SOCS3 deficiency in leptin receptor-expressing cells mitigates the development of pregnancy-induced metabolic changes

ABSTRACT

Objective: During pregnancy, women normally increase their food intake and body fat mass, and exhibit insulin resistance. However, an increasing number of women are developing metabolic imbalances during pregnancy, including excessive gestational weight gain and gestational diabetes mellitus. Despite the negative health impacts of pregnancy-induced metabolic imbalances, their molecular causes remain unclear. Therefore, the present study investigated the molecular mechanisms responsible for orchestrating the metabolic changes observed during pregnancy.

Methods: Initially, we investigated the hypothalamic expression of key genes that could influence the energy balance and glucose homeostasis during pregnancy. Based on these results, we generated a conditional knockout mouse that lacks the suppressor of cytokine signaling-3 (SOCS3) only in leptin receptor-expressing cells and studied these animals during pregnancy.

Results: Among several genes involved in leptin resistance, only SOCS3 was increased in the hypothalamus of pregnant mice. Remarkably, SOCS3 deletion from leptin receptor-expressing cells prevented pregnancy-induced hyperphagia, body fat accumulation as well as leptin and insulin resistance without affecting the ability of the females to carry their gestation to term. Additionally, we found that SOCS3 conditional deletion protected females against long-term postpartum fat retention and streptozotocin-induced gestational diabetes.

Conclusions: Our study identified the increased hypothalamic expression of SOCS3 as a key mechanism responsible for triggering pregnancy-induced leptin resistance and metabolic adaptations. These findings not only help to explain a common phenomenon of the mammalian physiology, but it may also aid in the development of approaches to prevent and treat gestational metabolic imbalances.

1. INTRODUCTION

The developing embryo and subsequent fetus impose energy demands on pregnant women. Consequently, increased food intake is expected during gestation [1,2]. Additionally, pregnancy leads to benign and transitory insulin resistance [3]. These metabolic adaptations are thought to have evolved to ensure better conditions for offspring development [2]. However, an increasing number of women are developing metabolic imbalances during pregnancy, including excessive gestational weight gain (EGWG) and gestational diabetes mellitus (GDM) [3,4]. These conditions represent a serious health threat to women and their offspring and are becoming a major obstetric complication worldwide. For example, EGWG increases the risk of maternal mortality, GDM, pre-eclampsia, thromboembolism, postpartum hemorrhage and other gestational complications [3]. Furthermore, long-term postpartum weight retention predisposes women to obesity, and GDM increases the risk of diabetes mellitus later in life [4]. Therefore, metabolic imbalances during pregnancy may also aggravate the obesity and diabetes epidemics. Despite the negative health impacts of pregnancy-induced metabolic imbalances, the precise mechanisms responsible for orchestrating these changes remain largely unknown. Previous studies have

reported lower responsiveness to leptin in pregnant animals \[5\text{–}\text{7}].

Nonetheless, no compelling evidence has been provided about the real contribution of leptin resistance for the onset of pregnancy-induced metabolic changes. Therefore, the objective of the present study was to identify key molecular mechanisms that trigger the metabolic changes observed during pregnancy.

2. MATERIAL AND METHODS

2.1. Generation of conditional knockout mice

All mouse strains were backcrossed at least 4 times to the C57BL/6 background before the initiation of breeding. To induce the Socs3 gene deletion exclusively in leptin-responsive cells, we bred the LepR-IRES-Cre strain (B6.129-Lep\(^{\text{tm3}(cre)Rck}\)/J, Jackson Laboratories) with mice carrying loxP-flanked Socs3 alleles (B6.129S4-Socs3\(^{\text{fl}X\text{amy}^{\text{P2}}}\)/J, Jackson Laboratories). The Socs3 KO group was composed of animals homozygous for the loxP-flanked Socs3 allele and homozygous for the LepR-IRES-Cre allele. The control group was composed of animals homozygous for the LepR-IRES-Cre allele. We used only littersmates as controls. The mice were weaned at 4 weeks of age, and the genomic DNA was extracted from tail tips for PCR genotyping (Sigma). The loxP-flanked Socs3 allele and the wild-type allele were identified by the presence of a 420 bp or 272 bp PCR fragment, respectively. The LepR-IRES-Cre allele and the wild-type allele were identified by the presence of a 213 bp or 800 bp PCR fragment, respectively. After weaning, the mice received a regular low-fat rodent diet (2.99 kcal/g; 9.4% calories from fat; Quimtia, Brazil). All animal procedures were approved by the Ethics Committee on the Use of Animals of the Institute of Biomedical Sciences at the University of São Paulo, São Paulo, Brazil.

2.2. Breeding strategy and tissue collection

Two-month-old females were bred with sexually experienced males, and we assessed the presence of copulatory plugs on a daily basis. The tissues were quickly dissected for relative gene expression analysis as previously described in Ref. [8]. Specific primers were designed for each target gene according to the sequences obtained from GenBank or acquired from Applied Biosystems (Supplemental Table 1). The data were reported as fold changes compared with the values obtained from the control group (set at 1.0).

2.3. Relative gene expression

The tissues were quickly dissected for relative gene expression analysis as previously described in Ref. [8]. Specific primers were designed for each target gene according to the sequences obtained from GenBank or acquired from Applied Biosystems (Supplemental Table 1). The data were reported as fold changes compared with the values obtained from the control group (set at 1.0).

2.4. Leptin sensitivity tests

For all experiments, we used mouse recombinant leptin purchased from Dr. A.F. Parlow (National Hormone and Peptide Program, National Institute of Diabetes and Digestive and Kidney Diseases). On P5, mice were anaesthetized (isoflurane) and we performed a surgical procedure, in which osmotic micro-pumps (model 1002; Alzet) were implanted s.c. to deliver 0.5 \(\mu\)g leptin/h. Body weight and food intake were measured daily before (P1–P5) and after (P6–P16) surgery. To determine the region-specific responses to leptin, pregnant control and Socs3 KO mice received a leptin injection after a 4 h fasting period (2.5 \(\mu\)g leptin/g; s.c.). Three hours later, the mice were perfused with 10% buffered formalin, and their brains were processed to detect leptin-induced phosphorylation of the Signal Transducer and Activator of Transcription 3-immunoreactive (pSTAT3-ir) as previously described in Ref. [7]. We counted the number of pSTAT3-ir cells on one side of a representative rostrocaudal level.

2.5. Western blot

The tissues were homogenized in RIPA buffer (Sigma) containing a cocktail of proteases and phosphatase inhibitors (1:100, Sigma). Protein (40 or 50 \(\mu\)g) was resolved on a 10% SDS-PAGE gel and transferred to a nitrocellulose membrane (Bio-Rad). The membranes were blocked with 5% BSA and incubated overnight at 4°C with primary antibodies (1:1,000; pSTAT3 \(^{\text{Y705}}\), Cell Signaling; STAT3, Santa Cruz; Socs3, Cell Signaling; pIR\(^{\text{Y1162/1163}}\), Santa Cruz; pAKT-\(^{\text{S473}}\), Cell Signaling; GAPDH, Santa Cruz). Next, the membranes were incubated for 45 min with secondary antibody (1:10,000; IRDye 800CW, LI-COR). The proteins were detected and analyzed using the LI-COR Odyssey system.

2.6. Hormone levels

ELISA kits were used to determine the serum concentrations of leptin (Crystal Chem), insulin (Crystal Chem) and glucagon (Sigma).

2.7. Glucose homeostasis

A glucose tolerance test (GTG; 2 g glucose/kg; s.c.) and an insulin tolerance test (ITT; 1 IU insulin/kg; s.c.) were performed on P14 and P16, respectively. Insulin sensitivity was evaluated in different tissues by infusing 5 IU insulin/kg s.c. into pregnant mice and euthanizing them 15 min after the injection. GDM was induced by a single intraperitoneal injection of freshly prepared streptozotocin (STZ; 200 mg/kg; Amresco) dissolved in 50 mM sodium citrate (pH 4.5) on P5 [9]. Glicemia was assessed before (on P1 and P4) and after (on P7 and P13) the STZ injection, followed by a GTT (0.5 g glucose/kg; s.c.) on P14.

2.8. Statistics

The results are expressed as mean ± SEM. The differences between the groups were compared using an unpaired two-tailed Student’s \(t\)-test. The data obtained from the leptin and insulin sensitivity tests were analyzed by two-way ANOVA and the Bonferroni post hoc test. Glycemic changes after the STZ treatment were assessed using repeated measures ANOVA. Statistical analyses were performed using GraphPad Prism software. We considered \(p\) values of less than 0.05 to be statistically significant.

3. RESULTS

3.1. Identification of proteins potentially related with leptin resistance during pregnancy

We investigated the hypothalamic expression of several genes potentially related to leptin resistance including components of the
suppressor of cytokine signaling (SOCS) family, adapter proteins such as SH2B1, protein-tyrosine phosphatases and LepR isoforms. Among them, only SOCS3 and Ob-Re expression were increased in the hypothalamus of pregnant mice (Figure 1A). Interestingly, SOCS3 is the main member of the SOCS family capable of inhibiting leptin receptor (LepR) signaling [10,11]. Its expression is increased in the hypothalamus of obese animals, and the brain-specific ablation of SOCS3 increases leptin sensitivity in diet-induced obesity (DIO) [12–15]. Therefore, SOCS3 is a strong candidate to induce both leptin resistance and the metabolic changes during pregnancy.

3.2. Generation of mice lacking SOCS3 only in LepR-expressing cells

Mice carrying LoxP-flanked Socs3 alleles were bred with animals expressing Cre recombinase under the Lepr promoter control (Figure 1B). Thus, SOCS3 was inactivated specifically in LepR-expressing cells (SOCS3 KO mice). Littermate mice carrying the wild-type Socs3 gene were used as controls. Both groups were composed of animals homozygous for the Cre allele (Figure 1B). To functionally confirm the genetic deletion, we assessed the capacity of an acute leptin injection to induce hypothalamic SOCS3 mRNA expression [10,11]. We found that leptin increased SOCS3 expression only in control animals (Figure 1C). Then, we compared hypothalamic SOCS3 expression in nulliparous and pregnant SOCS3 KO mice. In contrast to the elevated SOCS3 mRNA expression seen during pregnancy in wild-type mice (Figure 1A), pregnant SOCS3 KO mice did not show increased SOCS3 hypothalamic expression (Figure 1D). These results indicate that pregnancy-induced changes in hypothalamic SOCS3 expression are restricted to LepR-expressing cells. Gene expression analysis in the hypothalamus of pregnant mice confirmed that SOCS3 KO females did not exhibit compensatory alterations in the expression of other components potentially related to leptin resistance, although pregnant SOCS3 KO mice had a higher hypothalamic expression of Ob-Re compared to control animals (Supplemental Figure 1).

Because SOCS3 inhibits LepR signaling [10,11], SOCS3 KO mice are expected to be more responsive to leptin. To determine leptin sensitivity in the hypothalamus, non-pregnant control and SOCS3 KO mice received a leptin injection to induce pSTAT3. Leptin increased pSTAT3 expression 1.5 h after the injection. However, SOCS3 KO mice showed a longer and sustained increase in the pSTAT3 expression compared to control animals, indicating a prolonged signaling through the LepR (Figure 1E). Additionally, hypothalamic SOCS3 was increased in control mice 3 h after leptin injection, whereas no such changes were detected in SOCS3 KO mice (Figure 1E). These results confirm the efficiency of SOCS3 inactivation in LepR-responsive cells.

3.3. Metabolic changes during pregnancy are attenuated in SOCS3 KO mice

Despite the increased sensitivity to leptin (Figure 1E), non-pregnant SOCS3 KO females have a similar food intake (Control: 4.5 ± 0.3 g/day; SOCS3 KO: 4.6 ± 0.3 g/day; p = 0.73) and body weight (Figure 2B) compared with control animals, and only a slight decrease in fat mass (Figure 2C). To investigate whether SOCS3 plays a role in the leptin resistance and metabolic changes observed during pregnancy, females were bred and monitored daily to detect the copulatory plug, indicating the first day of pregnancy (P1). Then, they were single-housed, and their body weight and food intake were recorded daily during the gestation, lactation and postweaning periods. SOCS3 KO females exhibited normal fertility rates (data not shown) and did not

**Figure 1:** Validation of mice lacking SOCS3 in LepR-expressing cells. (A) Gene expression analysis in the hypothalamus of nulliparous (n = 8) and pregnant (n = 7) wild-type mice to determine candidate genes involved in leptin resistance during pregnancy. (B) PCR genotyping from tail biopsies to identify the loxP-flanked Socs3 allele (upper picture) or the LepR-ires-Cre allele (lower picture) in wild-type, control and SOCS3 KO mice. (C) Deletion of SOCS3 in LepR-expressing cells prevented the leptin-induced increase in hypothalamic SOCS3 expression after 1 h (n = 6/group). (D) SOCS3 KO mice did not show the typical increase in hypothalamic SOCS3 expression during pregnancy (n = 7–8). (E) SOCS3 KO mice exhibited longer, sustained leptin-induced phosphorylation of STAT3 (pSTAT3) and did not exhibit changes in SOCS3 protein levels in the hypothalamus compared to control mice (n = 3/group). *p < 0.05.
experience any noticeable pregnancy complications. As expected, control animals showed a progressive increase in food intake during gestation (Figure 2A). Remarkably, SOCS3 KO mice maintained their food intake significantly lower than control animals from P5 to P17 (Figure 2A). During pregnancy, body weight increased progressively in control mice, whereas in SOCS3 KO females this increase was attenuated (Figure 2B). Because adiposity increased during gestation in control animals (Figure 2C), we hypothesized that the lower weight gain of pregnant SOCS3 KO females was due to the prevention of fat mass accumulation. Accordingly, deletion of SOCS3 from LepR-expressing cells reduced the accumulation of fat mass by approximately 80% during pregnancy (Figure 2C). Consequently, pregnant SOCS3 KO females exhibited the same degree of adiposity as nulliparous controls.

Pups had similar body weight at embryo stage (E16) or at birth in control and SOCS3 KO groups (Supplemental Figure 2). To ensure comparable metabolic demands during lactation, we standardized to 6 pups per litter. Lactating control animals exhibited profound increases in food intake (Figure 2A). However, hyperphagia during lactation was markedly reduced by SOCS3 deletion suggesting that ongoing leptin resistance contributes to the hyperphagia of lactation. Food intake returned to baseline levels after weaning in both groups (Figure 2A). In addition, control animals remained significantly heavier than SOCS3 KO females during lactation (Figure 2B). Pups from SOCS3 KO dams showed a lower weight gain rate resulting in a significantly lower body weight from day 14 on compared to control litters (Supplemental Figure 2).

Pregnancy is considered an important risk factor for obesity in women [4]. To investigate whether SOCS3 deletion prevented postpartum weight retention, we compared the body weight of age-matched nulliparous and primiparous mice. In nulliparous mice, we found no differences in body weight between the groups (Figure 2D). However, primiparous control animals showed sustained increases in body weight and adiposity than nulliparous controls (Figure 2D,E). Notably, SOCS3 deletion mitigated pregnancy-induced increases in body weight and fat accumulation (Figure 2D,E). Therefore, long-term postpartum fat retention was prevented by SOCS3 conditional deletion.

3.4. SOCS3 deletion in LepR-expressing cells precludes the development of leptin resistance during pregnancy
It remains unknown whether the development of leptin resistance leads to the metabolic changes observed during pregnancy. Control mice exhibited a marked increase in serum leptin concentration during late pregnancy (Figure 3A). Since hyperleptinemia is a common feature of leptin resistance [12,14,15], these results corroborate previous findings indicating that late pregnant animals are leptin resistant [5—
Notably, no changes in leptin levels were observed in pregnant SOCS3 KO mice suggesting improved leptin sensitivity (Figure 3A). To directly evaluate leptin sensitivity, osmotic pumps delivering leptin were implanted subcutaneously at day 5 of pregnancy in control and SOCS3 KO mice. Blood analysis at day 16 of pregnancy indicated that leptin-treated control and SOCS3 KO mice had similarly high leptin levels (Supplemental Figure 3). Control mice showed reduced weight gain at the beginning of leptin treatment. However, by late gestation, their weight gain was similar to non-treated animals (Figure 3B). These results are in accordance with the fact that leptin resistance arises at midpregnancy towards the end of gestation, coinciding with the period of highest weight gain rate and hyperphagia (Supplemental Figure 4). In contrast, leptin-treated SOCS3 KO mice had a lower rate of weight gain by late pregnancy (Figure 3C). By the end of pregnancy, leptin-treated controls showed similar rate of weight gain as the non-treated controls (Figure 3D and Supplemental Figure 4). Conversely, leptin-treated SOCS3 KO mice gained significantly less weight during pregnancy than non-treated animals (Figure 3D and Supplemental Figure 4). Although leptin treatment was able to reduce food intake of control animals, the anorexigenic effects of leptin were significantly stronger in SOCS3 KO mice, completely preventing hyperphagia during late pregnancy (Figure 3E). Moreover, leptin drastically reduced the adiposity of pregnant SOCS3 KO mice by nearly eliminating their fat deposits (Figure 3F).
To assess region-specific changes in leptin sensitivity, another group of pregnant control and SOCS3 KO mice received an acute leptin injection to determine the activation of the STAT3 signaling pathway in the brain (Figure 3G). No differences between control and SOCS3 KO mice were observed in the number of leptin-induced pSTAT3-ir cells in the medial preoptic area (Figure 3H,L), lateral hypothalamic area, dorsomedial nucleus of the hypothalamus (DMH; Figure 3J,N) and nucleus of the solitary tract. However, SOCS3 KO mice exhibited increased pSTAT3-ir cells in the arcuate nucleus of the hypothalamus (ARH; Figure 3I,M), ventromedial nucleus of the hypothalamus (VMH; Figure 3I,M) and ventral premammillary nucleus (Figure 3K,O). Therefore, mice carrying SOCS3 deletion in LepR-expressing cells exhibited improved leptin sensitivity during pregnancy, which was likely responsible for the prevention of metabolic changes during pregnancy. Similarly to that observed in DIO [18,19], some brain areas are not affected by leptin resistance during gestation (i.e., DMH). However, pregnant SOCS3 KO mice showed improved responsiveness to leptin in hypothalamic nuclei related to energy balance regulation including the ARH and VMH [20]. Interestingly, these same areas are prone to developing leptin resistance induced by high-fat diets [18,19] or during pregnancy [5,6].

3.5. Improved glucose homeostasis and protection against GDM in SOCS3 KO mice

Pregnancy leads to the development of insulin resistance [3], although the mechanisms that cause this condition are unclear. No significant changes in serum insulin or glucagon levels were observed in pregnant control or SOCS3 KO mice (Supplemental Figure 5). However, SOCS3 KO mice showed improved glucose tolerance during pregnancy (Figure 4A). Remarkably, pregnant SOCS3 KO mice required less insulin secretion during the GTT to control their glucose levels (Figure 4B). Additionally, SOCS3 KO mice subjected to an ITT exhibited increased insulin sensitivity during late pregnancy (Figure 4C), which is the period associated with the highest risk of developing GDM [1]. Although these results indicate significant improvements in glucose homeostasis in pregnant SOCS3 KO mice, it remains unclear whether these changes can protect them from GDM. Thus, we studied GDM using a previously described protocol [9]. Mice received a single injection of STZ on P5 to induce lesions in their pancreatic β-cells. Although no changes were observed between the groups in serum insulin levels after the STZ treatment (p = 0.98; data not shown), control animals were hyperglycemic by P13 (>200 mg/dL), whereas SOCS3 KO mice showed no significant changes in glycemia.
(Figure 4D). Accordingly, the results of a GTT performed at day 14 indicated considerably better glucose tolerance in STZ-injected SOCS3 KO mice compared with controls (Figure 4E).

Central leptin signaling modulates insulin sensitivity in peripheral tissues [14,20–22]. The regulation of glucose homeostasis by hypothalamic neurons requires the activity of KATP channels [23,24] and is affected by specific isoforms of protein kinase C (PKC) [25,26]. We observed an upregulation of the SUR2 KATP channel subunit as well as a reduced expression of PKCβ in the hypothalamus of pregnant SOCS3 KO mice (Figure 4F). To investigate whether these changes affected insulin sensitivity in peripheral tissues, pregnant mice received an acute insulin stimulus to assess the activation of the insulin receptor (IR) signaling pathway. Insulin induced the phosphorylation of the IR and AKT in the skeletal muscle (Figure 4G) and liver (Figure 4H).

However, SOCS3 KO mice showed increased IR phosphorylation in the skeletal muscle, suggesting higher insulin responsiveness (Figure 3G). No differences between control and SOCS3 KO groups were observed in the insulin sensitivity (Figure 4H) or the expression of genes involved in glucose and lipid metabolism in the liver (Supplemental Figure 6). These results indicate that alterations in hypothalamic SOCS3 expression are responsible for inducing insulin resistance during pregnancy. These effects involve changes in the hypothalamic expression of KATP channels and PKCβ, leading to better insulin responsiveness in skeletal muscles. Remarkably, SOCS3 deletion in LepR-expressing cells is sufficient to prevent the development of GDM in the STZ-induced model.

4. DISCUSSION

In the present study, we identified a key molecular mechanism responsible for inducing metabolic changes during pregnancy. By preventing SOCS3 expression only in LepR-expressing cells, we turned off most of the pregnancy-induced metabolic changes without affecting the ability of the females to carry their gestation to term. Thus, SOCS3 may represent an integrative protein recruited by multiple signals to induce gestational metabolic changes. In the present obese-sogenic environment, this response may have become maladaptive leading many women to present metabolic imbalances during pregnancy such as EGWG and GDM. These conditions are becoming a common complication for obstetric practice as well as a risk factor of higher morbidity and mortality in pregnancy. These conditions are becoming a common complication for obstetric practice as well as a risk factor of higher morbidity and mortality in pregnancy. These conditions are becoming a common complication for obstetric practice as well as a risk factor of higher morbidity and mortality in pregnancy.

Earlier studies have described the role of SOCS3 in modulating leptin sensitivity in DIO models [12–15]. Haploinsufficiency or neuronal SOCS3 deficiency partially protects mice against DIO and insulin resistance [12–15]. Surprisingly, deletion of SOCS3 from LepR-expressing cells did not prevent DIO, although improved diet-induced insulin resistance [14]. In accordance, overexpression of SOCS3 in LepR-expressing cells did not lead to obesity [35]. These results contrast with the present findings indicating that SOCS3 deficiency in LepR-expressing cells leads to drastic consequences in the regulation of energy balance in both DIO and pregnancy. However, SOCS3 expression in LepR cells modulates the energy balance more significantly during pregnancy.

Based on our findings, therapies that target SOCS3 could become a promising approach to prevent and treat gestational metabolic diseases. Of note, currently there is no specific treatment for pregnancy-induced metabolic imbalances. Nonetheless, SOCS3 is involved in different biological functions, and systemic manipulations of SOCS3...
may cause unpredicted effects. For example, SOCS3 ablation may influence placental functions [36]. Therefore, more studies are still necessary to assess the risk-benefits of manipulating SOCS3 during pregnancy. It seems, however, that central inhibition of SOCS3 may produce more benefits than risks not only for the treatment of gestational metabolic imbalances, but for obesity and diabetes mellitus as well. Because LepR expression is also found in different organs [37], peripheral tissues may have been affected in SOCS3 KO females. However, this fact did not cause any apparent complications during pregnancy. Regarding the phenotype of pregnant SOCS3 KO females, we cannot rule out that part of it was caused by peripheral SOCS3 deletion. For example, liver- or skeletal muscle-specific SOCS3 deletion increases insulin sensitivity in those particular tissues [38,39]. However, this fact is unlikely because liver-specific SOCS3 ablation paradoxically leads to obesity [38] which is incompatible with the phenotype of SOCS3 KO females observed in our study. Additionally, since the recovery of leptin sensitivity during pregnancy may represent a major aspect in the prevention of metabolic changes in pregnant SOCS3 KO females, and it is well-known that the key metabolic effects of leptin are mediated by the brain [40,41], the metabolic phenotype of pregnant SOCS3 KO mice is likely caused by central mechanisms. In conclusion, our study identified the increased hypothalamic expression of SOCS3 as a key mechanism responsible for inducing pregnancy-induced leptin resistance and metabolic adaptations. These findings not only help to explain a common phenomenon of the mammalian physiology, but it may also aid in the development of approaches to prevent and treat gestational metabolic imbalances.
