) neighbouring the nodes \(i_2\) and \(i_3\) we use again Lemma 5.1

\[
\nu \|\nabla_{i_{23}} (\mathbb{E}^{(i_2,i_3,i_4)} f^2)^{1/2} \|^2 \leq \nu \|\nabla_{i_{23}} (\mathbb{E}^{(i_2,i_3)} f^2)^{1/2} \|^2 \leq \\
(5.19) R_3 \nu \|\nabla_{i_{23}} (\mathbb{E}^{(i_2,i_3)} f^2)^{1/2} \|^2 + R_3 \sum_{n=1}^{\infty} J^n \sum_{r: \text{dist}(s,r)=n} \nu \|\nabla_s (\mathbb{E}^{(i_2,i_3)} f^2)^{1/2} \|^2
\]

The first term on the right hand side of (5.19) by Lemma 5.1 is bounded by

\[
\nu \|\nabla_{i_{23}} (\mathbb{E}^{(i_2,i_3)} f^2)^{1/2} \|^2 \leq R_3 \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(s,i_{23})=n} \nu \|\nabla_s f\|^2 \leq \\
\leq R_3J^2\nu \|\nabla_i f\|^2 + R_3J \sum_{r: \text{dist}(s,i)=1} \nu \|\nabla_s f\|^2 + \\
(5.20) R_3 \sum_{n=2}^{\infty} J^{n-2} \sum_{r: \text{dist}(s,i)=n} \nu \|\nabla_s f\|^2
\]
The term for $n = 1$ in the sum in the second term on the right hand side of (5.19) becomes
\[
R_3 J \sum_{r: \text{dist}(s, i_{23}) = 1} \nu \| \nabla_s (E_i f^2)^{\frac{1}{2}} \|^2 \leq R_3 J \sum_{r: \text{dist}(s, i_{23}) = 1} \nu \| \nabla_s f \|^2 \leq R_3 J \sum_{r: \text{dist}(s, i) = 3} \nu \| \nabla_s f \|^2
\]
(5.21)

The terms for $n = 2$ on the sum of (5.19) can be divided on those that neighbour $i_{23}$ and those that not
\[
\sum_{s: \text{dist}(s, i_{23}) = 2} \nu \| \nabla_s (E_i f^2)^{\frac{1}{2}} \|^2 = \sum_{s: \text{dist}(s, i_{23}) = 2, s \sim i_3} \nu \| \nabla_s (E_i f^2)^{\frac{1}{2}} \|^2 + \sum_{s: \text{dist}(s, i_{23}) = 2, s \not\sim i_3} \nu \| \nabla_s f \|^2
\]
(5.22)

For the second term on the right hand side of (5.22)
\[
\sum_{s: \text{dist}(s, i_{23}) = 2, s \not\sim i_3} \nu \| \nabla_s (E_i f^2)^{\frac{1}{2}} \|^2 \leq \sum_{s: \text{dist}(s, i_{23}) = 2, s \not\sim i_3} \nu \| \nabla_s f \|^2
\]
(5.23)
while for the first term on the right hand side of (5.22) we can use Lemma 5.1
\[
\sum_{s: \text{dist}(s, i_{23}) = 2, s \sim i_3} \nu \| \nabla_s (E_i f^2)^{\frac{1}{2}} \|^2 \leq R_3 \sum_{s: \text{dist}(s, i_{23}) = 2, s \sim i_3} \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r, s) = n} \nu \| \nabla_r f \|^2 \leq 4R_3 \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(r, s) = n} \nu \| \nabla_r f \|^2 + 4R_3 \sum_{n=2}^{\infty} J^{n-2} \sum_{r: \text{dist}(r, i) = n} \nu \| \nabla_r f \|^2
\]
(5.24)

From (5.22)-(5.24) we get the following bound for the terms for $n = 2$ on the sum of (5.19)
\[
R_3 J^2 \sum_{s: \text{dist}(s, i_{23}) = 2} \nu \| \nabla_s (E_i f^2)^{\frac{1}{2}} \|^2 \leq R_3 J^2 \sum_{s: \text{dist}(s, i) = 2, 4} \nu \| \nabla_s f \|^2 + 4R_3 J^2 \sum_{n=2}^{\infty} J^n \sum_{r: \text{dist}(r, i) = n} \nu \| \nabla_r f \|^2 + 4R_3 \sum_{n=0}^{1} J^n \sum_{r: \text{dist}(r, i) = n} \nu \| \nabla_r f \|^2
\]
(5.25)
For every $s : dist(s, i_3) \geq 3$ we have $\nu \| \nabla_s (E_i f^2)^{\frac{1}{2}} \|^2 \leq \nu \| \nabla_s f \|^2$, which gives
\[
\sum_{n=3}^{\infty} J_n \sum_{r : dist(s, i_2) = n} \nu \| \nabla_s (E_i f^2)^{\frac{1}{2}} \|^2 \leq \sum_{n=3}^{\infty} J_n \sum_{r : dist(s, i_2) = n} \nu \| \nabla_s f \|^2 \leq 
(5.26)
\]
\[
\sum_{n=3}^{\infty} J_n^{n-2} \sum_{r : dist(s, i) = n} \nu \| \nabla_s f \|^2
\]
since $dist(i_{23}, i) = 2$.

Putting (5.20), (5.21), (5.25) and (5.26) in (5.19) leads to
\[
\nu \| \nabla_{i_{23}} (E^{(i_2, i_3, i_4)} f^2)^{\frac{1}{2}} \|^2 \leq \nu \| \nabla_{i_{23}} (E^{(i_2, i_3)} f^2)^{\frac{1}{2}} \|^2 \leq J R_4 \nu \| \nabla_i f \|^2 + J R_4 \sum_{r \cdot dist(s, i) = 1} \nu \| \nabla_s f \|^2 +
(5.27)
\]
for $R_4 = 2R_3 + 5R_3^2$. The exact same bound can be obtained for the other term on the first sum of the right hand side of (5.17). Gathering together, (5.17), (5.18) and (5.19) leads to
\[
\sum_{dist(r, i) = 2} \nu \| \nabla_r (E^{(i_2, i_3, i_4)} f^2)^{\frac{1}{2}} \|^2 \leq J R_5 \nu \| \nabla_i f \|^2 + J R_5 \sum_{r \cdot dist(s, i) = 1} \nu \| \nabla_s f \|^2 +
(5.28)
\]
for $R_5 = 8R_3 + R_4$.

Furthermore, for every $r : dist(r, i) \geq 3$,
\[
(5.29)
\]
Finally, if we put (5.16) and (5.28) and (5.29) in (5.15) we obtain
\[
\nu \| \nabla_i (E^{(\sim i)} f^2)^{\frac{1}{2}} \|^2 = \nu \| \nabla_i (E^{(i_1, i_2, i_3, i_4)} f^2)^{\frac{1}{2}} \|^2 \leq R_3 \nu \| \nabla_i (E^{(i_2, i_3, i_4)} f^2)^{\frac{1}{2}} \|^2 + R_6 \sum_{n=0}^{\infty} J_n \sum_{r \cdot dist(s, i) = n} \nu \| \nabla_s f \|^2
(5.30)
\]
for constant $R_6 = R_3 + R_3 R_5$.

If we repeat the same calculation recursively, for the first term on the right hand side of (5.30), then for $\nu \| \nabla_i (E^{(i_3, i_4)} f^2)^{\frac{1}{2}} \|^2$ and $\nu \| \nabla_i (E^{(i_4)} f^2)^{\frac{1}{2}} \|^2$ we will finally obtain
\[
\nu \| \nabla_i (E^{(\sim i)} f^2)^{\frac{1}{2}} \|^2 \leq R_6 \sum_{n=3}^{\infty} J_n \sum_{r \cdot dist(s, i) = n} \nu \| \nabla_s f \|^2
\]
for a constant $R_6$. From the last inequality and (5.14) we get
\[
\nu \| \nabla_i (E^{(\sim i)} f^2)^{\frac{1}{2}} \|^2 \leq C_1 \nu \| \nabla_i f \|^2 + C_2 \nu \| \nabla_s f \|^2
\]
for a constant $C_2 \leq JR_6(\sum_{k=0}^{\infty} (4J)^k) \leq \frac{JR_6}{4k^2}$ for $J$ sufficiently small such that $J < \frac{1}{4}$ and $J < \frac{1}{R_6-1}$ the proof of the proposition follows for $C_2 < 1$. 
\[\square\]

6. Log-Sobolev Type Inequalities.

Since the purpose of this paper is to prove the log-Sobolev inequality for the infinite dimensional Gibbs measure without assuming the log-Sobolev inequality for the one site measure $\mathbb{E}^i,\omega$, but the weaker inequality for the measure $\mu(dx_i) = e^{\phi(x_i)}dx_i$, we will show in this section that when the interactions are quadratic we can obtain a weaker log-Sobolev type inequality for the $\mathbb{E}^i,\omega$ measure. This will be the object of the next proposition.

**Proposition 6.1.** Assume that the measure $\mu$ satisfies the log-Sobolev inequality and that the local specification has quadratic interactions $V$ as in (2.1). Then, for $J$ sufficiently small, the one site measure $\mathbb{E}^i,\omega$ satisfies the following log-Sobolev type inequality

$$\nu \mathbb{E}^i,\omega \left(f^2 \log \frac{f^2}{\mathbb{E}^i,\omega f^2}\right) \leq c_1 \nu \|\nabla_i f\|^2 + c_1 \sum_{n=1}^{\infty} J^{n-1} \sum_{r, \text{dist}(r,i)=n} \nu(\|\nabla_r f\|^2)$$

for some positive constant $c_1$.

**Proof.** Assume $g \geq 0$. We start with our main assumption that the measure $\mu(dx) = e^{\phi(x)/\mu g^2}dx$ satisfies the log-Sobolev inequality for a constant $c_0$, that is

$$\mu(g^2 \log \frac{g^2}{\mu g^2}) \leq c_0 \mu \|\nabla_i g\|^2$$

(6.1)

We will interpolate this inequality to create the entropy with respect to the one site measure $\mathbb{E}^i,\omega$ in the left hand side. For this we will first define the function

$$V^i = \sum_{j \sim i} J_{i,j} V(x_i, \omega_j)$$

Notice that $V^i \geq 0$. Then inequality (6.1) for $g = e^{-V^i} f$, $f \geq 0$ gives

$$\int e^{-\phi(x_i)}(e^{-V^i} f^2 \log \frac{e^{-V^i} f^2}{\int e^{-\phi(x_i)}(e^{-V^i} f^2)dx_i})dx_i$$

$$\leq c_0 \int e^{-\phi(x_i)} \|\nabla_i (e^{-V^i} f)\|^2 dx_i$$

(6.2)

Denote by $S_r$ and $S_l$ the right and left hand side of (6.2) respectively. If we use the Leibnitz rule for the gradient on the right hand side of (6.2) we have

$$S_r \leq 2c_0 \int e^{-\phi(x_i)} \|\frac{e^{-V^i}}{\nabla_i f}\|^2 dx_i + 2c_0 \int e^{-\phi(x_i)} \|f(\nabla_i e^{-V^i}/f)\|^2 dx_i =$$

$$\left(\int e^{-\phi(x_i)} \nu \mathbb{E}^i,\omega \|\nabla_i f\|^2 + \frac{1}{4} \mathbb{E}^i,\omega f^2 \|\nabla_i V^i\|^2\right)$$

(6.3)
On the left hand side of (6.2) we form the entropy for the measure $\mathbb{E}^{i,\omega}$ measure with Hamiltonian $\phi(x_i) + V^i$.

$$S_i = \int e^{-\phi(x_i)-V^i} f^2 \log \frac{f^2}{\int e^{-\phi(x_i)-V^i} f^2 dx_i} dx_i$$

$$+ \int e^{-\phi(x_i)-V^i} f^2 \log \frac{\int e^{-\phi(x_i)} dx_i e^{-V^i}}{\int e^{-\phi(x_i)-V^i} dx_i} dx_i$$

$$= (\int e^{-\phi(x_i)-V^i} f^2 dx_i) \left( \mathbb{E}^{i,\omega}(f^2 \log \frac{f^2}{\mathbb{E}^{i,\omega} f^2}) - \mathbb{E}^{i,\omega}(f^2 V^i) \right)$$

$$+ \int e^{-\phi(x_i)-V^i} f^2 \log \frac{\int e^{-\phi(x_i)} dx_i}{\int e^{-\phi(x_i)-V^i} dx_i} dx_i$$

Since $V^i$ is no negative, the last equality leads to

$$S_i \geq \left( \int e^{-\phi(x_i)-V^i} f^2 dx_i \right) \left( \mathbb{E}^{i,\omega}(f^2 \log \frac{f^2}{\mathbb{E}^{i,\omega} f^2}) - \mathbb{E}^{i,\omega}(f^2 V^i) \right)$$

If we combine (6.2) together with (6.3) and (6.4) we obtain

$$\mathbb{E}^{i,\omega}(f^2 \log \frac{f^2}{\mathbb{E}^{i,\omega} f^2}) \leq 2c_0 \mathbb{E}^{i,\omega} \| \nabla f \|^2 + \mathbb{E}^{i,\omega}(f^2 \left( \frac{c_0 \| \nabla V^i \|^2}{2} + V^i \right))$$

If take the expectation with respect to the Gibbs measure in the last relationship we have

$$\nu(f^2 \log \frac{f^2}{\mathbb{E}^{i,\omega} f^2}) \leq 2c_0 \nu \| \nabla f \|^2 + \nu(f^2 \left( \frac{c_0 \| \nabla V^i \|^2}{2} + V^i \right))$$

From [B-Z] and [R] the following estimate of the entropy holds

$$\mathbb{E}^{i,\omega}(f^2 \log \frac{f^2}{\mathbb{E}^{i,\omega} f^2}) \leq A \mathbb{E}^{i,\omega}(f - \mathbb{E}^{i,\omega} f)^2 + \mathbb{E}^{i,\omega}(f - \mathbb{E}^{i,\omega} f)^2 \log \left( \frac{(f - \mathbb{E}^{i,\omega} f)^2}{\mathbb{E}^{i,\omega}(f - \mathbb{E}^{i,\omega} f)^2} \right)$$

for some positive constant $A$. If we take expectations with respect to the Gibbs measure at the last inequality we get

$$\nu(\| f \|^2 \log \frac{\| f \|^2}{\mathbb{E}^{i,\omega} f^2}) \leq A \nu |f - \mathbb{E}^{i,\omega} f|^2 + \nu(\| f - \mathbb{E}^{i,\omega} f \|^2 \log \frac{|f - \mathbb{E}^{i,\omega} f|^2}{\mathbb{E}^{i,\omega} |f - \mathbb{E}^{i,\omega} f|^2})$$

We can now use (6.5) to bound the second term on the right hand side of (6.7). Then we will obtain

$$\nu(f^2 \log \frac{f^2}{\mathbb{E}^{i,\omega} f^2}) \leq A \nu |f - \mathbb{E}^{i,\omega} f|^2 + 2c_0 \nu \| \nabla f \|^2 + \nu(\| f - \mathbb{E}^{i,\omega} f \|^2 \left( \frac{c_0 \| \nabla V^i \|^2}{2} + V^i \right)) \leq$$

$$A \nu |f - \mathbb{E}^{i,\omega} f|^2 + 2c_0 \nu \| \nabla f \|^2 + \sum_{j=1}^n J_{i,j} \nu(\| f - \mathbb{E}^{i,\omega} f \|^2 \left( \frac{c_0 \| \nabla V(x_i, \omega_j) \|^2}{2} + V(x_i, \omega_j) \right))$$
If we take under account that we are considering quadratic interactions and bound $V$ and $\|\nabla_i V^i\|^2$ by \([2.1]\) we get

$$\nu(f^2 \log \frac{f^2}{\mathbb{E}^i f^2}) \leq (A + 4) \nu |f - \mathbb{E}^i f|^2 + 2c_0 \nu \|\nabla_i f\|^2 + 4(2c_0 + 1) k J \nu (|f - \mathbb{E}^i f|^2 d^2(x_i)) + (2c_0 + 1) k J \sum_{j \sim i} \nu(|f - \mathbb{E}^i f|^2 d^2(\omega_j))$$

where above we also used that $V(x_i, \omega_j) \leq 1 + |V(x_i, \omega_j)|^2$. We can bound the first term on the right hand side by Lemma \([4.3]\) and the third and the fourth term by Corollary \([4.6]\)

$$\nu(f^2 \log \frac{f^2}{\mathbb{E}^i f^2}) \leq c_1 \nu \|\nabla_i f\|^2 + c_1 \sum_{n=1}^{\infty} J^n \sum_{r: \text{dist}(r, i) = n} \nu(\|\nabla_r f\|^2)$$

which finishes the proof of the proposition for $c_1 = (A+4)4(D_L+D_3) + 6(2c_0+1)kD_5$. \(\square\)

We now prove a log-Sobolev type inequality for the product measure $\mathbb{E}^{\Gamma_k}$ for $k = 0, 1$.

**Proposition 6.2.** Assume that the measure $\mu$ satisfies the log-Sobolev inequality and that the local specification has quadratic interactions $V$ as in \([2.7]\). Then, for $J$ sufficiently small, the following log-Sobolev type inequality for the product measures $\mathbb{E}^{\Gamma_k}$ holds

$$\nu\mathbb{E}^{\Gamma_k}(f^2 \log \frac{f^2}{\mathbb{E}^{\Gamma_k} f^2}) \leq \tilde{C} \nu \|\nabla_{\Gamma_0} f\|^2 + \tilde{C} \nu \|\nabla_{\Gamma_1} f\|^2$$

for $k = 0, 1$, and some positive constant $\tilde{C}$.

**Proof.** We will prove Proposition 6.2 for $k = 1$, that is

$$\nu\mathbb{E}^{\Gamma_1}(f^2 \log \frac{f^2}{\mathbb{E}^{\Gamma_1} f^2}) \leq \tilde{C} \nu \|\nabla_{\Gamma_0} f\|^2 + \tilde{C} \nu \|\nabla_{\Gamma_1} f\|^2$$

for $f \geq 0$.

In the proof of this proposition we will use the following estimation. For any $i \in \mathbb{Z}$ and $\{\sim i\} = i_1, i_2, i_3, i_4$ denote

$$\Theta(i) := \nu \|\nabla_i (\mathbb{E}^{\{i_1, i_2, i_3, i_4\}} f^2)^{\frac{1}{2}}\|^2 + \nu \|\nabla_i (\mathbb{E}^{\{i_2, i_3, i_4\}} f^2)^{\frac{1}{2}}\|^2 + \nu \|\nabla_i (\mathbb{E}^{\{i_3, i_4\}} f^2)^{\frac{1}{2}}\|^2 + \nu \|\nabla_i (\mathbb{E}^{\{i_4\}} f^2)^{\frac{1}{2}}\|^2$$

and

$$\Lambda(i) := \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(s, i) = n} \nu \|\nabla_s f\|^2$$

From the calculations of the components of the sum of $\Theta(i)$ in the proof of Proposition 5.3 and the recursive inequality \([5.30]\) we can surmise that there exists an $R_7 > 0$ such that

$$\Theta(i) \leq R_7 \Lambda(i)$$

We start with the following enumeration of the nodes in $\Gamma_1$ as depicted in figure 2. Denote the nodes in $\Gamma_1$ closest to $(0, 0)$, that is the neighbors of $(0, 0)$ and name them $a_1, a_2, a_3, a_4$, with $a_1$ being any of the four and the rest named clockwise. Then choose
any of the nodes in $\Gamma_1$ of distance two from $a_4$ and distance three from $(0,0)$, and name it $a_5$ and continue clockwise the enumeration with the rest of the nodes in $\Gamma_1$ of distance three form $(0,0)$. Then the same for the nodes of $\Gamma_1$ of distance four from $(0,0)$. We continue with the same way with the nodes in $\Gamma_1$ of higher distances from $(0,0)$, moving clockwise while we move away from $(0,0)$. In this way the nodes in $\Gamma_1$ are enumerated in a spiral way moving clockwise away from $(0,0)$. In that way we can write $\mathbb{E}^{\Gamma_1} = \cap_{i=1}^{+\infty} \mathbb{E}^{a_i}$.

Then the entropy of the product measure $\mathbb{E}^{\Gamma_1}$ can be calculated by being expressed in terms of the entropies of single nodes in $\Gamma_1$ for which we have shown a log-Sobolev type inequality in Proposition 6.1.

(6.9) $\nu \mathbb{E}^{\Gamma_1}(f^2 \log \frac{f^2}{\mathbb{E}^{\Gamma_1} f^2}) = \sum_{k=1}^{+\infty} \nu \mathbb{E}^{a_k}(\mathbb{E}^{a_{k-1}}...\mathbb{E}^{a_1} f^2 \log \frac{\mathbb{E}^{a_{k-1}}...\mathbb{E}^{a_1} f^2}{\mathbb{E}^{a_k}...\mathbb{E}^{a_1} f^2})$

To compute the entropies in the right hand side of (6.9) we will use the log-Sobolev type inequality for the one site measure $\mathbb{E}^k$ from Proposition 6.1.

(6.10) $\nu \mathbb{E}^k(\mathbb{E}^{a_{k-1}}...\mathbb{E}^{a_1} f^2 \log \frac{\mathbb{E}^{a_{k-1}}...\mathbb{E}^{a_1} f^2}{\mathbb{E}^{a_k}...\mathbb{E}^{a_1} f^2}) \leq c_1 \nu \|\nabla f\|^2 + c_1 \sum_{n=1}^{+\infty} J^{n-1} \sum_{j: \text{dist}(j,a_k) = n} \nu \|\nabla_j (\mathbb{E}^{a_{k-1}}...\mathbb{E}^{a_1} f^2)^{\frac{1}{2}}\|^2$

where above we used that $\nu \|\nabla_{a_k}(\mathbb{E}^{a_{k-1}}...\mathbb{E}^{a_1} f^2)^{\frac{1}{2}}\|^2 \leq \nu \|\nabla_{a_k} f\|^2$, since by the way the spiral was constructed it’s elements do not neighbour with each other. For every $j$ that neighbours with at least one of the $a_{k-1}, a_{k-2},..., a_1$ we have that

$\nu \|\nabla_j (\mathbb{E}^{a_{k-1}}...\mathbb{E}^{a_1} f^2)^{\frac{1}{2}}\|^2 \leq \Theta(j)$

which because of (6.8) implies

(6.11) $\nu \|\nabla_j (\mathbb{E}^{a_{k-1}}...\mathbb{E}^{a_1} f^2)^{\frac{1}{2}}\|^2 \leq R_7 \Lambda(j)$
For every $j$ that does not neighbour with any of the $a_{k-1}, a_{k-2}, \ldots, a_1$ we have that
\begin{equation}
\nu \| \nabla_j (E^{a_{k-1}} \cdots E^{a_1} f^2) \|^2 \leq \nu \| \nabla f \|^2
\end{equation}

Putting \eqref{eq:6.11} and \eqref{eq:6.12} in \eqref{eq:6.10} we obtain
\[ \nu E^{a_k} (E^{a_{k-1}} \cdots E^{a_1} f^2 \log E^{a_{k-1}} \cdots E^{a_1} f^2) \leq c_1 \nu \| \nabla_{a_k} f \|^2 + c_1 R_7 \sum_{n=1}^{\infty} J^{n-1} \sum_{j: \text{dist}(j, a_k) = n} \Lambda(j) + c_1 \sum_{n=1}^{\infty} J^{n-1} \sum_{j: \text{dist}(j, a_k) = n} \nu \| \nabla_j f \|^2 \]

Combining this with \eqref{eq:6.9}
\[ \nu E^{\Gamma_1} (f^2 \log E^{f^2}) \leq c_1 \sum_{k=1}^{+\infty} \nu \| \nabla_{a_k} f \|^2 + c_1 R_7 \sum_{k=1}^{+\infty} \sum_{n=1}^{\infty} J^{n-1} \sum_{j: \text{dist}(j, a_k) = n} \Lambda(j) + c_1 \sum_{k=1}^{+\infty} \sum_{n=1}^{\infty} J^{n-1} \sum_{j: \text{dist}(j, a_k) = n} \nu \| \nabla_j f \|^2 \]

Since in the last two sums above, for every $j \in \mathbb{Z}^2$, the terms $\Lambda(j)$ and $\nu \| \nabla_j f \|^2$ appear one time for every $i \in \Gamma_1$ with a coefficient $J^{\text{dist}(i, j)-1}$, the accompanying coefficient for any of these terms is $\sum_{k=0}^{\infty} (4J)^k$ since for every node $j$, $\# \{ i : \text{dist}(i, j) = n \} \leq 4^n$. So by rearranging the terms in the last inequality we get
\[ \nu E^{\Gamma_1} (f^2 \log E^{f^2}) \leq c_1 \nu \| \nabla_{\Gamma_1} f \|^2 + \frac{R_7 c_1}{J} \sum_{j \in \mathbb{Z}^2} \left( \sum_{n=0}^{\infty} (4J)^n \right) \Lambda(j) + \frac{R_7 c_1}{J} \sum_{j \in \mathbb{Z}^2} (4J)^n \nu \| \nabla_j f \|^2 \]
\[ = c_1 \nu \| \nabla_{\Gamma_1} f \|^2 + \frac{R_7 c_1}{J(1-4J)} \sum_{j \in \mathbb{Z}^2} \Lambda(j) + \frac{R_7 c_1}{J(1-4J)} \sum_{j \in \mathbb{Z}^2} \nu \| \nabla_j f \|^2 \]

for $J < \frac{1}{4}$. For the first sum
\[ \sum_{j \in \mathbb{Z}^2} \Lambda(j) = \sum_{j \in \mathbb{Z}^2} \sum_{n=0}^{\infty} J^n \sum_{r: \text{dist}(s, j) = n} \nu \| \nabla_s f \|^2 \leq \sum_{j \in \mathbb{Z}^2} \left( \sum_{n=0}^{\infty} (4J)^n \right) \nu \| \nabla_j f \|^2 \]
\[ = \frac{1}{1-4J} \sum_{j \in \mathbb{Z}^2} \nu \| \nabla_j f \|^2 \]
We finally get
\[ \nu E_{\Gamma_i}(f^2 \log \frac{f^2}{E_{\Gamma_1} f^2}) \leq c_1 \nu \| \nabla_{\Gamma_1} f \|^2 + \frac{2R_1 c_1}{J(1 - 4J)^2} \sum_{j \in \mathbb{Z}} \nu \| \nabla_j f \|^2. \]

7. Spectral Gap and Proof of Main Theorem

In Proposition 6.1 and Proposition 6.2 we showed a log-Sobolev type inequality for the one site measure \( E^{i,\omega} \) and then obtained a similar inequality through it for the product measures \( E^{\Gamma_i,\omega} \). In Lemma 4.5 a spectral gap type inequality was also shown for the one site measure \( E^{i,\omega} \) for both cases. In the following proposition the spectral gap type inequality of Lemma 4.5 will be extended to the product measure \( E^{\Gamma_i,\omega} \).

However, this does not happen through the Spectral Gap type inequality for the one site measure \( E^{i,\omega} \) of Lemma 4.5 but through the log-Sobolev type inequality for \( E^{\Gamma_i,\omega}, i = 0, 1 \) of Proposition 6.2.

Proposition 7.1. Assume that the measure \( \mu \) satisfies the log-Sobolev inequality and that the local specification has quadratic interactions \( V \) as in (2.1). Then, for \( J \) sufficiently small, the following spectral gap type inequality holds
\[ \nu |f - E^{\Gamma_i,\omega} f|^2 \leq \tilde{R} \nu \| \nabla_{\Gamma_0} f \|^2 + \tilde{R} \nu \| \nabla_{\Gamma_1} f \|^2 \]
for \( i = 0, 1 \) and some positive constant \( \tilde{R} \).

The proof of this proposition is based in the use of the log-Sobolev type inequality for the product measures \( E^{\Gamma_i,\omega}, i = 0, 1 \) of Proposition 6.2 and the sweeping out relations for the same measures from Proposition 4.8. The proof of this proposition is presented in Lemma 7.1 of [Pa1].

Spectral Gap inequalities have been associated with convergence to equilibrium and ergodic properties. In the next proposition we will use the weaker spectral gap inequality for the product measures \( E^{\Gamma_i,\omega}, i = 0, 1 \) of Proposition 7.1 to show the a.e. convergence of \( P^n \) to the infinite dimensional Gibbs measure \( \nu \), where \( P^n \) is defined as follows
\[ P^n f = \begin{cases} f & n = 0 \\ E_{\Gamma_0}P^{n-1} f & n \text{ odd} \\ E_{\Gamma_1}P^{n-1} f & n \text{ even} > 0 \end{cases} \]

Proposition 7.2. Assume that the measure \( \mu \) satisfies the log-Sobolev inequality and that the local specification has quadratic interactions \( V \) as in (2.1). Then, for \( J \) sufficiently small, and \( P \) as in (7.1), \( P^n f \) converges \( \nu \)-a.e. to the Gibbs measure \( \nu \).

Proof. We will follow closely [G-Z]. We will compute the variance of the \( P^n f \) with respect to the product measure \( E^{\Gamma_k} \) for \( k = 0 \) or \( 1 \) when \( n \) is odd or even respectively. For this we will use the spectral gap type inequality for the product measures \( E^{\Gamma_i,\omega}, i = 0, 1 \) presented in Proposition 7.1.

\[ \nu |P^n f - P^{n+1} f|^2 = \nu |P^n f - E^{\Gamma_k}P^n f|^2 \leq \tilde{R} \nu \| \nabla_{\Gamma_k} P^n f \|^2 + \tilde{R} \nu \| \nabla_{\Gamma_1} P^n f \|^2 = \tilde{R} \nu \| \nabla_{\Gamma_k} P^n f \|^2 = \tilde{R} \nu \| \nabla_{\Gamma_1} P^{n-1} f \|^2 \]
where \( k \) above is 0 or 1 if \( n \) is odd or even respectively. If we use the first sweeping out inequality of Proposition \( 4.8 \) we get
\[
\nu |\mathcal{P}^n f - \mathcal{P}^{n+1} f|^2 \leq R_1 \nu \| \nabla_{\Gamma_1} \mathcal{P}^{n-1} f \|^2 + R_2 \nu \| \nabla_{\Gamma_{1-k}} \mathcal{P}^{n-1} f \|^2 = R R_2 \nu \| \nabla_{\Gamma_{1-k}} \mathcal{P}^{n-1} f \|^2
\]
where we recall \( R_2 \leq \frac{J G_6}{4 R} < 1 \). If we apply \( n - 2 \) more times Proposition \( 4.8 \) we obtain the following bound
\[
(7.2) \quad \nu |\mathcal{P}^n f - \mathcal{P}^{n+1} f|^2 \leq R R_2^{n-2} \left( R_1 \nu \| \nabla_{\Gamma_1} f \|^2 + R_2 \nu \| \nabla_{\Gamma_0} f \|^2 \right)
\]
which converges to zero as \( n \) goes to infinity, because \( R_2 < 1 \). If we define the sets
\[
\Delta_n = \{|\mathcal{P}^n f - \mathcal{P}^{n+1} f| \geq \frac{1}{2^n}\}
\]
we can calculate
\[
\nu(\Delta_n) = \nu \left( \left\{|\mathcal{P}^n f - \mathcal{P}^{n+1} f| \geq \frac{1}{2^n}\} \right\} \leq 2^{2n} \nu |\mathcal{P}^n f - \mathcal{P}^{n+1} f|^2
\]
by Chebyshev inequality. If we use \( (7.2) \) to bound the last one we get
\[
\nu(\Delta_n) \leq (4 R_2)^{n-2} 64 \hat{R} \left( R_1 \nu \| \nabla_{\Gamma_1} f \|^2 + R_2 \nu \| \nabla_{\Gamma_0} f \|^2 \right)
\]
and for \( J \) sufficiently small such that \( 4 R_2 \leq \frac{J G_6}{4 R} < \frac{1}{2} \) (recall that \( R_2 \leq \frac{J G_6}{4 R} \)) we have that
\[
\sum_{n=0}^{\infty} \nu(\Delta_n) \leq \sum_{n=0}^{\infty} \frac{1}{2^n} \cdot 64 \hat{R} \left( R_1 \nu \| \nabla_{\Gamma_1} f \|^2 + R_2 \nu \| \nabla_{\Gamma_0} f \|^2 \right) < \infty
\]
Thus,
\[
\{\mathcal{P}^n f - \nu \mathcal{P}^n f\}_{n \in \mathbb{N}}
\]
converges \( \nu \)-almost surely by the Borel-Cantelli lemma. Furthermore,
\[
\mathcal{P}^n f \rightarrow \vartheta(f) \quad \nu - a.e.
\]
We will first show that \( \vartheta(f) \) is a constant, which means that it does not depend on variables on \( \Gamma_0 \) or \( \Gamma_1 \). We first notice that \( \mathcal{P}^n f \) is a function on \( \Gamma_0 \) or \( \Gamma_1 \) when \( n \) is odd or even respectively. This implies that the limits
\[
\vartheta_o(f) := \lim_{n \text{ odd}, n \rightarrow \infty} \mathcal{P}^n f \quad \text{and} \quad \vartheta_e(f) := \lim_{n \text{ even}, n \rightarrow \infty} \mathcal{P}^n f
\]
do not depend on variables on \( \Gamma_0 \) and \( \Gamma_1 \) respectively. However, since the two subsequences \( \{\mathcal{P}^n f\}_{n \text{ even}} \) and \( \{\mathcal{P}^n f\}_{n \text{ odd}} \) converge to \( \vartheta(f) \) \( \nu \)-a.e. we conclude that
\[
\vartheta_o(f) = \vartheta(f) = \vartheta_e(f)
\]
which implies that \( \theta(f) \) is a constant. From that we obtain that
\[
(7.3) \quad \nu(\vartheta(f)) = \vartheta(f)
\]
Since the sequence \( \{\mathcal{P}^n f\}_{n \in \mathbb{N}} \) converges \( \nu \)-almost, the same holds for the sequence \( \{\mathcal{P}^n f - \nu \mathcal{P}^n f\}_{n \in \mathbb{N}} \).

It remains to show that \( \vartheta(f) = \nu(f) \). At first we show this for positive bounded functions \( f \). In this case we have
\[
(7.4) \quad \lim_{n \rightarrow \infty} (\mathcal{P}^n f - \nu \mathcal{P}^n f) = \vartheta(f) - \nu(\vartheta(f)) = \vartheta(f) - \vartheta(f) = 0
\]
by the dominated convergence theorem and (7.3). On the other hand, we also have
\[ \lim_{n \to \infty} (\mathcal{P}^n f - \nu \mathcal{P}^n f) = \lim_{n \to \infty} (\mathcal{P}^n f - \nu f) = \vartheta(f) - \nu(f) \]
where above we used the definition of the Gibbs measure \( \nu \). From (7.4) and (7.5) we get that
\[ \vartheta(f) = \nu(f) \]
for bounded functions \( f \). We now extend it to no bounded positive functions \( f \). Consider \( f_k(x) := \max\{f(x), k\} \) for any \( k \in \mathbb{N} \). Then
\[ \vartheta(f_k) = \lim_{n \to \infty} \mathcal{P}^n f_k = \nu f_k, \quad \nu \text{ a.e.} \]
since \( f_k(x) \) is bounded by \( k \). Then since \( f_k \) is increasing on \( k \), by the monotone convergence theorem we obtain
\[ \vartheta(f) = \lim_{k \to \infty} \vartheta(f_k) = \lim_{k \to \infty} \nu(f_k) = \nu(f) \quad \nu \text{ a.e.} \]
The assertions then can be extended to no positive functions \( f \) by writing \( f = f^+ - f^- \), where \( f^+ = \max\{f, 0\} \) and \( f^- = -\min\{f, 0\} \).

We can now proceed with the proof of the main theorem.

7.1. **proof Proposition 2.3.** The proof of the main result will be based on the iterative method developed by Zegarlinski in [Z1] and [Z2] (see also [Pa1] and [I-P] for similar application). We will start with a lemma that shows the iterative step.

Denote \( \text{Ent}_\mu(f) := \mu(f^2 \log f^2 \mu f^2) \) the entropy of a function \( f \) with respect to a measure \( \mu \).

**Lemma 7.3.** Assume \( \mathcal{P} \) as in (7.1). For any \( n \geq 1 \),
\[ \mathcal{P}^n[f \log f] = \sum_{m=0}^{n-1} \mathcal{P}^{n-m-1}[\text{Ent}_{\mathcal{E}^{\Gamma_k}}(\mathcal{P}^m f)] + \mathcal{P}^n f \log \mathcal{P}^n f \]
where \( k \) above is 0 or 1 if \( n \) is odd or even respectively.

**Proof.** One observes that for any \( \Lambda \subset \mathbb{Z}^2 \)
\[ \text{Ent}_{\mathcal{E}_\Lambda}(g) = \mathbb{E}_\Lambda \left( g \log \frac{g}{\mathbb{E}_\Lambda g} \right) = \mathbb{E}_\Lambda [g \log g] - (\mathbb{E}_\Lambda g) \log(\mathbb{E}_\Lambda g) \]
The statement (7.6) for \( n = 1 \) can be trivially derived from (7.7) if we put \( \Lambda = \Gamma_0 \) and \( g = f \). Assuming (7.6) is true for some \( n \geq 0 \), we prove it for \( n + 1 \). Apply (7.7) with \( \Lambda = \Gamma_k \) and \( \mathcal{P}^n f \) in the place of \( g \), where \( k \) above is 0 or 1 if \( n \) is odd or even respectively:
\[ \mathbb{E}_{\Gamma_k}[\mathcal{P}^n f \log(\mathcal{P}^n f)] = \text{Ent}_{\mathcal{E}^{\Gamma_k}}(\mathcal{P}^n f) + (\mathbb{E}_{\Gamma_k}^{\mathcal{E}^{\Gamma_k}} \mathcal{P}^n f) \log(\mathbb{E}_{\Gamma_k}^{\mathcal{E}^{\Gamma_k}} \mathcal{P}^n f) \]
\[ = \text{Ent}_{\mathcal{E}^{\Gamma_k}}(\mathcal{P}^n f) + (\mathcal{P}^{n+1} f) \log(\mathcal{P}^{n+1} f) \]
Using this, and applying \( \mathbb{E}_{\Gamma_k}^{\mathcal{E}^{\Gamma_k}} \) to (7.6) we obtain (7.6) for \( n + 1 \). \( \square \)
Using Proposition 7.2 we have \( P_n[f \log f] \to \nu[f \log f] \) and \( \nu(P^n f) \to \nu[f] \log \nu[f] \), \( \nu \)-a.e. From this and Fatou’s lemma, (7.6) gives

\[
\text{Ent}_\nu(f^2) \leq \liminf_{n \to \infty} \left\{ \nu \left[ \sum_{m=0}^{n-1} P_{n-m-1} \text{Ent}_{E \Gamma_k}(P^m f) \right] \right\}
\]

(7.8)

where we used the fact that \( \nu \) is a Gibbs measure to obtain the last equality. If we use Proposition 6.2 to bound the first term of the first sum we have

\[
\nu \text{Ent}_{E \Gamma_0}(f^2) \leq \tilde{C} \nu \| \nabla \Gamma_0 f \|^2 + \tilde{C} \nu \| \nabla \Gamma_1 f \|^2
\]

Similarly, for \( m \geq 1 \), we can use Proposition 6.2 and then we get

\[
\nu \text{Ent}_{E \Gamma_k}(P^m f^2) \leq \tilde{C} \nu \| \nabla \Gamma_k \sqrt{P^m f^2} \|^2 \leq \tilde{C} [C_1 C_2^{m-1} \nu \| \nabla \Gamma_1 f \|^2 + C_2^m \nu \| \nabla \Gamma_0 f \|^2]
\]

where, for the last inequalities we used Proposition 5.3 and induction. Substituting in (7.8), we obtain (recall that \( 0 \leq C_2 < 1 \))

\[
\text{Ent}_\nu(f^2) \leq \frac{\tilde{C} C_1}{C_2(1-C_2)} \nu \| \nabla \Gamma_1 f \|^2 + \frac{\tilde{C}}{1-C_2} \nu \| \nabla \Gamma_0 f \|^2 \leq \overline{C} \nu \| f \|^2
\]

where \( \overline{C} \) is the largest of the two coefficients. This ends the proof of the log-Sobolev inequality for \( \nu \).

\[ \square \]
