Computation of Optimal Transport on
Discrete Metric Measure Spaces

Abstract

In this paper we investigate the numerical approximation of an analogue of the Wasserstein distance for optimal transport on graphs that is defined via a discrete modification of the Benamou–Brenier formula. This approach involves the logarithmic mean of measure densities on adjacent nodes of the graph. For this model a variational time discretization of the probability densities on graph nodes and the momenta on graph edges is proposed. A robust descent algorithm for the action functional is derived, which in particular uses a proximal splitting with an edgewise nonlinear projection on the convex subgraph of the logarithmic mean. Thereby, suitable chosen slack variables avoid a global coupling of probability densities on all graph nodes in the projection step. For the time discrete action functional $\Gamma$–convergence to the time continuous action is established. Numerical results for a selection of test cases show qualitative and quantitative properties of the optimal transport on graphs. Finally, we use our algorithm to implement a JKO scheme for the gradient flow of the entropy in the discrete transportation distance, which is known to coincide with the underlying Markov semigroup, and test our results against a classical backward Euler discretization of this discrete heat flow.

Key Words: optimal transport on graphs, proximal splitting, gradient flows

1 Introduction

For a metric space $(X,d)$ and a weighting exponent $p \in [1, \infty)$ optimal transport induces the $p$-Wasserstein distances $W_p$ on the probability measures over $X$. A remarkable property of Wasserstein distances is that they form a length space if the base space $(X,d)$ is a length space, inducing the so-called displacement interpolation between probability measures [McC97]. The celebrated Benamou–Brenier formula for $W_2$ over $\mathbb{R}^n$ [BB00] can be interpreted as an explicit search for the shortest path between two probability measures. In the last two decades the geometry of metric spaces has extensively been studied by means of optimal transport. In explicit it has been observed that the 2-Wasserstein metric over probability densities in $\mathbb{R}^n$ formally resembles a Riemannian manifold [Ott01] and that various diffusion-type equations can be interpreted as gradient flows for entropy-type functionals with respect to this metric [JKO98]. For a comprehensive introduction we refer to the monographs [Vil09, San15].

§Institute for Numerical Simulation, University of Bonn
Unfortunately, this rich geometry is not directly available when the base space $X$ is discrete, since $W_2$ degenerates and does not admit geodesics. Maas [Maa11] introduced a transport-type Riemannian metric $W$ on probability measures over a discrete space $X$ equipped with a reversible Markov kernel $Q$, based on an adaption of the Benamou–Brenier formula. A key ingredient in the construction is the choice of a ‘mass averaging’ function $\theta$ that interpolates the amount of mass on neighbouring graph vertices. For the particular choice of $\theta$ being the logarithmic mean, the heat equation (with respect to the underlying Markov kernel) arises as gradient flow of the entropy with respect to this metric [Maa11, Mie11], yielding a discrete analogue of Otto’s interpretation of diffusive PDEs, see also [EM14] for a generalization to non-linear evolution equations on discrete spaces. In analogy to the Lott–Sturm–Villani theory the displacement interpolation on graphs has been used to introduce a notion of Ricci curvature lower bounds for discrete spaces equipped with Markov kernels [EM12] that implies a variety of functional inequalities in analogy to the theory of Lott–Sturm–Villani. The study of transport-type distances on discrete domains has various connections to the original Wasserstein distances on continuous domains. Approximating a torus with an increasingly finer toroidal graph, the discrete transport metric $W$ has been shown to converge to the continuous underlying 2-Wasserstein distance on the torus in the sense of Gromov–Hausdorff [GM13]. Conversely, the introduction of a mass averaging function for discrete spaces has in turn inspired the design of new non-local transport-type metrics in continuous domains [Erb14].

Computing classical Wasserstein distances $W_2$ numerically is often a challenge. While the classical Kantorovich formulation via transport couplings is a standard linear program, its naive dense form requires $(\text{card}X)^2$ variables which may quickly become computationally unfeasible as $X$ increases in size. On arbitrary metric graphs $(X,d)$ an additional problem arises: only local edge lengths are usually prescribed and the full distance function $d : X \times X \to \mathbb{R}$ is in general unknown a priori. On large graphs, computing $d$ from local edge lengths may be computationally prohibitive or even storing $d$ may exceed the memory capacities. Owing to its particular structure, the 1-Wasserstein distance over a discrete graph can be reformulated as a min cost flow problem along its edges, thus drastically reducing the number of required variables if the graph is sparse and requiring no pre-computation of $d$, see for instance [AMO93]. On continuous domains this corresponds to Beckmann’s problem [San15]. A numerical scheme tailored to application on meshed surfaces is presented in [SRGB14]. A computational approach that uses quadratic regularization to break the non-uniqueness of the optimal flow is described in [ES17].

For the 2-Wasserstein distance on continuous domains the Benamou–Brenier formula serves a similar purpose, see for instance [PPO14] for a numerical scheme based on proximal point algorithms. However, this does not immediately carry over to discrete graphs, as the mass averaging function $\theta$ introduces a non-trivial coupling of the mass variables along graph edges. In [SRGB16] a Benamou–Brenier-type transport distance on discrete metric graphs is developed, similar to the construction of Maas, and a corresponding numerical scheme is developed. A crucial design choice is that $\theta$ is picked to be the harmonic mean which allows the application of second-order convex cone programs for numerical optimization. This does not extend to other choices of $\theta$ and thus, for instance, hinders the numerical study of the gradient flow when $\theta$ is the logarithmic mean.

**Contribution**

In this article we present a scheme for the numerical approximation of the distance $W$ on discrete sets $X$ equipped with irreducible Markov kernels $Q$ as introduced by Maas. We pick up the Benamou–Brenier-type formulation and provide a temporal discretization of the action func-
tional to obtain a finite-dimensional convex problem and prove $\Gamma$-convergence of the discretized functional to the original problem, as well as strong convergence of the discrete geodesics to the continuous geodesics. To overcome the strong coupling of mass variables along graph edges caused by the mass averaging function we introduce a set of slack variables to remedy this entanglement. This allows us to apply a robust proximal point algorithm for the optimization. Due to the slack variables, all involved proximal mappings can be computed efficiently by either solving a sparse linear program (if $Q$ is sparse) or by decomposing them into independent low-dimensional sub-problems.

In particular this numerical scheme does not depend critically on the choice of $\theta$ and can be quickly adapted to different variants. We provide formulas for the logarithmic and geometric mean. For a series of numerical test cases we visualize and discuss the behaviour of the interpolating flow. Finally, we adopt the algorithm to approximate gradient flows with respect to the discrete transportation distance $W$. In particular, we test the algorithm against a classical backward Euler discretization of the heat equation on a graph which coincides with the gradient flow of the entropy.

Organization

The paper is organized as follows. At first we review the construction of the $L^2$-Wasserstein metric on discrete spaces by Maas [Maa11] in Section 2. Then, in Section 3 we will derive the time discretization and establish $\Gamma$-convergence of the time discrete action functional and the convergence of time discrete geodesics to a continuous geodesic. Next, the proximal splitting algorithm with suitably chosen slack variables is presented in detail in Section 4. Numerical results are discussed in Section 5 and the experimental comparison of solutions of a JKO scheme for the entropy and solutions of the Markov semigroup are presented in Section 6.

2 Optimal transport on graphs

In this section we briefly review the discrete transportation metric on the space of probability measures over a graph and in particular recall the basic definitions and discuss the analogy to the $L^2$-Wasserstein metric on probability measures over $\mathbb{R}^n$. Then we derive a priori bounds on feasible curves of measures.

2.1 The discrete transportation distance

Let $\mathcal{X}$ be a finite set and let $Q : \mathcal{X} \times \mathcal{X} \rightarrow [0, \infty)$ be the transition rate matrix of a continuous time Markov chain on $\mathcal{X}$. I.e. we have $Q(x, y) \geq 0$ for $x \neq y$ and make the convention that $Q(x, x) = 0$ for all $x \in \mathcal{X}$. Then $\mathcal{X}$ can be interpreted as the set of vertices of a graph with directed edges $(x, y)$ for those $(x, y) \in \mathcal{X} \times \mathcal{X}$ with positive weight $Q(x, y)$. We assume the Markov chain to be irreducible or equivalently the corresponding graph to be strongly connected. Thus, there exists a unique stationary distribution $\pi : \mathcal{X} \rightarrow (0, 1]$ of the Markov chain with $\sum_{x \in \mathcal{X}} \pi(x) = 1$. We further assume that the Markov chain is reversible with respect to $\pi$, i.e. the detailed balance condition $\pi(x)Q(x, y) = \pi(y)Q(y, x)$ holds for all $x, y \in \mathcal{X}$. Now, the set of probability densities on $\mathcal{X}$ with respect to $\pi$ is given by

$$\mathcal{P}(\mathcal{X}) := \left\{ \rho : \mathcal{X} \rightarrow \mathbb{R}^+_0 : \sum_{x \in \mathcal{X}} \pi(x)\rho(x) = 1 \right\}.$$
For brevity, in the following we will write $\mathbb{R}^X$ and $\mathbb{R}^{X \times X}$ for the spaces of real functions over $X$ and $X \times X$ respectively.

Next, we define the following inner products on $\mathbb{R}^X$ and $\mathbb{R}^{X \times X}$

$$\langle \phi, \psi \rangle_\pi := \sum_{x \in X} \phi(x) \psi(x) \pi(x), \quad \langle \Phi, \Psi \rangle_Q := \frac{1}{2} \sum_{x,y \in X} \Phi(x,y) \Psi(x,y) Q(x,y) \pi(x) \pi(y)$$

(1)

for $\phi, \psi \in \mathbb{R}^X$ and $\Phi, \Psi \in \mathbb{R}^{X \times X}$. The corresponding induced norms are denoted by $| \cdot |_\pi$ and $| \cdot |_Q$. A discrete gradient $\nabla X : \mathbb{R}^X \to \mathbb{R}^{X \times X}$ and a discrete divergence $\text{div}_X : \mathbb{R}^{X \times X} \to \mathbb{R}^X$ are given by

$$\nabla X \psi(x,y) := \psi(x) - \psi(y), \quad \text{div}_X \Psi(x) := \frac{1}{2} \sum_{y \in X} \Psi(y,x) \psi(y,x) - \Psi(x,y).$$

(2)

Then the duality between these two operators formulated as the discrete integration by parts formula

$$\langle \phi, \text{div}_X \Psi \rangle_\pi = -\langle \nabla X \phi, \Psi \rangle_Q$$

can easily be verified. The associated discrete Laplace-operator $\Delta_X : \mathbb{R}^X \to \mathbb{R}^X$ is given by

$$\Delta_X \psi(x) := \text{div}_X(\nabla X \psi(x)) = \sum_{y \in X} Q(x,y) [\psi(y) - \psi(x)] = (Q - D) \psi(x),$$

where $D = \text{diag}(\sum_y Q(x,y))_{x \in X}$. The graph divergence allows to formulate a continuity equation for time-dependent probability densities $\rho : [0,1] \to \mathbb{R}^X$ and momenta $m : [0,1] \to \mathbb{R}^{X \times X}$ describing the flow of mass along the graph edges. In explicit, we consider the following definition of solutions to the continuity equation with boundary values at time $t = 0$ and $t = 1$.

**Definition 2.1 (Continuity equation).** The set $CE(\rho_A, \rho_B)$ of solutions of the continuity equations for given boundary data $\rho_A, \rho_B \in \mathcal{P}(X)$ is defined as the set of all pairs $(\rho, m)$ with $\rho : [0,1] \times \mathbb{R}^X \to \mathbb{R}$ and $m : [0,1] \times \mathbb{R}^{X \times X} \to \mathbb{R}$ measurable, such that

$$\int_0^1 \langle \partial_t \rho(t, \cdot), \rho(t, \cdot) \rangle_\pi + \langle \nabla X \rho(t, \cdot), m(t, \cdot) \rangle_Q \, dt = \langle \rho(1, \cdot), \rho_B \rangle_\pi - \langle \rho(0, \cdot), \rho_A \rangle_\pi$$

(3)

for all $\varphi \in C^1([0,1], \mathbb{R}^X)$.

For $m \in L^2((0,1), \mathbb{R}^{X \times X})$ (see Lemma 2.5) one gets $\rho \in H^{1,2}((0,1), \mathbb{R}^X)$ and thus $\partial_t \rho + \text{div}_X m = 0$ holds a.e. Furthermore, $\rho \in C^0([0,1], \mathbb{R}^{X \times X})$ and $\rho(1, \cdot) = \rho_B$, $\rho(0, \cdot) = \rho_A$. If $\rho(t, \cdot) \geq 0$ is ensured for all $t \in (0,1)$ via a finite energy property (see (5) below), then testing with $\varphi(t, x) = \zeta(t)$ implies that $\rho(t, \cdot) \in \mathcal{P}(X)$.

The Benamou–Brenier formula [BB00] asserts that the squared $L^2$-Wasserstein distance for probability measures in $\mathbb{R}^n$ is the minimum of an action functional over solutions to the corresponding continuity equation. Formally the action functional can be interpreted as a Riemannian path length [Ott01]. To construct an analogous action functional for solutions $(\rho, m) \in CE(\rho_A, \rho_B)$ a mass density on edges has to be deduced from the the mass densities on the edge nodes. To this end, one defines an averaging function $\theta : (\mathbb{R}^+_0)^2 \to \mathbb{R}^+_0$ which satisfies:

$\theta$ is continuous, concave, 1-homogeneous, and symmetric, $\theta$ is $C^\infty$ on $(0, +\infty)^2$, $\theta(0,s) = \theta(s,0) = 0$ and $\theta(s, s) = s$ for $s \in \mathbb{R}^+_0$, $\theta(s,t) > 0$ if $s > 0$ and $t > 0$, and $s \mapsto \theta(t,s)$ is monotone increasing on $\mathbb{R}^+_0$ for fixed $t \in \mathbb{R}^+_0$.
It will be useful to consider $\theta$ as a concave function $\mathbb{R}^2 \to \mathbb{R} \cup \{-\infty\}$. Therefore, we will set $\theta(s, t) = -\infty$ when $\min\{s, t\} < 0$. Possible choices for $\theta$ are for example the logarithmic mean $\theta_{\log}$ or the geometric mean $\theta_{\text{geo}}$ for $s, t \in \mathbb{R}_0^+$:

$$\theta_{\log}(s, t) = \begin{cases} 0, & \text{if } s = 0 \text{ or } t = 0 \\ s, & \text{if } s = t \\ \frac{t-s}{\log(t) - \log(s)}, & \text{otherwise} \end{cases}, \quad \theta_{\text{geo}}(s, t) = \sqrt{st}. \quad (4)$$

Note that the arithmetic mean is not admissible. Based on this averaging function one can define the discrete transportation distance on $\mathcal{P}(\mathcal{X})$.

**Definition 2.2** (Action functional and distance). The action functional for measurable functions $\rho : [0, 1] \to \mathbb{R}^X$ and $m : [0, 1] \to \mathbb{R}^{X \times X}$ is defined as

$$\mathcal{A}(\rho, m) = \frac{1}{2} \int_0^1 \sum_{s, t \in \mathcal{X}} \alpha(\rho(t, x), \rho(t, y), m(t, x, y)) \cdot Q(x, y) \cdot \pi(x) \, dt$$

with $\alpha : \mathbb{R}^3 \to \mathbb{R} \cup \{\infty\}$; $(s, t, m) \mapsto \begin{cases} \frac{m^2}{m(s, t)} & \text{if } \theta(s, t) > 0, \\ 0 & \text{if } \theta(s, t) = 0 \text{ and } m = 0, \\ +\infty & \text{else.} \end{cases} \quad (5)$

The energy is then given by

$$\mathcal{E}(\rho, m) = \mathcal{A}(\rho, m) + I_{CE(\rho_A, \rho_B)}(\rho, m),$$

where $I_{CE(\rho_A, \rho_B)}$ is the indicator functional, which is zero for $(\rho, m)$ in $CE(\rho_A, \rho_B)$ and $\infty$ otherwise. The induced discrete transportation distance is obtained by

$$\mathcal{W}(\rho_A, \rho_B) = \sqrt{\inf \mathcal{E}(\rho, m)}. \quad (6)$$

Note that $\alpha$ is convex and lower semi-continuous and $CE(\rho_A, \rho_B)$ is a convex set. Hence, $(6)$ is a convex optimization problem. In is shown in [Maa11, Theorem 3.8] that the mapping $\mathcal{W} : \mathcal{P}(\mathcal{X}) \times \mathcal{P}(\mathcal{X}) \to \mathbb{R}$ defines a metric on $\mathcal{P}(\mathcal{X})$, provided

$$\int_0^1 \frac{1}{\sqrt{\theta(1-r, 1+r)}} \, dr < \infty.$$

This is the case for the logarithmic mean $\theta_{\log}$ and the geometric mean $\theta_{\text{geo}}$. In [EM12, Theorem 3.2] it is shown that the infimum in $(6)$ is attained by an optimal pair $(\rho, \psi)$. The curve $(\rho_t)_{t \in [0, 1]}$ is a constant speed geodesic for the distance $\mathcal{W}$, i.e. it holds $\mathcal{W}(\rho_t, \rho_s) = |t-s| \mathcal{W}(\rho_A, \rho_B)$ for all $s, t \in [0, 1]$.

### 2.2 A priori bounds

In what follows we will investigate the numerical approximation of $\mathcal{W}$ using a suitable Galerkin discretization in time and solving the resulting discrete convex optimization problem. Here the nonlinear averaging function $\theta$ and the resulting coupling of the values of the probability density on neighbouring nodes will require special treatment in order to obtain a robust and effective solution scheme. To this end, we first discuss a few simplifications of the optimization problem $(6)$ that will help to reduce the computational complexity.
Remark 2.3 (Sparsity of kernel Q). Let $S = \{(x, y) \in X^2 : Q(x, y) > 0\}$ be the set of 'edges' indicated by non-zero transition probability. As $Q$ is reversible, one finds $(x, y) \in S$ iff $(y, x) \in S$. Furthermore, $\text{div}_X m(t, \cdot)$ and $A(m, p)$ for $m : [0, 1] \rightarrow \mathbb{R}^{X \times X}$ only depend on values of $m(t, x, y)$ where $(x, y) \in S$. Hence, if the kernel $Q$ is sparse, i.e. if $S$ is only a small subset of $X \times X$ this implies a considerable reduction of computational complexity.

In addition, the following Lemma allows to replace the two variables $m(t, x, y)$ and $m(t, y, x)$ by one effective variable, further reducing the problem size.

**Lemma 2.4** (Antisymmetry of optimal momentum). If $W(\rho_A, \rho_B)$ is finite and if $\rho : [0, 1] \rightarrow \mathbb{R}^X$ and $m : [0, 1] \rightarrow \mathbb{R}^{X \times X}$ are optimal for (6) then $m(t, x, y) = -m(t, y, x)$ $t$-almost everywhere, whenever $(x, y) \in S$ (see above remark for definition of $S$).

**Proof.** Let $\rho : [0, 1] \rightarrow \mathbb{R}^X$ and $m : [0, 1] \rightarrow \mathbb{R}^{X \times X}$ be given such that $E(\rho, m) < \infty$. Now set

$$\tilde{m}(t, x, y) := -m(t, y, x).$$

One quickly verifies that $\text{div}_X \tilde{m} = \text{div}_X m$ and that thus $(\rho, \tilde{m}) \in C(E(\rho_A, \rho_B))$ as well. Besides, by using that $Q(x, y) \pi(x) = Q(y, x) \pi(y)$ and $\alpha(s, t, m) = \alpha(t, s, -m)$ one finds that $A(\rho, \tilde{m}) = A(\rho, m)$. Let now $\overline{m} = \frac{1}{2}(m + \tilde{m})$. Note that $\overline{m}(t, x, y)$ is anti-symmetric in $x$ and $y$. By convexity of $C(E(\rho_A, \rho_B))$ one gets $(\rho, \overline{m}) \in C(E(\rho_A, \rho_B))$ and by convexity of $A$ one finds

$$A(\rho, \overline{m}) \leq \frac{1}{2} (A(\rho, m) + A(\rho, \tilde{m})) = A(\rho, m).$$

Further, the finiteness of $A(\rho, m)$ implies that $m(t, x, y) = 0$ when $\theta(\rho(t, x), \rho(t, y)) = 0$ and $(x, y) \in S$ $t$-almost everywhere, values of $m(t, x, y)$ for $(x, y) \notin S$ will have no impact on $A$, and the function $x \mapsto \alpha(s, t, x)$ is even strictly convex for fixed $s, t > 0$. Hence, we observe that $A(\rho, \overline{m}) < A(\rho, m)$ unless $\overline{m}$ already coincides with $m$ for almost every $t$ and all $(x, y) \in S$. 

In the $\Gamma$-convergence analysis we will make use on the following $L^2$ bound for the momentum. Let us introduce the constants

$$C^* := \max_{x \in X} \sum_y Q(x, y),$$

$$C_* := \min_{x, y \in X, Q(x, y) > 0} Q(x, y)\pi(x).$$

**Lemma 2.5** ($L^2$ bound for the momentum). Let $(\rho, m) : [0, 1] \rightarrow \mathbb{R}^X \times \mathbb{R}^{X \times X}$ be a measurable path with energy $E(\rho, m) \leq E < \infty$. Then, $m$ and $\rho$ are uniformly bounded in $L^2((0, 1), \mathbb{R}^{X \times X})$ and $H^{1, 2}((0, 1), \mathbb{R}^X) \cap C^{0, 1}([0, 1], \mathbb{R}^X)$, respectively, with bounds solely depending on $X$ and $E$.

**Proof.** Since $E(\rho, m) < \infty$, we have $(\rho, m) \in C(E(\rho_A, \rho_B))$, and thus for a.e. $t \in (0, 1)$ the mass is preserved, i.e. $\sum_{x \in X} \rho(t, x)\pi(x) = \sum_{x \in X} \rho_A(x)\pi(x) = 1$. In addition, $\rho(t, x)$ is non-negative for all $x \in X$ and a.e. $t \in (0, 1)$. By symmetry and concavity of $\theta$ and since $\theta(s, s) = s$, we can estimate

$$\theta(\rho(t, x), \rho(t, y)) \leq \theta \left( \frac{\rho(t, x) + \rho(t, y)}{2}, \frac{\rho(t, x) + \rho(t, y)}{2} \right) = \frac{\rho(t, x) + \rho(t, y)}{2}$$
and get
\[
\sum_{x,y \in X} \theta(\rho(t,x), \rho(t,y))Q(x,y)\pi(x) \leq \frac{1}{2} \sum_{x,y \in X} (\rho(t,x)Q(x,y)\pi(x) + \rho(t,y)Q(y,x)\pi(y)) = \frac{1}{2} \sum_{x \in X} \rho(t,x)\pi(x) = C^*.
\]
(8)

Thus, using the Cauchy–Schwarz inequality we obtain
\[
\left( \sum_{x,y \in X} |m(t,x,y)|Q(x,y)\pi(x) \right)^2 \leq \left( \sum_{x,y \in X} \alpha(\rho(t,x), \rho(t,y), m(t,x,y))Q(x,y)\pi(x) \right) \cdot \left( \sum_{x \in X} \theta(\rho(t,x), \rho(t,y)\pi(x)) \right).
\]
Integrating in time we obtain
\[
\int_0^1 \|m(t, \cdot, \cdot)\|^2_Q \, dt = \int_0^1 \sum_{x \in X} m(t, x, y)^2 Q(x, y)\pi(x) \, dt \leq \frac{C^*}{C_*} E.
\]

Finally, using the continuity equation (3) and \( m \) in \( L^2((0,1), \mathbb{R}^X) \) we obtain that
\[
\int_0^1 \|\partial_t \rho\|^2 \, dt \leq \int_0^1 \sum_{x,y} \rho(t,x,y)Q(x,y)^2 \pi(x)dt \leq C^* \int_0^1 \sum_{x,y} m(t,x,y)^2 Q(x,y)\pi(x)dt.
\]
This implies that \( \rho \in H^{1,2}((0,1), \mathbb{R}^X) \) and via the Sobolev embedding theorem we obtain that also \( \rho \in C^\infty((0,1), \mathbb{R}^X) \).

\[\square\]

3 Discretization

3.1 Galerkin discretization

To approximate the minimizers of (6) numerically we choose a Galerkin discretization in time. The time interval \([0,1]\) is divided into \(N\) subintervals \(I_i = [t_i, t_{i+1})\) for \(i = 0, \ldots, N-1\) with uniform step size \(h = \frac{1}{N}\) and \(t_i = ih\). Then, we define discrete spaces
\[
V_{1,n,h} = \{ \psi_h \in C^0([0,1], \mathbb{R}^X) : \psi_h(\cdot)|_{I_i} \text{ is affine} \forall i, 0, \ldots, N-1 \},
\]
\[
V_{0,n,h} = \{ \psi_h : [0,1] \to \mathbb{R}^X : \psi_h(\cdot)|_{I_i} \text{ is constant} \forall i, 0, \ldots, N-1 \},
\]
\[
V_{0,c,h} = \{ \psi_h : [0,1] \to \mathbb{R}^{X \times X} : \psi_h(\cdot)|_{I_i} \text{ is constant} \forall i, 0, \ldots, N-1 \}.
\]

For a function \(\psi_h \in V_{0,n,h}\) or \(V_{0,c,h}\) we will often write \(\psi_h(t_i)\) to refer to its value on the interval \(I_i = [t_i, t_{i+1})\). For a function \(\psi_h \in V_{1,n,h}\) the time-derivative can be interpreted as map
\[
\partial_t : V_{1,n,h} \to V_{0,n,h}, \quad (\partial_t \psi_h)(t_i) = \frac{1}{h}(\psi_h(t_{i+1}) - \psi_h(t_i)) \text{ for } i = 0, \ldots, N-1.
\]

We pick \(V_{1,n,h} \times V_{0,c,h}\) as the space for discretized masses and momenta \((\rho_h, m_h)\). That is, discrete masses \(\rho_h\) are continuous and piecewise affine and the corresponding momenta \(m_h\) will be piecewise constant. \(\partial_t \rho_h\) and \(\text{div}_x m_h\) then lie in \(V_{0,n,h}\). In analogy to Definition 2.1 we define discrete solutions of the continuity equation.
Definition 3.1. The set of solutions to the discretized continuity equation for given boundary values \( \rho_A, \rho_B \in \mathbb{R}^X \) is given by

\[
\mathcal{CE}_h(\rho_A, \rho_B) = \left\{ (\rho_h, m_h) \in V_{n,h}^1 \times V_{e,h}^0 : h \sum_{i=0}^{N-1} \langle \partial_t \rho_h(t_i, \cdot) + \text{div}_X m_h(t_i, \cdot), \varphi_h(t_i, \cdot) \rangle_{\pi} = 0 \ \forall \varphi_h \in V_{n,h}^0, \rho_h(t_0, x) = \rho_A(x), \rho_h(t_N, x) = \rho_B(x) \right\}.
\]

(10)

One can quickly verify that \( \mathcal{CE}_h(\rho_A, \rho_B) = \mathcal{CE}(\rho_A, \rho_B) \cap (V_{n,h}^1 \times V_{e,h}^0) \) and that \( \partial_t \rho_h + \text{div}_X m_h = 0 \) holds for a.e. \( t \) when \( (\rho_h, m_h) \in \mathcal{CE}_h(\rho_A, \rho_B) \). Next, we define a fully discrete action functional in analogy to Definition 2.2 and subsequently a discrete version of the transport metric \( \mathcal{W} \).

Definition 3.2 (Time-discrete action and transportation distance). The averaging operator \( \text{avg}_h \) takes a measure \( \psi \in \mathcal{M}([0,1], \mathbb{R}^X) \) to its average values on time intervals \( I_i \):

\[
\text{avg}_h : \mathcal{M}([0,1], \mathbb{R}^X) \rightarrow V_{n,h}^0, \quad (\text{avg}_h \psi)(t_i) = \psi(l_i) \text{ for } i = 0, \ldots, N - 1.
\]

Analogously we declare the \( \text{avg}_h \) operator for \( \mathbb{R}^X \times X \)-valued measures. Note that for \( \psi_h \in V_{n,h}^1 \) one finds \( (\text{avg}_h \psi_h)(t_i) = \frac{1}{2}(\psi_h(t_i) + \psi_h(t_{i+1})) \). For \( (\rho, m) \in \mathcal{M}([0,1], \mathbb{R}^X) \times \mathcal{M}([0,1], \mathbb{R}^X) \times \mathbb{R}^{X \times X} \) the discrete approximation for the action is given by

\[
\mathcal{A}_h(\rho, m) = \mathcal{A}(\text{avg}_h \rho, \text{avg}_h m)
\]

\[
= \frac{h}{2} \sum_{i=0}^{N-1} \sum_{x,y \in X} \alpha (\text{avg}_h \rho(t_i, x), \text{avg}_h \rho(t_i, y), \text{avg}_h m(t_i, x, y)) \bar{Q}(x, y) \pi(x).
\]

Finally, the time discrete energy functional is defined by \( \mathcal{E}_h(\rho, m) = \mathcal{A}_h(\rho, m) + \int \mathcal{CE}_h(\rho, \rho_B) (\rho, m) \) and for the associated time discrete approximation of the transportation distance one obtains

\[
\mathcal{W}_h(\rho_A, \rho_B) = \sqrt{\inf \mathcal{E}_h(\rho, m)}.
\]

(11)

Note that the indicator function of the discrete continuity equation entails the constraint \( (\rho, m) \in V_{n,h}^1 \times V_{e,h}^0 \). These spaces can be represented by finite-dimensional vectors, the operators \( \partial_t \) and \( \text{avg}_h \) can be represented as finite-dimensional matrices and the continuity equation becomes a finite-dimensional affine constraint. Thus, (11) is indeed a finite-dimensional convex optimization problem. Its numerical solution by using proximal mappings will be detailed in Section 4.

3.2 \( \Gamma \)-convergence

In the following, we will prove a \( \Gamma \)-convergence result of the discrete energy functional, which will justify our discretization. First, we construct explicitly continuous and discrete trajectories between an arbitrary probability distribution on \( X \) and the uniform probability density \( 1 \in \mathcal{P}(X) \) given by \( 1(x) = 1 \). We show that these trajectories have uniformly bounded energy, which will be essential in the \( \Gamma \)-lim sup inequality in Theorem 3.6. Let us define the Lagrange interpolation operator \( I_h : C^0([0,1], \mathbb{R}^X) \rightarrow V_{n,h}^1 \rho \mapsto I_h(\rho) \) given by

\[
(I_h \rho)(t_i, x) := \rho(t_i, x) \quad \forall i = 0, \ldots, N.
\]
Proposition 3.3. There is some constant $C(X) < \infty$ such that for any $\rho_A \in \mathcal{P}(X)$ there is a trajectory $(\rho, m) \in \mathcal{CE}(\rho_A, \mathbb{I})$ with $\mathcal{A}(\rho, m) \leq C(X)$ and $(I_h \rho, \text{avg}_h m) \in \mathcal{CE}_h(\rho_A, \mathbb{I})$ with $\mathcal{A}_h(I_h \rho, \text{avg}_h m) \leq C(X)$ for every $h = 1/N$.

Proof. For $x \in X$ let $\rho_A^x = \frac{1}{\pi(x)} \delta_x$, where $\delta_x$ is the usual Kronecker symbol with $\delta_x(y) = 1$ if $x = y$ and 0 else.

Construction of elementary flows: For $(x, y) \in X \times X$, $x \neq y$, with $Q(x, y) > 0$ we define $L[x, y] \in \mathbb{R}^{X \times X}$ as follows:

$$L[x, y](a, b) = \begin{cases} \frac{1}{Q(x, y)} & \text{if } (a, b) = (x, y), \\ \frac{-1}{\pi(x)} & \text{if } (a, b) = (y, x), \\ 0 & \text{else.} \end{cases}$$

Then $\text{div}_X L[x, y] = \rho_A^y - \rho_A^x$. Now, for any $(x, y) \in X \times X$, $x \neq y$, there exists a path $(x = x_0, x_1, \ldots, x_k = y)$ with $K < \text{card}X$ with $Q(x_k, x_{k+1}) > 0$ for $k = 0, \ldots, K - 1$. We can add the corresponding $L(x_k, x_{k+1})$ along these edges to construct a flow $M[x, y]$ with $\text{div}_X M[x, y] = \rho_A^y - \rho_A^x$. All entries of all $M[x, y]$ are bounded (in absolute value) by $\tilde{C}(X) := \text{card}X/C_\sigma$, where $C_\sigma$ is defined in (7). For $x = y$, $M[x, x]$ is simply zero.

Now assume $\rho_A = \rho_A^x$ for some $x \in X$. Let $m_0 = \sum_{y \in X} M[x, y] \pi(y)$. One finds

$$\text{div}_X m_0 = \sum_{y \in X} \left( \frac{1}{\pi(y)} \delta_y - \frac{1}{\pi(x)} \delta_x \right) \pi(y) = \mathbb{I} - \rho_A^x.$$ 

Again, every entry of $m_0$ is bounded in absolute value by $\tilde{C}(X)$. Now let $m(t) = 2 m_0 t$, $\rho(t) = \rho_A^x + (\text{div}_X m_0)^2 = (1 - t^2) \cdot \rho_A^x + t^2 \cdot \mathbb{I}$. We find $(\rho, m) \in \mathcal{CE}(\rho_A^x, \mathbb{I})$. One has $|m(t, x, y)| \leq t \cdot 2 \tilde{C}(X)$ and $\rho(t, x) \geq t^2$ and using the monotonicity of $a$ for the action $\mathcal{A}$ we get

$$\mathcal{A}(\rho, m) \leq \frac{1}{2} \int_0^1 \sum_{x, y \in X} \frac{(t - 2 \tilde{C}(X))^2}{t^2} Q(x, y) \pi(x) \, dt = 2 \tilde{C}(X)^2 C^*.$$ 

Construction of discrete counterparts: For fixed $h = 1/N$ let $\rho_h = I_h \rho$ and $m_h = \text{avg}_h m$. By construction $(\rho_h, m_h) \in \mathcal{CE}_h(\rho_A^x, \mathbb{I})$. Then, one finds $m_h(t_h, x, y) \leq (i + \frac{1}{2}) h 2 \tilde{C}(X)$, $\rho_h(t_h, x) \geq (i^2 + i + \frac{1}{2}) h^2$, $\text{avg}_h \rho_h(t_h, x) \geq (i^2 + i + \frac{1}{2}) h^2$, and thus

$$\mathcal{A}_h(\rho_h, m_h) = \mathcal{A}(\text{avg}_h \rho_h, m_h) \leq \frac{1}{2} \sum_{i=0}^{N-1} \sum_{x, y \in X} \frac{h^2 4 \tilde{C}(X)^2 (i + \frac{1}{2})^2}{h^2 (i^2 + i + \frac{1}{2})} Q(x, y) \pi(x) \leq 2 \tilde{C}(X)^2 C^*.$$ 

Extension for arbitrary initial data: For given $x \in X$ let $(\rho^x, m^x)$ be the (continuous) trajectory between $\rho_A^x$ and $\mathbb{I}$ as constructed above. Any $\rho_A$ is a superposition of various $\rho_A^x$. 

$$\rho_A = \sum_{x \in X} \rho_A(x) \delta_x = \sum_{x \in X} \rho_A(x) \pi(x) \rho_A^x.$$ 

By linearity of the continuity equation the trajectory $(\rho, m) = \sum_{x \in X} \rho_A(x) \pi(x) \cdot (\rho^x, m^x)$ then lies in $\mathcal{CE}(\rho_A, \mathbb{I})$. Since $\mathcal{A}$ is convex and 1-homogeneous, it is sub-additive. Therefore,

$$\mathcal{A}(\rho, m) \leq \sum_{x \in X} \rho_A(x) \pi(x) \mathcal{A}(\rho^x, m^x) \leq \sum_{x \in X} \rho_A(x) \pi(x) 2 \tilde{C}(X)^2 C^* = 2 \tilde{C}(X)^2 C^*.$$ 

9
For the discrete trajectory the reasoning is completely analogous. Thus the claim follows with 
\[ C(X) = 2 \tilde{C}(X)^2 C^*. \]

**Corollary 3.4.** The above strategy can be used to construct trajectories between arbitrary \( \rho_A, \rho_B \) via \( \mathbb{I} \) as intermediate state. This establishes that \( \mathcal{W} \) and \( \mathcal{W}_b \) are uniformly bounded on \( \mathcal{P}(X)^2 \).

**Remark 3.5.** In [Maa11] it is shown that \( \mathcal{W} \) is bounded if the constant \( C_0 := \int_0^1 \frac{1}{\sqrt{1 - s + t}} \, ds \) is finite. Here, we assumed that \( \theta(s,s) = s \) for \( s \in \mathbb{R}^+_0 \) and that \( s \mapsto \theta(s,t) \) is increasing on \( \mathbb{R}^+_0 \) for fixed \( t \in \mathbb{R}^+_0 \) which implies that \( \theta(s,t) \geq \min\{s,t\} \) for \( s, t \in \mathbb{R}^+ \). This is sufficient for \( C_0 < \infty \).

**Theorem 3.6 (\( \Gamma \)-convergence of time discrete energies).** Let \( \rho_A, \rho_B \) be fixed temporal boundary conditions. Then, the sequence of functionals \( (\mathcal{E}_h)_h \) \( \Gamma \)-converges for \( h \to 0 \) to the functional \( \mathcal{E} \) with respect to the weak* topology in \( \mathcal{M}([0,1], \mathbb{R}^X \times \mathbb{R}^X \times \mathbb{X}) \).

**Proof.** To establish \( \Gamma \)-convergence, we have to verify the \( \Gamma \)-lim inf and \( \Gamma \)-lim sup properties.

For the \( \Gamma \)-lim inf property, we have to demonstrate that the inequality
\[
\mathcal{A}(\rho, m) + I_{CE(\rho, m)}(\rho, m) \leq \liminf_{h \to 0} \mathcal{A}_h(\rho_h, m_h) + I_{CE_h(\rho, m)}(\rho_h, m_h) \tag{12}
\]
holds for all sequences \( (\rho_h, m_h) \overset{\ast}{\rightharpoonup} (\rho, m) \) in \( \mathcal{M}([0,1], \mathbb{R}^X \times \mathbb{R}^X \times \mathbb{X}) \). As \( CE(\rho_A, \rho_B) \) is weak*-closed and \( CE_h(\rho_A, \rho_B) \subset CE(\rho_A, \rho_B) \) the statement is trivial if there is no subsequence with \( (\rho_h, m_h) \in CE(\rho_A, \rho_B) \). Thus, we may assume that all \( (\rho_h, m_h) \) fulfill the discrete continuity equation, that \( (\rho, m) \) fulfills the continuous continuity equation, and all \( \rho_h \) are non-negative.

Now, \( \rho_h \overset{\ast}{\rightharpoonup} \rho \) implies \( \text{avg}_{\mathcal{B}} \rho_h \overset{\ast}{\rightharpoonup} \rho \) and \( \mathcal{A}_h(\rho_h, m_h) = \mathcal{A}(\text{avg}_{\mathcal{B}} \rho_h, m_h) \). Since \( \alpha \) is jointly convex and lower semi-continuous in \( \rho \) and \( m \), the action functional \( \mathcal{A} \) is weak*-lower semi-continuous and (12) holds.

To verify the \( \Gamma \)-lim sup property we need to show that for any \( (\rho, m) \in \mathcal{M}([0,1], \mathbb{R}^X \times \mathbb{R}^X \times \mathbb{X}) \) there exists a recovery sequence \( (\rho_h, m_h) \overset{\ast}{\rightharpoonup} (\rho, m) \) with
\[
\limsup_{h \to 0} \mathcal{A}_h(\rho_h, m_h) + I_{CE_h(\rho, m)}(\rho_h, m_h) \leq \mathcal{A}(\rho, m) + I_{CE(\rho, m)}(\rho, m) \tag{13}
\]
We may assume \( \mathcal{A}(\rho, m) < \infty \) and \( (\rho, m) \in CE(\rho_A, \rho_B) \). Using Lemma 2.5 this implies in particular that \( \rho \in C^{0,\frac{1}{2}}([0,1], \mathbb{R}^X) \). For such a trajectory \( (\rho, m) \) we will construct a recovery sequence in two steps: First, the continuous trajectory \( (\rho, m) \) is regularized, then, the regularized still time continuous trajectory is discretized using local averaging in time. The regularization is necessary to control the effect of the discontinuity of \( a \) at the origin, see (5).

Let \( (\rho_{A,B}, m_{A,B}) \in CE(\rho_A, \mathbb{I}) \) be the trajectory from \( \rho_A \) to \( \mathbb{I} \) as constructed in Proposition 3.3, analogously let \( (\rho_{B,B}, m_{B,B}) \in CE(\mathbb{I}, \rho_B) \) be the corresponding trajectory from \( \mathbb{I} \) to \( \rho_B \) with \( (\rho_{1B}, m_{1B})(t, \cdot) := (\rho_{A,B} - m_{B,B})(1 - t, \cdot) \). Then, for \( \delta \in (0, \frac{1}{2}) \) and \( \epsilon = \delta^2 \) we define
\[
\rho_{\delta}(t) = \begin{cases} 
(1 - \epsilon) \cdot \rho_A + \epsilon \cdot \rho_{A,B}(t/\delta) & \text{for } t \in [0, \delta), \\
(1 - \epsilon) \cdot \rho_A + \epsilon \cdot (1 - \delta)/(1 - 2\delta) + \epsilon \cdot \mathbb{I} & \text{for } t \in [\delta, 1 - \delta), \\
(1 - \epsilon) \cdot \rho_B + \epsilon \cdot \rho_{1B}(t - (1 - \delta))/\delta & \text{for } t \in [1 - \delta, 1] 
\end{cases}
\]
and
\[
m_{\delta}(t) = \begin{cases} 
\epsilon \cdot \delta^{-1} \cdot m_{A,B}(t/\delta) & \text{for } t \in [0, \delta), \\
(1 - \epsilon) \cdot (1 - 2\delta)^{-1} \cdot m((t - \delta)/(1 - 2\delta)) & \text{for } t \in [\delta, 1 - \delta), \\
\epsilon \cdot \delta^{-1} \cdot m_{1B}((t - (1 - \delta))/\delta) & \text{for } t \in [1 - \delta, 1]. 
\end{cases}
\]
Next, we discretize in time. Since \( \rho_s \)

In view of (14), it remains to estimate \( \rho_{m_h} \) we decompose it into the contributions of the time intervals \( I_l = [0, \delta], I_m = [\delta, 1 - \delta] \) and \( I_r = [1 - \delta, 1] \):

\[
\mathcal{A}(\rho_{0}, \rho_{m}) = \mathcal{A}_t + \mathcal{A}_m + \mathcal{A}_r \quad \text{with} \quad \mathcal{A}_x = \int_{I_x} \mathcal{A}_{\text{int}}(\rho_{0}(t), m_{\delta}(t)) \, dt \quad \text{for} \quad x \in \{l, m, r\}.
\]

where

\[
\mathcal{A}_{\text{int}} : \mathbb{R}^{X} \times \mathbb{R}^{X} \to \mathbb{R} \cup \{\infty\}, \quad (\rho, m) \mapsto \frac{1}{2} \sum_{x \in X} a(\rho(x), \rho(y), m(x, y)) \, Q(x, y) \, \pi(x).
\]

\( \mathcal{A}_{\text{int}} \) is jointly convex and 1-homogeneous and therefore sub-additive. Moreover, it is 2-homogeneous in the second argument. We therefore obtain

\[
\mathcal{A}_m \leq \frac{(1 - \varepsilon)}{(1 - 2\delta)^2} \int_{I_m} \mathcal{A}_{\text{int}}(\rho((t - \delta)/(1 - 2\delta)), m((t - \delta)/(1 - 2\delta))) \, dt = \frac{(1 - \varepsilon)}{(1 - 2\delta)} \mathcal{A}_m(\rho, m).
\]

Further, using Proposition 3.3 we obtain \( \mathcal{A}_t + \mathcal{A}_r \leq 2C(X) \delta \).

Next, we discretize in time. Since \( \rho \in C^{0,\frac{1}{2}}([0, 1], \mathbb{R}^{X}) \) we have \( |\rho(t, x) - \rho(t', x)| \leq g(|t - t'|) \) with \( g(s) := C \cdot s^{\frac{1}{2}} \) for all \( x \in X \). Now let \( \Lambda = g(2h) \) and choose the regularization parameter \( \delta = \min\{i : i \in \mathbb{N}, i \cdot h \geq \Lambda^2\} \) and as before \( \epsilon = \delta^2 \). Obviously \( \Lambda, \delta \) and \( \epsilon \to 0 \) as \( h \to 0 \). In particular, for \( h \) sufficiently small \( 2 \geq 1/(1 - 2\delta) \) and thus \( \Lambda = g(2h) \geq g(h/(1 - 2\delta)) \). Therefore, \( \Lambda \) is a uniform upper bound for the variation of \( \rho_0 \) on any interval of the size \( h \). We now set

\[
\rho_h = I_h \rho_0, \quad m_h = \text{avg}_{\rho_0} m_0,
\]

and note that \( (\rho_h, m_h) \in CE_h(\rho_A, \rho_B) \). As \( \delta \to 0 \) one finds \( (\rho_h, m_h) \rightharpoonup (\rho, m) \) and for \( h \to 0 \) we obtain \( (\rho_h - \rho_0, m_h - m_0) \rightharpoonup 0 \). This implies that \( (\rho_h, m_h) \rightharpoonup (\rho, m) \).

Note that \( \delta \) was chosen to be an integer multiple of \( h \). So the division of \( [0, 1] \) into the three intervals \( [0, \delta], [\delta, 1 - \delta] \) and \( [1 - \delta, 1] \) in the construction of \( (\rho_h, m_h) \) is compatible with the grid discretization of step size \( h \). Therefore, as above, the discrete action decomposes into three contributions which we denote \( \mathcal{A}_h(\rho_h, m_h) = \mathcal{A}_{lh} + \mathcal{A}_{mh} + \mathcal{A}_{rh} \). Again, using joint 1-homogeneity and sub-additivity of \( a \), as well as the 2-homogeneity in the second argument one obtains

\[
\mathcal{A}_{lh} \leq \frac{\varepsilon}{\delta} \cdot \mathcal{A}_h(I_h \rho_{A,1}, \text{avg}_{\rho_0} m_{A,1}), \quad \mathcal{A}_{mh} \leq \frac{\varepsilon}{\delta} \cdot \mathcal{A}_h(I_h \rho_{1,0}, \text{avg}_{\rho_0} m_{1,0}).
\]

Using Proposition 3.3 we observe that

\[
\mathcal{A}_{lh} + \mathcal{A}_{rh} \leq 2C(X) \delta.
\]

In view of (14), it remains to estimate \( \mathcal{A}_{mh} \) by a suitable constant times \( \mathcal{A}_m \). To this end, let \( S_m \subset \{0, \ldots, N - 1\} \) the set of discrete indices such that \( I_l \subset I_m \) for \( i \in S_m \). Then \( \mathcal{A}_m \) is given by

\[
\mathcal{A}_m = \frac{1}{2} \sum_{i \in S_m} \sum_{x \in X} \int_{I_l} a(\rho_0(t, x), \rho_0(t, y), m_h(t, x, y)) \, dt \, Q(x, y) \, \pi(x).
\]
Since $\alpha$ is convex, by Jensen’s inequality one finds
\[ \int_t \alpha(\rho(t,x),\rho(t,y),m(t,x,y))\, dt \geq h \cdot \alpha((\text{avg}_h \rho_h)(t,i,x),(\text{avg}_h \rho_h)(t,i,y),(\text{avg}_h m_h)(t,i,x,y)). \]

The discretized action $\mathcal{A}_{mh}$ is a weighted sum of the form
\[ \mathcal{A}_{mh} = \frac{1}{2} \sum_{i \in S_m} \sum_{x \in X} h \cdot \alpha((\text{avg}_h I_h \rho_h)(t_i,x),(\text{avg}_h I_h \rho_h)(i,y),\text{avg}_h m_h)(t_i,x,y)) \cdot Q(x,y) \pi(x). \]

By construction $\rho_h$ is bounded from below by $\epsilon$ on $I_m$ on all nodes and its variation within each discretization interval is bounded by $\Delta$. Therefore, for any $i \in S_m, z \in X$ one finds
\[ (\text{avg}_h \rho_h)(t_i,z) \leq (\text{avg}_h I_h \rho_h)(t_i,z) + \Delta, \quad (\text{avg}_h I_h \rho_h)(t_i,z) \geq \epsilon. \]

Due to the monotonicity of $s \rightarrow \frac{s}{s+\epsilon}$ we obtain
\[ \frac{(\text{avg}_h I_h \rho_h)(t_i,z)}{(\text{avg}_h \rho_h)(t_i,z)} \geq \frac{(\text{avg}_h I_h \rho_h)(t_i,z)}{(\text{avg}_h I_h \rho_h)(t_i,z) + \Delta} \geq \frac{\epsilon}{\epsilon + \Delta}. \]

Taking into account the joint 1-homogeneity of $\theta$ and the monotonicity of $\theta$ in each single argument this implies for all $x, y \in X$ that
\[ \frac{\theta((\text{avg}_h I_h \rho_h)(t_i,x),(\text{avg}_h I_h \rho_h)(t_i,y))}{\theta((\text{avg}_h \rho_h)(t_i,x),(\text{avg}_h \rho_h)(t_i,y))} \geq \frac{\epsilon}{\epsilon + \Delta} = \frac{1}{1 + \Delta/\epsilon}. \]

Hence,
\[ \mathcal{A}_{mh} = \frac{1}{2} \sum_{i \in S_m} \sum_{x \in X} h \cdot \frac{(\text{avg}_h m_h)^2(t_i,x,y)}{\theta((\text{avg}_h I_h \rho_h)(t_i,x),(\text{avg}_h I_h \rho_h)(t_i,y))} Q(x,y) \pi(x) \leq \frac{1}{2} (1 + \Delta/\epsilon) \sum_{i \in S_m} \sum_{x \in X} h \cdot \frac{(\text{avg}_h m_h)^2(t_i,x,y)}{\theta((\text{avg}_h \rho_h)(t_i,x),(\text{avg}_h \rho_h)(t_i,y))} Q(x,y) \pi(x) = (1 + \Delta/\epsilon) \mathcal{A}_m. \]

Our choice of $\delta$ implies that $\epsilon = \delta^2 \geq \Delta^2$ and thus $\Delta/\epsilon \leq \epsilon$. Altogether, we obtain for $h$ sufficiently small
\[ \mathcal{A}_h(\rho_h, m_h) = \mathcal{A}_{lh} + \mathcal{A}_{mh} + \mathcal{A}_{ch} \leq 2 C(X) \delta + (1 + \epsilon) \frac{1 - \epsilon}{1 - 2 \epsilon} \mathcal{A}(\rho, m). \]

Since $\delta \to 0, \epsilon \to 0$ as $h \to 0$, this establishes the $\Gamma$-lim sup property.

Next, we establish convergence of the discrete optimizers to a continuous solution. To establish compactness we first show a uniform bound for the $L^2$ norm of the discrete momenta, in analogy to Lemma 2.5.

**Lemma 3.7** ($L^2$ bound for the discrete momentum). Let $(\rho_h, m_h) \in V_{n,h}^1 \times V_{c,h}^0$ with discrete energy $E_h(\rho_h, m_h) \leq \bar{E} < \infty$. Then, there exists a constant $\bar{M} < \infty$ only depending on $(X, Q, \pi)$ and $\bar{E}$ (and not on $h$), such that $||m_h||_{L^2((0,1),\mathcal{H}^n \times X)} \leq \bar{M}$. 

12
Proof. The proof works in complete analogy to Lemma 2.5. We bound

\[
\left( \sum_{x,y \in \mathcal{X}} |m_h(t_i, x, y)| Q(x, y) \pi(x) \right)^2 \leq \left( \sum_{x,y \in \mathcal{X}} \alpha(\text{avg}_h \rho_h(t_i, x), \text{avg}_h \rho_h(t_i, y), m(t_i, x, y)) Q(x, y) \pi(x) \right) 
\]

and

\[
\sum_{x,y \in \mathcal{X}} \theta(\text{avg}_h \rho_h(t_i, x), \text{avg}_h \rho(t_i, y)) Q(x, y) \pi(x) \leq C^*,
\]

where \( C^* \) is defined in (7). Here, we have used that \((\rho_h, m_h) \in CE(\rho_A, \rho_B) \) which implies that mass is preserved, i.e. \( \sum_{x \in \mathcal{X}} \text{avg}_h \rho_h(t_i, x) \pi(x) = \sum_{x \in \mathcal{X}} \rho_h(t_i, x) \pi(x) = \sum_{x \in \mathcal{X}} \rho_A(x) \pi(x) = 1 \) for all \( i = 0, \ldots, N - 1 \), and that since \( \mathcal{A}_h(\rho_h, m_h) < \infty \) one has \( \text{avg}_h \rho_h \geq 0 \). Now, once more using that \( \mathcal{X} \) is finite and integrating (or summing) in time establishes the bound. \( \square \)

**Theorem 3.8** (Convergence of discrete geodesics). For fixed temporal boundary conditions \( \rho_A, \rho_B \) any sequence \((\rho_h, m_h) \) of minimizers of \( E_h \) is uniformly bounded in \( C^{1/2}([0,1], \mathbb{R}^X) \times L^2((0,1), \mathbb{R}^{X \times X}) \) for \( h \to 0 \). Up to selection of a subsequence, \( \rho_h \to \rho \) strongly in \( C^{0,0}([0,1], \mathbb{R}^X) \) for any \( \alpha \in [0, \frac{1}{2}] \) and \( m_h \to m \) weakly in \( L^2 \) with \( (\rho, m) \) being a minimizer of the energy \( E \).

**Proof.** For a sequence of minimizers \((\rho_h, m_h) \) the discrete energy \( E_h(\rho_h, m_h) \) is uniformly bounded by Corollary 3.4. Since \((\rho_h, m_h) \in CE(\rho_A, \rho_B) \) the total variation of all \( \rho_h \) is uniformly bounded. Further, by Lemma 3.7 the \( L^2 \) norm \( \|m_h\|_{L^2([0,1], \mathbb{R}^{X \times X})} \) is uniformly bounded. Hence, the sequence \((\rho_h, m_h) \) has a weakly* (in the sense of measures) convergent subsequence, which by Theorem 3.6 and a standard consequence of \( \Gamma \) convergence theory converges weakly* to some minimizer \((\rho, m) \) of \( E \).

Using the continuity equation this convergence can be strengthened. We already know that \((\rho_h, m_h) \) solves the continuity equation \( \partial_t \rho_h = -\text{div}_X m_h \). Thus, the uniform bound for \( m_h \) in \( L^2((0,1), \mathbb{R}^{X \times X}) \) implies that \( \rho_h \) is uniformly bounded in \( H^{1,2}(\mathbb{R}^X) \). From this we obtain by the Sobolev embedding theorem that \((\rho_h, m_h) \) is uniformly bounded in \( C^{0,\frac{1}{2}}(\mathbb{R}^X) \) and compact in \( C^{0,\alpha}(\mathbb{R}^X) \) for all \( \alpha \in [0, \frac{1}{2}] \). \( \square \)

## 4 Optimization with Proximal Splitting

### 4.1 Slack Variables and Proximal Splitting

The computation of the discrete transportation distance (11) and the associated transport path require the solution of a finite-dimensional non-smooth convex optimization problem. To this end, we apply a proximal splitting approach with suitably chosen slack variables. The proximal mapping of a convex and lower semi-continuous function \( f : H \to \mathbb{R} \cup \{\infty\} \) on a Hilbert space \( H \) with norm \( \| \cdot \|_H \) is defined as

\[
\text{prox}_f(x) = \arg \min_{y \in H} \frac{1}{2} \|x - y\|_H^2 + f(y).
\]  

(14)
Furthermore, the indicator function of a closed convex set $K \subset H$ is given by $I_K(x) = 0$ for $x \in K$ and $\infty$ elsewise. In particular, $\text{prox}_{f_K} = \text{proj}_K$, where $\text{proj}_K$ is the projection onto $K$. For a function $f : H \mapsto \mathbb{R} \cup \{\infty\}$ its Fenchel conjugate is given by
\[
f^*(y) = \sup_{x \in H} \langle y, x \rangle_H - f(x) .
\]

If $f(x) < \infty$ for some $x \in H$, then $f^*$ is convex and lower semi-continuous. For more details and an introduction to convex analysis see e.g. [BC11]. The practical applicability of proximal splitting schemes depends on whether the objective can be split into terms such that the proximal mapping for each term can be computed efficiently. In [PPO14] a spatiotemporal discretization with staggered grids of the classical Benamou–Brenier formulation [BB00] of optimal transport of Lebesgue densities on $\mathbb{R}^n$ was presented and several proximal splitting methods were considered to solve the discrete problem. However, this approach can not directly be transferred to problem (11) since the action $\mathcal{A}$ couples the variables $\rho$ and $m$ in a non-linear way via the terms $\alpha(m(t_i, x), \text{avg}_h \rho(t_i, x), \text{avg}_h \rho(t_i, y)))$ spatially over the whole graph according to the transition kernel $Q$ and temporally via the averaging operator $\text{avg}_h$. Thus, the proximal mapping of the $\mathcal{A}$-term is not separable in space or time and thus requires the solution of a fully coupled, nonlinear minimization problem. As a remedy, we propose to introduce auxiliary variables to decouple the variables and rewrite the action $\mathcal{A}$ with terms where variables only interact locally, thus leading to separable, hence simpler, proximal mappings.

**Lemma 4.1.** For $(\rho, m) \in V^1_{n,h} \times V^0_{e,h}$ one finds
\[
\mathcal{A}_h(\rho, m) = \mathcal{A}(\text{avg}_h \rho, m) = \inf \left\{ \mathcal{\hat{A}}(\delta, m) + I_{\mathcal{K}_\rho}(\text{avg}_h \rho, \delta) : \delta \in V^0_{e,h} \right\}
\]
with the convex set
\[
\mathcal{K}_\rho := \left\{ (\rho, \delta) \in V^0_{n,h} \times V^0_{e,h} : 0 \leq \delta(t_i, x, y) \leq \theta(\rho(t_i, x), \rho(t_i, y)) \forall i = 0, \ldots, N - 1, \forall x, y \in X \right\}
\]
and the edge-based action
\[
\mathcal{\hat{A}}(\delta, m) := \frac{1}{2} \int_0^1 \sum_{x,y \in X} \Phi(\delta(t, x, y), m(t, x, y)) Q(x, y) \pi(x) \, \text{d}t
\]
with
\[
\Phi(\delta, m) := \begin{cases} \frac{\delta^2}{2} & \text{if } \delta > 0, \\ 0 & \text{if } (m, \delta) = (0, 0), \\ +\infty & \text{else.} \end{cases}
\]

Note that $\Phi$ is the integrand of the Benamou–Brenier action functional and that $\alpha(s, t, m) = \Phi(\theta(s, t), m)$.

**Proof.** The first equality is merely the definition of $\mathcal{A}_h$ and using the fact that $\text{avg}_h m = m$ for $m \in V^0_{e,h}$. For the second equality note that for any $\delta \in V^0_{e,h}$ with $(\rho, \delta) \in \mathcal{K}_{\rho}$ one has $\delta(t_i, x, y) \leq \theta(\rho(t_i, x), \rho(t_i, y))$. By monotonicity of $\Phi$ in its first argument this implies $\Phi(\delta(t_i, x, y), m(t_i, x, y)) \geq \alpha(\rho(t_i, x), \rho(t_i, y), m(t_i, x, y))$ and hence
\[
\mathcal{A}(\rho, m) \leq \inf \left\{ \mathcal{\hat{A}}(\delta, m) + I_{\mathcal{K}_\rho}(\rho, \delta) : \delta \in \mathbb{R}^{X \times X} \right\} .
\]

Further, we obviously have that $\delta(t_i, x, y) := \theta(\rho(t_i, x), \rho(t_i, y))$ satisfies $(\rho, \delta) \in \mathcal{K}_\rho$ and $\mathcal{\hat{A}}(\delta, m) = \mathcal{A}(\rho, m)$. Hence, we have equality in (19). \qed

14
The proximal mapping of the function $\hat{A}$ can be computed separately for each time interval and graph edge. However, the set $\mathcal{K}_{\text{pre}}$ still couples the variables $\text{avg}_h \rho$ and $\hat{\theta}$ according to the graph structure and the averaging operator $\text{avg}_h$ couples the variables of $\rho$ in time. To resolve this, we introduce a second set of auxiliary variables.

**Lemma 4.2.** For $\rho \in \mathbb{R}^K$, $\hat{\theta} \in \mathbb{R}^{K \times K}$ one finds

$$I_{\mathcal{K}_{\text{pre}}}(\text{avg}_h \rho, \hat{\theta}) = \inf \left\{ I_{\mathcal{J}_{\text{avg}}}(\rho, \rho) + I_{\mathcal{J}_-}(\rho, q) + I_{\mathcal{J}_+}(q, \rho^-, \rho^+) + I_{\mathcal{K}}(\rho^-, \rho^+, \hat{\theta}) : \right.$$

$$(\rho, q, \rho^-, \rho^+) \in (V_{n,h}^0)^2 \times (V_{n,h}^0)^2 \right\}$$

where

$$\mathcal{J}_{\text{avg}} := \left\{ (\rho, \rho) \in V_{n,h}^1 \times V_{n,h}^0 : \rho = \text{avg}_h \rho \right\},$$

$$\mathcal{J}_- := \left\{ (\rho, q) \in (V_{n,h}^0)^2 : \rho = q \right\},$$

$$\mathcal{J}_+ := \left\{ (q, \rho^-, \rho^+) \in V_{n,h}^0 \times (V_{n,h}^0)^2 : q(t, x) = \rho^-(t, x, y), q(t, y) = \rho^+(t, x, y) \right\},$$

$$\mathcal{K} := \left\{ (\rho^-, \rho^+, \hat{\theta}) \in (V_{n,h}^0)^3 : \rho^-(t, x, y), \rho^+(t, x, y), \hat{\theta}(t, x, y) \in K \right\}.$$  

with

$$K := \{ (\rho^-, \rho^+, \hat{\theta}) \in \mathbb{R}^3 : 0 \leq \hat{\theta} \leq \Theta(\rho^-, \rho^+) \}.$$  

**Proof.** For fixed $\rho \in V_{n,h}^1$ there is precisely one tuple $(\rho, q, \rho^-, \rho^+)$ such that

$$(\rho, \rho) \in \mathcal{J}_{\text{avg}}, \quad (\rho, q) \in \mathcal{J}_- \quad \text{and} \quad (q, \rho^-, \rho^+) \in \mathcal{J}_+,$$

given by $\rho = \text{avg}_h \rho$, $q = \rho$, $\rho^-(t, x, y) = q(t, x)$, $\rho^+(t, x, y) = q(t, y)$. For this $(\rho^-, \rho^+, \hat{\theta})$ one finds $(\rho^-, \rho^+, \hat{\theta}) \in \mathcal{K}$ if and only if $(\text{avg}_h \rho, \hat{\theta}) \in \mathcal{K}_{\text{pre}}$. \hfill \Box

The function $I_{\mathcal{J}_{\text{avg}}}$ relates the values of $\rho$ on time nodes to the average values on the adjacent time intervals, $I_{\mathcal{J}_-}$ communicates the values of $q$ on graph nodes to the adjacent graph edges and $I_{\mathcal{K}}$ ensures the mass averaging via the function $\hat{\theta}$. The additional splitting via $I_{\mathcal{J}_+}$ will later simplify partition of the final optimization problem into primal and dual component. The sets $\mathcal{J}_{\text{avg}}, \mathcal{J}_-, \mathcal{J}_+ \quad \text{and} \quad \mathcal{K}$ are all products of simpler low-dimensional sets, implying simpler computation of the relevant proximal mappings and projections.

This gives us an equivalent formulation for the discrete minimization problem (11):

$$W_h(\hat{\rho}_A, \hat{\rho}_B)^2 = \inf \left\{ (\mathcal{F} + \mathcal{G})(\rho_h, m_h, \hat{\theta}_h, \rho_h^-, \rho_h^+, \rho_h, q_h) : \right.$$  

$$(\rho_h, m_h, \hat{\theta}_h, \rho_h^-, \rho_h^+, \rho_h, q_h) \in V_{n,h}^1 \times (V_{n,h}^0)^4 \times (V_{n,h}^0)^2 \right\}$$

with

$$\mathcal{F}(\rho_h, m_h, \hat{\theta}_h, \rho_h^-, \rho_h^+, \rho_h, q_h) := \hat{A}(\hat{\theta}_h, m_h) + I_{\mathcal{J}_-}(q_h, \rho_h^-, \rho_h^+) + I_{\mathcal{J}_{\text{avg}}}(\rho_h, \rho_h),$$

$$\mathcal{G}(\rho_h, m_h, \hat{\theta}_h, \rho_h^-, \rho_h^+, \rho_h, q_h) := I_{\mathcal{C}E_h(\rho_h, m_h)}(\rho_h, m_h) + I_\mathcal{K}(\rho_h^-, \rho_h^+, \hat{\theta}_h) + I_{\mathcal{J}_+}(\rho_h, q_h).$$

15
The structure of this optimization problem is well suited for the first order primal-dual algorithm presented in [CP11]. We consider the Hilbert space $H = V_{t,h}^1 \times (V_{t,h}^0)^4 \times (V_{n,h}^0)^2$ composed of tuples of functions in space and time with the scalar product

$$\langle \left( \rho_{h,1}, m_{h,1}, \delta_{h,1}, \rho_{h,1}^+, \rho_{h,1}^- \right), \left( \rho_{h,2}, m_{h,2}, \delta_{h,2}, \rho_{h,2}^+, \rho_{h,2}^- \right) \rangle_H$$

\[ := h \sum_{i=0}^{N-1} \langle \rho_{h,1}(t_i, \cdot), \rho_{h,1}^+(t_i, \cdot) \rangle_{\pi} + h \sum_{i=0}^{N-1} \langle \rho_{h,2}(t_i, \cdot), \rho_{h,2}^+(t_i, \cdot) \rangle_{\pi} + \langle q_{h,1}(t_i, \cdot), q_{h,2}(t_i, \cdot) \rangle_{\pi} \]

\[ + h \sum_{i=0}^{N-1} \langle m_{h,1}(t_i, \cdot), m_{h,2}(t_i, \cdot) \rangle_{Q} + \langle \delta_{h,1}(t_i, \cdot), \delta_{h,2}(t_i, \cdot) \rangle_{Q} \]

\[ + h \sum_{i=0}^{N-1} \langle \rho_{h,1}^-(t_i, \cdot), \rho_{h,2}^-(t_i, \cdot) \rangle_{Q} + \langle \rho_{h,1}^+(t_i, \cdot), \rho_{h,2}^+(t_i, \cdot) \rangle_{Q} . \]  

(27)

and the induced norm denoted by $\| \cdot \|_H$. Then applying [CP11, Algorithm 1] to solve problem (26) with $\mathcal{F}, \mathcal{G} : H \to \mathbb{R} \cup \{ \infty \}$ amounts to iteratively compute for initial data $(a^{(0)}, b^{(0)}) \in H^2$ and $\tilde{a}^{(0)} = a^{(0)}$:

\[ b^{(l+1)} = \text{prox}_{\mathcal{F}} \left( b^{(l)} + \sigma \tilde{a}^{(l)} \right), \]

\[ a^{(l+1)} = \text{prox}_{\mathcal{G}} \left( a^{(l)} - \tau b^{(l+1)} \right), \]

\[ \tilde{a}^{(l+1)} = \tilde{a}^{(l+1)} + \lambda \cdot \left( a^{(l+1)} - a^{(l)} \right). \]  

(28)

where $\tau, \sigma > 0$, $\lambda \in [0, 1]$. As demonstrated in [CP11] the iterates converge to a minimizer in (26) if $\tau \cdot \sigma < 1$. For some $(\rho_h, m_h, \delta_h, \rho_h^+, \rho_h^-, \bar{\rho}_h, q_h) \in H$ one finds

$$\mathcal{F}^*(\rho_h, m_h, \delta_h, \rho_h^+, \rho_h^-, \bar{\rho}_h, q_h) = \mathcal{F}^*(\delta_h, m_h) + \mathcal{J}_{d}^*(q_h, \rho_h^+, \rho_h^-) + \mathcal{J}_{d,e}^*(\rho_h, \bar{\rho}_h)$$

and the proximal mapping $(\rho_{h}^{pr}, m_{h}^{pr}, \delta_{h}^{pr}, \rho_{h}^{pr^+}, \rho_{h}^{pr^-}, \bar{\rho}_{h}^{pr}, q_{h}^{pr}) = \text{prox}_{\mathcal{F}} \mathcal{G}^*(\rho_h, m_h, \delta_h, \rho_h^+, \rho_h^-, \bar{\rho}_h, q_h)$ decomposes as follows:

$$\left( \delta_{h}^{pr}, m_{h}^{pr} \right) = \text{prox}_{\mathcal{F}} \mathcal{G}^*(\delta_h, m_h),$$

$$\left( q_{h}^{pr^-}, \rho_{h}^{pr+}, \rho_{h}^{pr^-} \right) = \text{prox}_{\mathcal{F}} \mathcal{G}^*(q_h, \rho_h^+, \rho_h^-),$$

$$\left( \rho_{h}^{pr^+}, \rho_{h}^{pr^-} \right) = \text{prox}_{\mathcal{F}} \mathcal{G}^*(\rho_h, \bar{\rho}_h).$$

Likewise, for $(\rho_{h}^{pr}, m_{h}^{pr}, \delta_{h}^{pr}, \rho_{h}^{pr^+}, \rho_{h}^{pr^-}, \bar{\rho}_{h}^{pr}, q_{h}^{pr}) = \text{prox}_{\mathcal{F}} \mathcal{G}^*(\rho_h, m_h, \delta_h, \rho_h^+, \rho_h^-, \bar{\rho}_h, q_h)$ one finds

$$\left( \rho_{h}^{pr^+}, m_{h}^{pr^-} \right) = \text{proj}_{\mathcal{C}_{d}(\rho_{h}, \rho_{h})} \left( \rho_h, m_h \right),$$

$$\left( \rho_{h}^{pr^-}, \delta_{h}^{pr^+}, \rho_{h}^{pr^-} \right) = \text{proj}_{\mathcal{C}_{d,e}(\rho_{h}, \rho_{h}^+)} \left( \rho_h^+, \rho_h^- \right),$$

$$\left( \rho_{h}^{pr}, q_{h}^{pr} \right) = \text{proj}_{\mathcal{C}_{d,e}(\rho_{h}, q_{h})} \left( \rho_h, q_h \right).$$

Each of the proximal maps is performed with respect to the norm $\| \cdot \|_H$ restricted to the relevant variables.

In what follows, we will study these maps in detail. In fact, we will observe that $\text{prox}_{\mathcal{F}} \mathcal{G}^*$ and $\text{proj}_{\mathcal{F}}$ can be separated into low-dimensional problems over each time-step and edge $(x, y) \in X \times X$, $\text{prox}_{\mathcal{F}} \mathcal{G}^*$ splits into low-dimensional problems for each time-step and node $x \in X$, $\text{prox}_{\mathcal{F}}$
where $CE$ is well-suited to solve (26).

For given $(\rho_{h}, m_{h}) \in V_{n,h}^{1} \times V_{c,h}^{0}$ we need to solve the following problem:

$$
\text{proj}_{CE_{h}(\rho_{A}, \rho_{B})}(\rho_{h}, m_{h}) = \arg \min_{(\rho_{h}^{pr}, m_{h}^{pr}) \in CE_{h}(\rho_{A}, \rho_{B})} \frac{h}{2} \sum_{i=0}^{N} |\rho_{h}^{pr}(t_{i}, \cdot) - \rho_{h}(t_{i}, \cdot)|_{\pi}^{2} + \frac{h}{2} \sum_{i=0}^{N-1} ||m_{h}^{pr}(t_{i}, \cdot) - m_{h}(t_{i}, \cdot)||_{Q}^{2} \tag{29}
$$

To this end we take into account the following dual formulation.

**Proposition 4.3.** The solution $(\rho_{h}^{pr}, m_{h}^{pr})$ to (29) is given by

$$
\begin{align*}
\rho_{h}^{pr}(t_{i}, x) &= \rho_{h}(t_{i}, x) + \frac{q_{h}(t_{i}, x) - q_{h}(t_{i-1}, x)}{h}, \quad \forall i = 1, \ldots, N - 1, \tag{30a} \\
\rho_{h}^{pr}(t_{0}, x) &= \rho_{A}(x), \quad \rho_{h}^{pr}(t_{N}, x) = \rho_{B}(x), \tag{30b} \\
m_{h}^{pr}(t_{i}, x, y) &= m_{h}(t_{i}, x, y) + \nabla_{x}q_{h}(t_{i}, x, y), \quad \forall i = 1, \ldots, N - 1. \tag{30c}
\end{align*}
$$

where $q_{h}$ solves the space time elliptic equation

$$
\begin{align*}
\pi(x)\frac{q_{h}(t_{1}, x) - q_{h}(t_{0}, x)}{h^2} + \pi(x)\Delta_{n}q_{h}(t_{0}, x) &= -\pi(x) \left( \frac{p_{h}(t_{1}, x) - \rho_{A}(x)}{h} + \text{div}m_{h}(t_{0}, x) \right), \\
pi(x)\frac{-q_{h}(t_{N-1}, x) + q_{h}(t_{N-2}, x)}{h^2} + \pi(x)\Delta_{n}q_{h}(t_{N-1}, x) &= -\pi(x) \left( \frac{p_{B}(x) - q_{h}(t_{N-1}, x)}{h} + \text{div}m_{h}(t_{N-1}, x) \right) \\
\pi(x)\frac{q_{h}(t_{i+1}, x) - 2q_{h}(t_{i}, x) + q_{h}(t_{i-1}, x)}{h^2} + \pi(x)\Delta_{n}q_{h}(t_{i}, x) &= -\pi(x) \left( \frac{p_{h}(t_{i+1}, x) - \rho_{B}(t_{i}, x)}{h} + \text{div}m_{h}(t_{i}, x) \right) \\
\end{align*}
$$

for $i = 1, \ldots, N - 2$ and $x \in \mathcal{X}$.

The factors $\pi(x)$ in (31) could be canceled but they will simplify further analysis.

**Proof.** We define the Lagrangian corresponding to (29) as

$$
L[p_{h}^{pr}, m_{h}^{pr}, q_{h}, \lambda_{A}, \lambda_{B}] = \frac{h}{2} \sum_{i=0}^{N} |p_{h}^{pr}(t_{i}, \cdot) - \rho_{h}(t_{i}, \cdot)|_{\pi}^{2} + \frac{h}{2} \sum_{i=0}^{N-1} ||m_{h}^{pr}(t_{i}, \cdot) - m_{h}(t_{i}, \cdot)||_{Q}^{2}
$$

$$
+ h \sum_{i=0}^{N-1} \sum_{x \in \mathcal{X}} q_{h}(t_{i}, x) \left( \frac{p_{h}^{pr}(t_{i+1}, x) - p_{h}^{pr}(t_{i}, x)}{h} + \text{div}m_{h}^{pr}(t_{i}, x) \right) \pi(x)
$$

$$
+ \sum_{x \in \mathcal{X}} \lambda_{A}(x)(p_{h}(t_{N}, x) - \rho_{B}(x)) + \lambda_{A}(x)(p_{h}(t_{0}, x) - \rho_{A}(x)) \pi(x)
$$

17
where $\lambda_A, \lambda_B$ are the Lagrange multipliers for the boundary conditions $\rho_B(t_0, \cdot) = \rho_{A, \rho_B}(t_N, \cdot) = \rho_B$. The optimality condition in $\rho_B$ and $m_B$ directly imply (30a) and (30c). (30b) reflects the boundary conditions, which are to be ensured in $CE_A(\rho_A, \rho_B)$. Inserting these relations into the continuity equation $\partial_t \rho_B + \text{div} m_B = 0$ leads to the system of equations (31).

The Lagrange multiplier $\varphi_S$ in Proposition 4.3 lives in $V^0_{u,h}$ which can be identified with $\mathbb{R}^{N_{\text{card}} X}$. We equip this space with the canonical basis

$$(p^x_S)_{i=0, \ldots, N-1, x \in X} \quad \text{where} \quad (p^x_S(t, y)) = \delta_{ij} \cdot \delta_{x,y}$$

and the standard Euclidean inner product with respect to this basis. Then the elliptic equation (31) can be written as a linear system $SZ = F$ for a coordinate vector $Z = (\varphi_S(t, x))_{t=0, \ldots, N-1, x \in X}$, a matrix $S \in \mathbb{R}^{(N_{\text{card}} X) \times (N_{\text{card}} X)}$ and a vector $F \in \mathbb{R}^{N_{\text{card}} X}$. The matrix $S$ is symmetric since $\pi(x)Q(x, y) = \pi(y)Q(y, x)$ and the matrix representation of $\triangle_X$ is $Q = \text{diag}(\sum_y Q(\cdot, y))$. Furthermore, $S$ is sparse if $Q$ is sparse. However, the matrix $S$ is not invertible, its kernel is spanned by functions that are constant in space and time. To see this, assume that a non constant $Z$ is in the kernel of $S$ and denote by $\varphi_S$ the associated vector in $V^0_{u,h}$. Now, let $I_+(\mu) := \{(i, x) \in \{0, \ldots, N-1\} \times X : \varphi_S(i, x) > \mu \}$ for $\mu = \min \varphi_S(i, x)$ and define $\psi_S \in V^0_{u,h}$ via $\psi_S(t, x) = 1$ if $(i, x) \in I_+(\mu)$ and $\psi_S(t, x) = 0$ else. Let $W$ be the associated nodal vector to $\psi_S$. By assumption on $Z$, the set $I_+(\mu)$ is non empty and thus it is easy to see that $W^T SZ < 0$ and $Z$ can not be in the kernel of $S$, which proves the claim.

We impose the additional constraint $\sum_{i=0}^{N-1} \sum_{x \in X} \varphi_S(i, x) = 0$ to remove this ambiguity. This can be written as $w^T \varphi_S = 0$ where $w \in \mathbb{R}^{N_{\text{card}} X}$ is the vector with entries $w^x = 1$ leading to the linear system

$$\begin{pmatrix} S & w^T & 0 \\ w^T & 0 & \end{pmatrix} \begin{pmatrix} Z \\ \lambda \end{pmatrix} = \begin{pmatrix} F \\ 0 \end{pmatrix}.$$

This system is uniquely solvable and the solution implies $\lambda = 0$ if $F \perp w$ (in the Euclidean sense), which is true because $\rho_A$ and $\rho_B$ are assumed to be of equal mass.

### 4.3 Proximal Mapping of $\hat{A}^*$

The function $\hat{A}$ is convex and 1-homogeneous, hence its Fenchel conjugate is the indicator function of a convex set and the proximal mapping of $\hat{A}^*$ is a projection. For $(\delta, m) \in (V^0_{e,h})^2$ one has

$$\hat{A}(\delta, m) = h \sum_{i=0}^{N-1} \sum_{x, y \in X} \Phi(\delta(t, x, y), m(t, x, y)) Q(x, y) \pi(x).$$

Following [BB00] a direct calculation for $(p, q) \in (V^0_{e,h})^2$ yields

$$\hat{A}^*(p, q) = \sup_{(\delta, m) \in (V^0_{e,h})^2} h \sum_{i=0}^{N-1} \sum_{x, y \in X} \left[ p(t, x, y), \delta(t, x, y) \right] + \left[ q(t, x, y), m(t, x, y) \right] - \frac{1}{2} \sum_{(x, y) \in X \times X} \Phi(\delta(t, x, y), m(t, x, y)) Q(x, y) \pi(x) \right]$$

$$= \frac{h}{2} \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} \sum_{(x, y) \in X \times X} \Phi^*(p(t, x, y), q(t, x, y)) Q(x, y) \pi(x) = \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} J_{\Omega}(p(t, x, y), q(t, x, y))$$

18
with $\Phi^* = I_\mathcal{B}$ for $\mathcal{B} = \{(p, q) \in \mathbb{R}^2 : p + \frac{q}{2} \leq 0\}$. Thus the proximal mapping separates into two-dimensional problems for each time interval and graph edge and $(p^{pr}, q^{pr}) = \text{prox}_{\alpha \tilde{h}^*}(p, q)$ precisely if

$$(p^{pr}(t, x, y), q^{pr}(t, x, y)) = \text{proj}_\mathcal{B}(p(t, x, y), q(t, x, y)),$$

where $\text{proj}_\mathcal{B}$ is the projection with respect to the standard Euclidean distance on $\mathbb{R}^2$ and a Newton scheme in $\mathbb{R}$ can be used to solve for this projection. Since this proximal mapping is a projection, it is in particular independent of the step size $\alpha$.

### 4.4 Projection onto $\mathcal{K}$

For given $(\rho^-, \rho^+, \theta) \in (V^{0}_{ch})^3$ we need to solve

$$\text{proj}_{\mathcal{K}}(\rho^-, \rho^+, \theta) = \arg \min_{(p^{pr}, q^{pr}, \bar{\theta}^{pr}) \in \mathcal{K}} \frac{1}{2} \sum_{i=0}^{N-1} \left( \|p^{pr}(t_i, \cdot) - p^-(t_i, \cdot)\|_Q^2 + \|q^{pr}(t_i, \cdot) - q^+(t_i, \cdot)\|_Q^2 + \|\bar{\theta}^{pr}(t_i, \cdot) - \theta(t_i, \cdot)\|_Q^2 \right).$$

Recall that $\mathcal{K}$ is a product of the tree-dimensional closed convex set $K_i$ as indicated in (24). Therefore $(\rho^{-pr}, \rho^{+pr}, \theta^{pr}) = \text{proj}_{\mathcal{K}}(\rho^-, \rho^+, \theta)$ decouples into the edgewise projection in each time step, i.e.

$$(p^{-pr}(t, x, y), p^{+pr}(t, x, y), \theta^{pr}(t, x, y)) = \text{proj}_{\mathcal{K}}(p^{-pr}(t, x, y), p^{+pr}(t, x, y), \theta^{pr}(t, x, y))$$

where this projection is with respect to the standard Euclidean distance on $\mathbb{R}^3$. Let us denote by $\tilde{\partial}^{+} \theta(x)$ the super-differential of $\theta$ at $x \in \mathbb{R}^3$, which is the analogue of the sub-differential for concave functions. More precisely, $\tilde{\partial}^{+} \theta(x) = -\tilde{\partial}(-\theta)(x)$, where $\tilde{\partial}(-\theta)(x)$ is the sub-differential of the convex function $x \rightarrow -\theta(x)$ at $x$. Then the projection $p^{pr} = \text{proj}_{\mathcal{K}}(p)$ of $p \in \mathbb{R}^3$ is characterized by [BC11, Prop. 6.46]

$$p - p^{pr} \in N_{\mathcal{K}}(p^{pr}) \coloneqq \{z \in \mathbb{R}^3 : \langle z, q - p^{pr} \rangle \leq 0 \ \forall \ q \in \mathcal{K} \},$$

(32)

where $N_{\mathcal{K}}(p^{pr})$ is the normal cone of $\mathcal{K}$ at $p^{pr}$. To solve this inclusion we distinguish the following cases:

**Lemma 4.4.** For an averaging function $\theta : \mathbb{R}^2 \rightarrow \mathbb{R}$ fulfilling the assumptions listed in Section 1 and for $\mathcal{K} := \{ p \in \mathbb{R}^3 : 0 \leq p_3 \leq \theta(p_1, p_2) \}$ the normal cone $N_{\mathcal{K}}(p^{pr})$ for $p^{pr} \in \mathcal{K}$ is given by:

(i) **Trivial projection**: $p = p^{pr} \in \text{int} \mathcal{K} = \{(p_1, p_2, p_3) \in \mathbb{R}^3 : 0 < p_3 < \theta(p_1, p_2) \}$, then $N_{\mathcal{K}}(p^{pr}) = \{0\}$.

(ii) **Projection onto ‘bottom facet’ of $\mathcal{K}$**: $p^{pr} \in (0, +\infty) \times (0, +\infty) \times \{0\}$, then $N_{\mathcal{K}}(p^{pr}) = \{0\} \times \{0\} \times \mathbb{R}_0^-$. 

(iii) **Projection onto coordinate axis**: $p^{pr} = (p_1^{pr}, 0, 0)$ for $p_1^{pr} \in (0, +\infty)$, then $N_{\mathcal{K}}(p^{pr}) = \{0\} \times \mathbb{R}_0^- \times \mathbb{R}_0^- \cup \{(0, q_2, q_3) \in \{0\} \times \mathbb{R}_0^- \times (0, +\infty) : (0, -q_2/q_3) \in \tilde{\partial}^+ \theta(p_1^{pr}, 0)\}$.

Note that $(0, q) \in \tilde{\partial}^+ \theta(p_1^{pr}, 0)$ is equivalent to $q \geq \lim_{q_2 \searrow 0} \tilde{\partial}^+ \theta(p_1^{pr}, 2q)$ and that $\tilde{\partial}^+ \theta(p_1^{pr}, 0)$ is empty if $\lim_{q_2 \searrow 0} \tilde{\partial}^+ \theta(p_1^{pr}, 2q) = \infty$. The analogous representation holds for the second axis.

(iv) **Projection onto origin**: $p^{pr} = (0, 0, 0)$, then $N_{\mathcal{K}}(p^{pr}) = (\mathbb{R}_0^-)^3 \cup \{(q_1, q_2, q_3) \in \mathbb{R}_0^- \times (0, +\infty) : (q_1/q_3, q_2/q_3) \in -\tilde{\partial}^+ \theta(0)\}$. 

19
(v) Projection onto ‘upper surface’ of $K$: $p_{pr} = (p_{pr}^1, p_{pr}^2, \theta(p_{pr}^1, p_{pr}^2))$ for $(p_{pr}^1, p_{pr}^2) \in (0, +\infty)^2$, then

$$N_K(p_{pr}) = \{ \lambda \cdot (-\partial_1 \theta(p_{pr}^1, p_{pr}^2), -\partial_2 \theta(p_{pr}^1, p_{pr}^2), 1) : \lambda \in \mathbb{R}^+ \}.$$ 

Proof. For $p_{pr} \in \text{int} K$ one finds $N_K(p_{pr}) = \{ 0 \}$ and thus $p_{pr} = p$, which implies (i).

In case (ii) the set $\mathbb{R} \times \mathbb{R} \times \{ 0 \}$ is obviously the only supporting plane of $K$ that contains $p_{pr}$. Thus the normal cone is just the ray in direction $(0, 0, -1)$.

Assume $p_{pr} = (p_{pr}^1, 0, 0), p_{pr}^1 > 0$. Then there is some $\varepsilon > 0$ such that $\{(p_{pr}^1 + \varepsilon, 0, 0), (p_{pr}^1 - \varepsilon, 0, 0), (p_{pr}^1, \varepsilon, 0)\} \subset K$. Therefore $N_K(p_{pr}) \subset \{ 0 \} \times \mathbb{R}^+ \times \mathbb{R}$. For $\mathbb{R} \times \{ 0 \} \times \mathbb{R}$ and $\mathbb{R} \times \mathbb{R} \times \{ 0 \}$ are supporting planes of $K$ that contain $p_{pr}$, one must have $\{ 0 \} \times \mathbb{R} \times \mathbb{R} \subseteq N_K(p_{pr})$. Moreover, for $\lim_{z \to +\infty} \partial_2 \theta(p_{pr}^1, z) < \infty$ let $z = (z_1, z_2) \in \partial^+ \theta(p_{pr}^1, 0)$. One must have $z_1 = 0$ and $z_2 \in \partial^+ f(0)$ with auxiliary function $f : t \mapsto \partial \theta(p_{pr}^1, t)$. Then $(q \in \mathbb{R}^3 : \langle q - p_{pr}, (0, -z_2, 1) \rangle = 0$ is a supporting plane of $K$ and consequently $(0, -z_2, 1) \in N_K(p_{pr})$. Conversely, from $z_2 \not\in \partial^+ f(0)$ follows $(0, -z_2, 1) \not\in N_K(p_{pr})$. So

$$N_K(p_{pr}) = \{ 0 \} \times \mathbb{R}^+ \times \mathbb{R} \cup \{ (0, -\lambda \cdot z, \lambda) : z \in \partial^+ f(0), \lambda \in (0, +\infty) \}.$$ 

The auxiliary function $f$ is concave and by monotonicity of the super-differential we find $\partial^+ f(0) = [\lim_{z \to +\infty} \partial_2 \theta(p_{pr}^1, z), +\infty)$. With this characterization we arrive at the expression for $N_K(p_{pr})$ as given in (iii). The proof for the second axis is analogous.

For $p_{pr} = (0, 0, 0)$ we find $(\mathbb{R}^3)^3 \subset N_K(0) \subset \mathbb{R}^+ \times \mathbb{R}^+ \times \mathbb{R}$ with arguments analogous to those in case (iii). For every $z = (z_1, z_2) \in \partial^+ \theta(0)$ a supporting plane through 0 is given by $(q \in \mathbb{R}^3 : \langle q, (z_1, -z_2, 1) \rangle = 0$ and hence $(-z_1, -z_2, 1) \in N_K(0)$. Conversely, $z = (z_1, z_2) \not\in \partial^+ \theta(0)$ implies $(-z_1, -z_2, 1) \not\in N_K(0)$. With this, one obtains the expression for $N_K(0)$ given in (iv).

Finally, we consider $p_{pr} = (p_{pr}^1, p_{pr}^2, \theta(p_{pr}^1, p_{pr}^2))$ with $(p_{pr}^1, p_{pr}^2) \in (0, +\infty)^2$. In a neighbourhood of $p_{pr}$, $K$ is the subgraph of a concave, differentiable function. The unique supporting plane of $K$ through $p_{pr}$ is given by $(q \in \mathbb{R}^3 : \langle q - p_{pr}, (-\partial_1 \theta(p_{pr}^1, p_{pr}^2), -\partial_2 \theta(p_{pr}^1, p_{pr}^2), 1) \rangle = 0) \text{ and } (-\partial_1 \theta(p_{pr}^1, p_{pr}^2), -\partial_2 \theta(p_{pr}^1, p_{pr}^2), 1) \text{ is the unique associated outer normal as stated in (v).}$

Using Lemma 4.4 one can devise an algorithm for the projection onto $K$. For $p = (p_1, p_2, p_3) \in \mathbb{R}^3$ the projection $p_{pr} = \text{proj}_K(p)$ can be determined as follows:

```
function ProjectK(p1,p2,p3)
    if 0 ≤ p3 ≤ θ(p1,p2) return (p1,p2,p3)
    if p3 ≤ 0 return (max{p1,0}, max{p2,0},0)
    if (p1 > 0) ∧ (p2 ≤ 0) then
        if ¬p2/p3 ≥ lim_{z→p1} \partial_2 \theta(p1,p2) return (p1,0,0)
    end if
    if (p1 ≤ 0) ∧ (p2 > 0) then
        if ¬p1/p3 ≥ lim_{z→p1} \partial_1 \theta(p1,p2) return (0,p2,0)
    end if
    if (p1 ≤ 0) ∧ (p2 ≤ 0) then
        if (¬p1/p3,¬p2/p3) ∈ \partial^+ θ(0) return (0,0,0)
    end if
    return ProjectKTop(p1,p2,p3)
end function
```

The function ProjectKTop(p1,p2,p3) in the above algorithm corresponds to case (v) of Lemma 4.4, where $p_{pr}$ lies on the ‘upper surface’ of $K$, defined by the graph surface of $\theta$. It will be described in more detail below. In the following we will occasionally use the curve $c : (0, \infty) → \mathbb{R}$. 

20
Since that, we get $\theta$ is unique, this must be the unique root of $q$. Since $\theta$ is 1-homogeneous, any $p^\theta$ of the form $(p_1^\theta, p_2^\theta, \theta(p_1^\theta, p_2^\theta))$, $(p_1^\theta, p_2^\theta) \in (0, +\infty)^2$, can be written as $p^\theta = \tau \cdot \theta(q)$ for unique $q \in (0, +\infty)$ and $\tau \in (0, +\infty)$. In explicit, $q = p_1^\theta/p_2^\theta$ and $\tau = (p_1^\theta \cdot p_2^\theta)^{1/2}$. Now, $n(q)$ is orthogonal on the graph of $\theta$ and outward pointing. Hence, $p$ lies in the plane spanned by $\theta(q)$ and $n(q)$. This is equivalent to $\langle p, \theta(q) \times n(q) \rangle = 0$. Since $p^\theta$ is unique, this must be the unique root of $q \mapsto \langle p, \theta(q) \times n(q) \rangle$. Once $q$ is determined, we know the ray on which $p^\theta$ lies. To find $\tau$, one must solve the remaining one-dimensional projection onto the ray. Consequently, $\tau$ is the unique minimizer of $\tau \mapsto \frac{1}{2} \| p - \tau \cdot \theta(q) \|^2$, which concludes the proof. □

For case (iv) of Lemma 4.4 we need to characterize the super-differential of $\theta$ at the origin.

**Lemma 4.6.** The super-differential of $\theta$ at the origin is given by

$$\partial^+ \theta(0) = \left\{ (\nabla \theta(q^{-1/2}, q^{1/2}) : q \in (0, \infty) \right\} + (\mathbb{R}^+_0)^2.$$ 

**Proof.** Due to the 1-homogeneity of $\theta$

$$\langle \nabla \theta(\lambda p), \lambda r \rangle = \lim_{\epsilon \to 0} \frac{\theta(\lambda(p + \epsilon r)) - \theta(\lambda p)}{\epsilon} = \lambda \lim_{\epsilon \to 0} \frac{\theta(p + \epsilon r) - \theta(p)}{\epsilon} = \lambda \langle \nabla \theta(p), r \rangle$$

for $p \in (0, +\infty)^2$, $\lambda > 0$, and all $r \in \mathbb{R}^2$, which leads to $\nabla \theta(\lambda p) = \nabla \theta(p)$ for $p \in (0, +\infty)^2$ and $\lambda > 0$. Thus, for the curve $c : (0, \infty) \to \mathbb{R}^2 ; q \mapsto (q^{-1/2}, q^{1/2})$ the set of tangent planes at $(c(q), \theta(c(q)))$ spanned by $(\nabla \theta(c(q)), 1)$ and $(c(s), \theta(c(q)))$ for $q \in (0, \infty)$ is already the complete set of affine tangent planes to the graph of $\theta$ over $(0, \infty)^2$. Thus, by continuity of $\theta$ on $[0, \infty)^2$ we get $\theta(0) + \langle r, p \rangle \geq \theta(p)$ for $r \in \nabla \theta(\epsilon) : q \in (0, \infty)$. From this we deduce that $\partial^+ \theta(0) \supset \{ \nabla \theta(c(q)) : q \in (0, \infty) \} + (\mathbb{R}^+_0)^2$. Since $\partial^+ \theta(0)$ is a closed set [BC11, Prop. 16.3], this implies

$$\partial^+ \theta(0) \supset \left\{ (\nabla \theta(c(s)) : q \in (0, \infty) \right\} + (\mathbb{R}^+_0)^2.$$ 

Furthermore, for any $w \in \mathbb{R}^2 \setminus \{0\}$ with $w_1, w_2 \leq 0$ there exists a $p^\theta$ with $\theta(0) + \langle r + w, p^\theta \rangle < \theta(p^\theta)$. Since $\theta(z) = 0$ for $z \in \{(0, 0) \times \mathbb{R}^+_0 \} \cup (\mathbb{R}^+_0 \times \{0\})$ and $\theta(z) = -\infty$ outside $[0, \infty)^2$ we finally obtain that $\theta(0) + \langle r, p \rangle \geq \theta(p)$ if and only if $r \in \{ \nabla \theta(c(q)) : q \in (0, \infty) \} + (\mathbb{R}^+_0)^2$, which proves the claim. □

**Logarithmic Mean.** Now, we turn to the specific case when $\theta = \theta_{\log}$ is the logarithmic mean (4). For $s > 0 \lim_{t \to 0} \delta_\theta(t, s) = \lim_{\epsilon \to 0} \epsilon \delta_\theta(s, t) = +\infty$. That is, $N_K(s, 0, 0) = \{0\} \times \mathbb{R}^+_0 \times \mathbb{R}^2_-$ and analogous $N_K(0, s, 0) = \mathbb{R}^+_0 \times \{0\} \times \mathbb{R}^-_0$. Consequently, the algorithm simplifies as follows:

```cpp
function ProjectK(p1, p2, p3)
    if 0 ≤ p3 ≤ \theta(p1, p2) return (p1, p2, p3)
    if p3 ≤ 0 return (max{p1}, max{p2, 0}, 0)
    if (p1 ≤ 0) ∧ (p2 ≤ 0) ∧ (−p1/p2, −p2/p1) ∈ \partial^+ \theta(0) return (0, 0, 0)
    return ProjectKTop(p1, p2, p3)
end function
```

21
The inclusion in \( \partial^+ \theta(0) \) can be tested as follows.

**Lemma 4.7.** Let \( z = (z_1, z_2) \in \mathbb{R}^2 \). If \( \min\{z_1, z_2\} \leq 0 \) then \( z \notin \partial^+ \theta(0) \). Otherwise, there is a unique \( q_1 \in (0, +\infty) \) such that \( \tilde{c}_1 \theta(q_1^{-1/2}, q_1^{1/2}) = z_1 \) and then \( z \in \partial^+ \theta(0) \) if and only if \( z_2 \geq \tilde{c}_2 \theta(q_1^{-1/2}, q_1^{1/2}) \).

**Proof.** Note that for the logarithmic mean \( \partial^+ \theta(0) \subset (0, +\infty)^2 \) and therefore \( z \notin \partial^+ \theta(0) \) if \( \min\{z_1, z_2\} \leq 0 \). One finds that

\[
\tilde{c}_1 \theta(q_1^{-1/2}, q_1^{1/2}) = \frac{q - 1 - \log(q)}{\log^2(q)}
\]

is monotone increasing with \( \tilde{c}_1 \theta(q_1^{-1/2}, q_1^{1/2}) \to 0 \) as \( q \to 0 \) and \( \tilde{c}_1 \theta(q_1^{-1/2}, q_1^{1/2}) \to +\infty \) as \( q \to +\infty \). Indeed, for \( \beta(q) = \tilde{c}_1 \theta(q_1^{-1/2}, q_1^{1/2}) \) with \( \beta(1) := \frac{1}{2} \) we obtain a continuous extension on \((0, \infty)\). Furthermore, we consider \( \beta'(q) = \frac{2(1 - q + \log(q)(1 + q))}{q \log(q)} \) with continuous extension \( \frac{1}{6} \) for \( q = 1 \) and verify that \( 2(1 - q) + \log(q)(1 + q) \) is negative for \( q < 1 \) and positive for \( q > 1 \). This implies that \( \beta'(q) > 0 \). Furthermore, by symmetry we obtain that \( \tilde{c}_2 \theta(q_2^{-1/2}, q_2^{1/2}) \) is monotone decreasing with \( \tilde{c}_2 \theta(q_2^{-1/2}, q_2^{1/2}) \to +\infty \) as \( q \to 0 \) and \( \tilde{c}_2 \theta(q_2^{-1/2}, q_2^{1/2}) \to 0 \) as \( q \to +\infty \). By Lemma 4.6

\[
\partial^+ \theta(0) = \{ \forall \theta(q_1^{-1/2}, q_1^{1/2}) : q \in (0, +\infty) \} + (\mathbb{R}_+)^2.
\]

Thus, for every \( z \in (0, +\infty)^2 \) there is a unique \( q_1 \in (0, +\infty) \) such that \( \tilde{c}_1 \theta(q_1^{-1/2}, q_1^{1/2}) = z_1 \) and \( z_1 \geq \tilde{c}_1 \theta(q_1^{-1/2}, q_1^{1/2}) \) if and only if \( q \leq q_1 \). Furthermore, there is a unique \( q_2 \in (0, +\infty) \) such that \( \tilde{c}_2 \theta(q_2^{-1/2}, q_2^{1/2}) = z_2 \) and \( z_2 \geq \tilde{c}_2 \theta(q_2^{-1/2}, q_2^{1/2}) \) if and only if \( q \geq q_2 \). Hence, \( z \in \partial^+ \theta(0) \) if and only if \( q \leq q_1 \) and \( q \geq q_2 \), which is equivalent to \( z_2 \leq \tilde{c}_2 \theta(q_1^{-1/2}, q_1^{1/2}) \).

**Remark 4.8 (Comments on Numerical Implementation).** The sought-after \( q \) in Lemma 4.7 can be determined with a one-dimensional Newton iteration. The function \( q \mapsto \tilde{c}_1 \theta(q_1^{-1/2}, q_1^{1/2}) \) becomes increasingly steep as \( q \to 0 \) which leads to increasingly unstable Newton iterations as \( z_1 \) approaches 0. On \( q \in [1, +\infty) \) the function is rather flat and easy to invert numerically. To avoid these numerical problems, note that the roles of \( z_1 \) and \( z_2 \) in Lemma 4.7 can easily be swapped which corresponds to the transformation \( q \leftrightarrow q^{-1} \). Moreover, for \( \max\{z_1, z_2\} < \frac{1}{2} \) one has \( z \notin \partial^+ \theta(0) \). With this rule and by swapping the values of \( z_1 \) and \( z_2 \) if \( z_1 \leq z_2 \) one can always remain in the regime \( q \in [1, +\infty) \). Additionally, we recommend to replace the function \( \theta(s, t) \) and its derivatives by a local Taylor expansion near the numerically unstable diagonal \( s = t \).

**Geometric Mean.** Furthermore, let us consider the case where \( \theta = \theta_{\text{geo}} \) is the geometric mean (4). For \( s > 0 \) we again find \( \lim_{r \to 0} \tilde{c}_1 \theta(t, s) = \lim_{r \to 0} \tilde{c}_2 \theta(s, t) = +\infty \) and consequently the same simplification of the algorithm applies as in the case of the logarithmic mean. For the test of the inclusion \( z = (z_1, z_2) \in \partial^+ \theta(0) \), we argue as in the proof of Lemma 4.7. The functions \( \tilde{c}_1 \theta(q_1^{-1/2}, q_1^{1/2}) = \frac{1}{2} q^{-1/2} \) and \( \tilde{c}_2 \theta(q_2^{-1/2}, q_2^{1/2}) = \frac{1}{2} q^{-1/2} \) have the same monotonicity properties as for the logarithmic mean. Therefore, if \( \min\{z_1, z_2\} \leq 0 \) then \( z \notin \partial^+ \theta(0) \). Otherwise, \( q_1 = 4 z_1^2 \) and thus the condition \( \tilde{c}_2 \theta(q_1^{-1/2}, q_1^{1/2}) \leq z_2 \) is equivalent to \( z_1 \cdot z_2 \geq \frac{1}{4} \). To summarize, we have obtained

\[
\partial^+ \theta(0) = \{ z \in \mathbb{R}^2 : z_1 \cdot z_2 \geq \frac{1}{4} \land \min\{z_1, z_2\} > 0 \}
\]
4.5 Proximal Mapping of $I^*_{\mathcal{F}_\pm}$

Note that $I_{\mathcal{F}_\pm}$ is a 1-homogeneous function. Hence, $I^*_{\mathcal{F}_\pm}$ will once again be an indicator function and $\text{prox}_{I^*_{\mathcal{F}_\pm}}$ a projection. Consequently, the proximal mapping is independent of the step size $\sigma$, i.e. $\text{prox}_{\sigma I^*_{\mathcal{F}_\pm}} = \text{prox}_{I^*_{\mathcal{F}_\pm}}$. To compute $\text{prox}_{I^*_{\mathcal{F}_\pm}}$ we use Moreau’s decomposition [BC11, Thm. 14.3] that implies

$$\text{prox}_{I^*_{\mathcal{F}_\pm}} = \text{id} - \text{prox}_{I_{\mathcal{F}_\pm}} = \text{id} - \text{proj}_{I_{\mathcal{F}_\pm}}$$

where id is the identity map on $V_{n,h}^0 \times (V_{c,h}^0)^2$. To compute $\text{proj}_{I_{\mathcal{F}_\pm}}(\rho, \rho^-, \rho^+)$ for a point $(\rho, \rho^-, \rho^+) \in V_{n,h}^0 \times (V_{c,h}^0)^2$ one has to find the minimizer $(\rho^{pr}, \rho^{-pr}, \rho^{+pr}) \in I_{\mathcal{F}_\pm}$ of

$$\sum_{i=0}^{N-1} |\rho^{pr}(t_i, \cdot) - \rho(t_i, \cdot)|_2^2 + \|\rho^{-pr}(t_i, \cdot) - \rho^-(t_i, \cdot, \cdot)\|_2^2 + \|\rho^{+pr}(t_i, \cdot, \cdot) - \rho^+(t_i, \cdot, \cdot)\|_2^2.$$

Recall that for any $\rho^{pr} \in V_{n,h}^0$ there is precisely one pair $(\rho^{-pr}, \rho^{+pr}) \in (V_{c,h}^0)^2$ such that $(\rho^{pr}, \rho^{-pr}, \rho^{+pr}) \in I_{\mathcal{F}_\pm}$, see (23). Therefore, one has to find $\rho^{pr} \in V_{n,h}^0$ which minimizes

$$\sum_{i=0}^{N-1} \sum_{x \in X} |\rho^{pr}(t_i, x) - \rho(t_i, x)|^2 \pi(x) + \frac{1}{2} \sum_{(x,y) \in \mathcal{X}^2} |\rho^{pr}(t_i, x) - \rho^-(t_i, x, y)|^2 Q(x,y) \pi(x) + \frac{1}{2} \sum_{(x,y) \in \mathcal{X}^2} |\rho^{pr}(t_i, y) - \rho^+(t_i, x, y)|^2 Q(x,y) \pi(x).$$

The optimality condition in $\rho^{pr}$ in combination with the reversibility $Q(x,y)\pi(x) = Q(y,x)\pi(y)$ yields for $i = 0, \ldots, N-1, x \in X$

$$\rho^{pr}(t_i, x) = \frac{1}{2} \left( \rho(t_i, x) + \frac{1}{2} \sum_{y \in X} (\rho^-(t_i, x, y) + \rho^+(t_i, y, x))Q(x,y) \right)$$

and subsequently $\rho^{-pr}(t_i, x, y) = \rho^{pr}(t_i, x), \rho^{+pr}(t_i, x, y) = \rho^{pr}(t_i, y)$ for $(x, y) \in X \times X$. Finally, for $(\rho^{pr}, \rho^{-pr}, \rho^{+pr}) = \text{proj}_{I_{\mathcal{F}_\pm}}(\rho, \rho^-, \rho^+)$ using (33) one gets $\text{prox}_{I^*_{\mathcal{F}_\pm}}(\rho, \rho^-, \rho^+) = (\rho, \rho^-, \rho^+) - (\rho^{pr}, \rho^{-pr}, \rho^{+pr})$.

4.6 Proximal Mapping of $I^*_{\mathcal{F}_{\text{avg}}}$

Once more, we use Moreau’s decomposition, (33), to compute the proximal mapping of $I^*_{\mathcal{F}_{\text{avg}}}$ via the projection onto $I_{\mathcal{F}_{\text{avg}}}$. Note that the original problem (26) does not change if we add the constraint $\rho_h(t_{0,h}, \cdot) = \rho_A$ and $\rho_h(t_{n,h}, \cdot) = \rho_B$ to the set $I_{\mathcal{F}_{\text{avg}}}$. That is, we consider the projection onto the set

$$I_{\mathcal{F}_{\text{avg}}} = \{(\rho_h, \rho_h) \in I_{\mathcal{F}_{\text{avg}}}: \rho_h(t_{0,h}, \cdot) = \rho_A, \rho_h(t_{n,h}, \cdot) = \rho_B\}.$$

To compute the projection we have to solve

$$\arg\min_{(\rho_h^{pr}, \rho_h^{-pr}) \in I_{\mathcal{F}_{\text{avg}}}} \frac{1}{2} \sum_{i=0}^{N} \sum_{x \in X} |\rho_h^{pr}(t_i, x) - \rho_h(t_i, x)|_2^2 \pi(x) + \frac{1}{2} \sum_{i=0}^{N-1} \sum_{x \in X} |\rho_h^{-pr}(t_i, x) - \rho_h(t_i, x)|_2^2 \pi(x).$$
Thus, we introduce a Lagrange multiplier $\lambda_h \in \mathbb{V}_h^0$ and define the corresponding Lagrangian

$$L(p_h^{pr}, p_h^{pr}, \lambda_h) = \frac{1}{2} \sum_{i=0}^{N} \sum_{x \in \mathcal{X}} |p_h^{pr}(t,x) - \rho_h(t,x)|^2 \pi(x) + \frac{1}{2} \sum_{i=0}^{N-1} \sum_{x \in \mathcal{X}} |p_h^{pr}(t,x) - \rho_h(t,x)|^2 \pi(x)$$

$$- \sum_{i=0}^{N-1} \sum_{x \in \mathcal{X}} \lambda_h(t_i,x) \left( \text{avg}_h p_h^{pr}(t_i,x) - p_h^{pr}(t_i,x) \right) \pi(x).$$

We know directly from the added boundary constraints that

$$p_h^{pr}(t_0,x) = \rho_A, \quad p_h^{pr}(t_N,x) = \rho_B.$$ 

The optimality condition in $p_h^{pr}$ for all $x \in \mathcal{X}$ and for interior time steps $i = 1, \ldots, N - 1$ reads as

$$p_h^{pr}(t_i,x) = \rho_h(t_i,x) + \frac{1}{2}(\lambda_h(t_{i-1},x) + \lambda_h(t_i,x)).$$

(34)

Further, the optimality condition in $p_h^{pr}$ implies that on each interval

$$p_h^{pr}(t_i,x) = \rho_h(t_i,x) - \lambda_h(t_i,x).$$

(35)

Combining both with the constraint $\text{avg}_h p_h^{pr}(t_i,x) = p_h^{pr}(t_i,x)$, we obtain

$$\rho_h(t_i,x) - \lambda_h(t_i,x) = p_h^{pr}(t_i,x) = \text{avg}_h p_h^{pr}(t_i,x)$$

$$= \text{avg}_h \rho_h(t_i,x) + \frac{1}{4}(\lambda_h(t_{i-1},x) + 2\lambda_h(t_i,x) + \lambda_h(t_{i+1},x))$$

for all interior elements $l_i$ with $i = 1, \ldots, N - 2$ and for all $x \in \mathcal{X}$. Analogously, using the boundary conditions we get

$$\rho_h(t_0,x) - \lambda_h(t_0,x) = \frac{1}{2}(\rho_A(x) + \rho_h(t_1,x)) + \frac{1}{2}(\lambda_h(t_0,x) + \lambda_h(t_1,x))$$

$$\rho_h(t_{N-1},x) - \lambda_h(t_{N-1},x) = \frac{1}{2}(\rho_A(x) + \rho_h(t_{N-1},x)) + \frac{1}{4}(\lambda_h(t_{N-2},x) + \lambda_h(t_{N-1},x)).$$

Thus, for each $x \in \mathcal{X}$ the Lagrange multiplier $\lambda_h$ satisfies the linear system of equations

$$\frac{1}{4}(5\lambda_h(t_0,x) + \lambda_h(t_1,x)) = \rho_h(t_0,x) - \frac{1}{2}(\rho_A(x) + \rho_h(t_1,x))$$

$$\frac{1}{4}(\lambda_h(t_{i-1},x) + 6\lambda_h(t_i,x) + \lambda_h(t_{i+1},x)) = \rho_h(t_i,x) - \frac{1}{2}(\rho_h(t_{i-1},x) + \rho_h(t_{i+1},x)) \quad \forall i = 1, \ldots, N - 2$$

$$\frac{1}{4}(\lambda_h(t_{N-2},x) + 5\lambda_h(t_{N-1},x)) = \rho_h(t_{N-1},x) - \frac{1}{2}(\rho_A(x) + \rho_h(t_{N-1},x))$$

This system is solvable, since the corresponding matrix with diagonal $(5, 6, \ldots, 6, 5)$ and off-diagonal 1 is strictly diagonal dominant. Then, given the Lagrange multiplier $\lambda_h$, the solution of the projection problem is given by (34) and (35). Finally, the proximal map of $I_{F_w}$ can be computed by Moreau’s identity, (33). Thus, to compute the proximal mapping of $I_{F_w}$ one must solve a sparse system in time for each graph node separately. Since the involved matrix is constant, it can be pre-factored.

4.7 Proximal Mapping of $I_{F_w}$

The proximal map of $I_{F_w}$ is given by the projection

$$\text{proj}_{I_{F_w}}(\rho_h, q_h) = \arg \min_{(\rho_h^{pr}, q_h^{pr}) \in \mathbb{V}_h^0 \times \mathbb{V}_h^0} \left\{ \frac{1}{2} \sum_{i=0}^{N-1} \sum_{x \in \mathcal{X}} \left( (\rho_h - \rho_h^{pr})^2 + |q_h - q_h^{pr}|^2 \right) Q(x,y) \pi(x) \right\}$$

$$= \frac{1}{2} (\rho_h + q_h, \rho_h + q_h).$$
5 Numerical Results

In what follows we compare the numerical solution based on our discretization with the explicitly known solution for a simple model with just two nodes. Furthermore, we apply our method to a set of characteristic test cases to study the qualitative and quantitative behaviour of the discrete transportation distance.

Comparison with the exact solution for the 2-node case. Consider a two point graph $X = \{a, b\}$ with Markov chain and stationary distribution

$$Q = \begin{pmatrix} 0 & p \\ q & 0 \end{pmatrix}, \quad \pi = \begin{pmatrix} \frac{q}{p+q} \\ \frac{p}{p+q} \end{pmatrix},$$

where $p, q \in (0, 1]$. For this case, Maas [Maa11] constructed an explicit solution for the geodesic from $\rho_A = \left(\frac{p+q}{q}, 0\right)$ to $\rho_B = \left(0, \frac{p+q}{p}\right)$. Note that every probability measure on $X$ can be described by a single parameter $r \in [-1, 1]$ via

$$\rho(r) = (\rho_a(r), \rho_b(r)) = \left(\frac{p + q 1 - r}{q}, \frac{p + q 1 + r}{p}\right).$$

Especially, we have $\rho_A = \rho(-1)$ and $\rho_B = \rho(1)$. Using this representation, Maas showed that for $-1 \leq \alpha \leq \beta \leq 1$ the optimal transport distance is given by

$$W(\rho(\alpha), \rho(\beta)) = \frac{1}{2} \sqrt{\frac{1}{q} + \frac{1}{q} \int_{\alpha}^{\beta} \frac{1}{\sqrt{\theta(\rho_a(r), \rho_b(r))}} \, dr}$$

and the optimal transport geodesic from $\rho(\alpha)$ to $\rho(\beta)$ is given by $\rho(\gamma(t))$ for $t \in [0, 1]$, where $\gamma$ satisfies the differential equation

$$\gamma'(t) = 2(\beta - \alpha)W(\rho(\alpha), \rho(\beta)) \sqrt{\frac{pq}{p+q} \Theta(\gamma_a(t)), \rho_b(\gamma(t))}. \tag{37}$$

For the special case, where $\theta$ is the logarithmic mean $\theta_{\log}$ and $p = q$, one obtains that $\theta_{\log}(\rho_a(r), \rho_b(r)) = \frac{r}{\arctanh(r)}$, and consequently the discrete transport distance is given by

$$W(\rho(\alpha), \rho(\beta)) = \frac{1}{\sqrt{pq}} \int_{\alpha}^{\beta} \sqrt{\frac{1}{\theta_{\log}(r)}} \, dr.$$ Furthermore, the optimal transport geodesic from $\rho(\alpha)$ to $\rho(\beta)$ is given by $\rho(\gamma(t))$ for $t \in [0, 1]$, where $\gamma$ satisfies the differential equation $\gamma'(t) = \sqrt{2pq(\beta - \alpha)}W(\rho(\alpha), \rho(\beta)) \sqrt{\frac{\gamma(t)}{\arctanh(\gamma(t))}}$. For this two point graph we numerically compute the optimal transport geodesic. This allows us to evaluate directly the distance $W$, which we can compare with a numerical quadrature of (36). Using the approximation of $W$, we use an explicit Euler scheme to compute the solution $\rho_{\text{ODE}}^t$ of the ODE (37). For the case $p = q = 1$ we compare our numerical solution to the Euler approximation for the ODE for $N = 2000$ in Fig. 1.

Geodesics on some selected graphs. Let us consider four different graphs whose nodes and edges form a triangle, the $3 \times 3$ lattice, a cube, and a hypercube, respectively. Figure 2 depicts these graphs with labeled nodes and edges. In all cases, we set for each node $x$ with $m$ outgoing edges $\pi(x) = \frac{m}{m^2}$ and $Q(x, y) = \frac{1}{\pi(x) \pi(y)}$. Figure 3 shows numerically computed geodesic paths. The underlying time step size is $h = 1$. The solution $(\rho, m)$ is displayed at intermediate time
Figure 1: The mass distribution at \( b \) is plotted over time \( t \in [0,1] \). Left: Numerical solution for a 2-point graph \( X = \{a,b\} \) for the logarithmic (red) and geometric (green). The black line represents the diagonal, which is the solution in the case of the (non admissible) arithmetic averaging. Right: Difference of the numerical solution for the logarithmic (red) and geometric (green) mean with the Euler scheme solution \( \rho_{b,\text{ODE}} \) for the logarithmic mean.

Figure 2: Labeling of nodes and edges for four different graphs: a triangle, the 3x3 lattice, a cube, and a hypercube.
with uniform mesh size \(1\) by \(Q\).

Along this line we perform the following numerical experiments for the classical \(L^2\)-Wasserstein distance on \(T^d\). In fact, the optimal transport with respect to the classical \(L^2\)-Wasserstein distance between two point masses is a point mass travelling along the connecting straight line. Concerning the expected concentration of the transport along this line we perform the following numerical experiments for \(d = 1, 2\). We first consider for \(d = 1\) the unit interval \(I = [0, 1]\) and a sequence of space discretizations \(X_M = \{x_0, \ldots, x_M\}\) with uniform mesh size \(\frac{1}{M}\) with \(M \in \mathbb{N}\). The corresponding Markov kernel \(Q_M\) for \(X_M\) is defined by \(Q_M(x_i, x_{i+1}) = Q_M(x_i, x_{i-1}) = \frac{1}{2}\) for \(i = 1, \ldots, x_M-1\) and \(Q_M(x_0, x_1) = 1 = Q_M(x_M, x_M-1)\). The continuous \(L^2\)-Wasserstein geodesic connecting \(\rho_A = \delta_0\) and \(\rho_B = \delta_1\) is given by the transport of the Dirac measure with constant speed:

\[
\rho(t, x) = \delta_t(x).
\]

In Figure 6 we plot the density distribution of the discrete optimal transport geodesic at time \(t = \frac{1}{M}\) for different grid sizes \(\frac{1}{M}\). One observes the onset of mass concentration in space at that time at the location \(x = \frac{1}{2}\) for increasing \(M\). For \(d = 2\) we consider a square lattice of uniform grid size \(\frac{1}{M}\) with \(M \in \mathbb{N}\) and nodes \(X_M = \{(i/M, j/M) : i, j \in \{0, \ldots, M\}\}\). The weights of the Markov kernel \(Q\) are proportional to the number of adjacent edges. Now, we investigate a discrete geodesic connecting the Dirac masses \(\delta_{(0,0)}\) and \(\delta_{(1,1)}\). One expects that for increasing \(M\) mass on bands parallel to the space diagonal will decrease. In Figure 7 we plot for decreasing mesh size \(\frac{1}{M}\) the in time accumulated density values along the diagonal and the off-diagonals bands of nodes. More precisely, we define the bands of nodes \(\delta_{(i)} \subset X_M \times X_M : x_2 = x_1 + \frac{i}{M}\) \((i = 0\) being the diagonal) and compare the values \(\int_0^1 \sum_{x \in \delta_{(i)}} \rho(t, x)\pi(x)\ dt\).

**Experimental results related to the Gromov-Hausdorff convergence for simple graphs.** In [GM13] it was shown that for the \(d\)-dimensional torus \(T^d\) the discrete transportation distance \('W'\) on a discretized torus \(T^d_M\) with uniform mesh size \(\frac{1}{M}\) converges in the Gromov-Hausdorff metric to the classical \(L^2\)-Wasserstein distance on \(T^d\). Finally, in Figure 5 we depict an example of graph with four nodes, which shows that the sign of the momentum variable on a fixed edge may change along a geodesic path.

**Discrete geodesics on an internet network of Europe.** In Figure 8 we apply the investigated optimal transport model to a coarse scale internet network of Europe and show experimental results with masses (data packages) transported from Dublin, Lisbon, and Madrid to Athens,
Figure 3: Numerically computed geodesics on a triangle, a square lattice and a cube for prescribed boundary conditions at time 0 and 1. Note in particular the symmetry under time reversal and the spreading of mass at intermediate times (equidistribution at $t = \frac{1}{2}$ for the cube).
Figure 4: Top: Numerically computed geodesic on a hypercube. Bottom: Distribution of mass and momentum, note again the symmetry under time reversal and the spreading of mass, with equidistribution at time $t = \frac{1}{2}$.

Figure 5: Numerically computed geodesic on a graph with four nodes. Note that the sign of $m$ for edge 2 changes (cf. $t = \frac{1}{5}$ and $t = \frac{4}{5}$).
Figure 6: Linearly interpolated densities for the $\mathcal{W}$ geodesic on a one dimensional chain graph between a Dirac mass at the beginning and the end, at $t = 0.5$ with $M = 2$ (blue), 4 (red), 8 (green), 16 (orange), 32 (yellow), and 64 (black).

Figure 7: Geodesics in the distance $\mathcal{W}$ on a two dimensional grid graph between Dirac masses at diagonally opposite ends. We show accumulated densities along the diagonal and the off-diagonals (see text for details). From left to right: $M = 4, 8, 16, 32$. The width of the bars is scaled with the number of lines.
Stockholm, and Kiev. Also here, we set for each node \( x \) with \( m \) outgoing edges \( \pi(x) = \frac{m}{|E|} \) and \( Q(x, y) = \frac{1}{\pi(x)\pi(y)} \), with \(|E|\) the total number of (directed) edges.

6 Simulation of the gradient flow of the entropy

The entropy functional on \( \mathcal{P}(X) \) is given by

\[
\mathcal{H}(\rho) = \sum_{x \in X} \rho(x) \log(\rho(x)) \pi(x),
\]

with the usual convention \( '0 \log 0 = 0' \). Maas [Maa11] proved that for the logarithmic mean \( \theta_{\log}(\cdot, \cdot) \) and \( \rho \in \mathcal{P}(X) \) the heat flow \( t \mapsto e^{\tau \Delta} \rho \) is a gradient flow trajectory for the entropy \( \mathcal{H}(\rho) \) with respect to the discrete transportation distance \( \mathcal{W} \). In [EM14] it was shown that a similar result holds true for the Renyi entropy

\[
\mathcal{H}_m(\rho) = \frac{1}{m-1} \sum_{x \in X} \rho(x)^m \pi(x).
\]

In fact, for \( m = \frac{1}{2} \) and the gradient flow of \( \mathcal{H}_m \) with respect to the metric \( \mathcal{W} \) constructed with \( \theta \) being the geometric mean \( \theta_{\text{geom}}(\cdot, \cdot) \) is given by the Fokker-Planck equation \( \partial_t \rho = \Delta_X \rho^m \).

To verify this property numerically, we consider a line of five points with stationary distribution \( \pi = \frac{1}{5} p_1, p_2, p_2, p_2, p_1 \), Markov kernel \( Q(x, y) = \frac{1}{10} \pi(x) \) for \( x, y \) adjacent, and initial mass \( \rho = \frac{1}{5} (1, 1, 5, 1, 1) \). Following [JKO98, AGS08], for an initial density \( \rho_0 \in \mathcal{P}(X) \) and a time step size \( \tau > 0 \) an implicit time-discrete gradient flow scheme for \( \mathcal{H} \) can be defined by

\[
\rho_{k+1} = \arg\min_{\rho_0} \frac{1}{2} \mathcal{W}_h(\rho_k, \rho_0)^2 + \tau \cdot \mathcal{H}(\rho_0)
\]

(38)

with an inner time step size \( h \) appearing in the discretization \( \mathcal{W}_h \) of \( \mathcal{W} \). To minimize this functional numerically, we simultaneously carry out the external optimization over \( \rho \) and the internal optimization within \( \mathcal{W}_h \). To this end, we define a discrete continuity equation with one free endpoint. For initial datum \( \rho_A \in \mathcal{P}(X) \) let

\[
CE_h(\rho_A) = \left\{ (\rho_h, m_h, \rho_B) \in V_{n,h}^1 \times V_{v,h}^0 \times \mathbb{R}^X : (\rho_h, m_h) \in CE_h(\rho_A, \rho_B) \right\}.
\]
Analogous to (26), problem (38) can be written as

\[
\min \{ \mathcal{F}(\rho_h, m_h, \delta_h, \rho_h^+, \rho_h^-, \rho_h, q_h, \rho_B) + \mathcal{G}(\rho_h, m_h, \delta_h, \rho_h^+, \rho_h, q_h, \rho_B) : (\rho_h, m_h, \delta_h, \rho_h^+, \rho_h^-, \rho_h, q_h, \rho_B) \in V^n \times V^n \times \mathbb{R}^3 \}
\]

with

\[
\mathcal{F}(\rho_h, m_h, \delta_h, \rho_h^+, \rho_h^-, \rho_h, q_h, \rho_B) := \tilde{\mathcal{A}}(\delta_h, m_h) + \mathcal{I}_{\mathcal{F}_2}(q_h, \rho_h^-) + \mathcal{I}_{\mathcal{F}_3}(\rho_h, \rho_h) + 2 \tau \cdot \mathcal{H}(\rho_B),
\]

\[
\mathcal{G}(\rho_h, m_h, \delta_h, \rho_h^+, \rho_h^-, \rho_h, q_h, \rho_B) := \mathcal{I}_{\mathcal{CE}_h}(\rho_h, m_h, \rho_B) + \mathcal{I}_{\mathcal{K}}(\rho_h^+, \rho_h^-) + \mathcal{I}_{\mathcal{J}}(\rho_h, q_h, \rho_B).
\]

Again, this is amenable for algorithm (28). We extend the space \( H \) by a factor \( \mathbb{R}^3 \) and adapt the scalar product on \( H(27) \) adding the term \( h \langle \rho_{B1}(\cdot), \rho_{B2}(\cdot) \rangle \) with respect or the additional variable \( \rho_B \). The proximal step of \( \mathcal{F}^* \) then entails an additional proximal step of \( (2 \tau \cdot \mathcal{H})^* \) with respect to \( h \| \cdot \|_\tau \) and in the proximal step of \( \mathcal{G} \) the projection onto \( \mathcal{C}E_h(\rho_A, \rho_B) \) is replaced by a projection onto \( \mathcal{C}E_h(\rho_B) \). Next, we detail these modifications.

Let us recall that the proximal mapping of \( (\gamma \cdot \mathcal{H})^* \) and \( \gamma \cdot \mathcal{H} \) are linked by Moreau’s decomposition, cf. (33). The computation of the the proximal mapping for \( \gamma \cdot \mathcal{H} \) decouples in space and the resulting one dimensional problem can be solved via Newton’s method. This decoupling is possible since we do not enforce the constraint \( \rho_B \in \mathcal{P}(X) \) in the formulation of \( \mathcal{H} \) but enforce it via the discrete continuity equation constraint.

To implement the projection

\[
\text{proj}_{\mathcal{C}E_h(\rho_A)}(\rho, m, \rho_B) = \arg \min_{(\rho', m', \rho_B') \in \mathcal{C}E_h(\rho_A)} \frac{h}{2} \sum_{i=0}^{N} \| \rho_h'(t_i, \cdot) - \rho_h(t_i, \cdot) \|_{L^2}^2 + \frac{h}{2} \sum_{i=0}^{N-1} \| m_h'(t_i, \cdot) - m_h(t_i, \cdot) \|_{L^2}^2 + \frac{h}{2} \| \rho_B' - \rho_B \|_{L^2}(39)
\]

onto the set \( \mathcal{C}E_h(\rho_A) \) of solutions of the discrete continuity equation with initial data \( \rho_A \) the following modifications apply. Analogous to Proposition 4.5, a space time discrete elliptic equation

\[
\frac{\rho_h(t_1, x) - \rho_h(t_0, x)}{h^2} + \Delta \rho_h(t_0, x) = - \left( \frac{\rho_h(t_1, x) - \rho_A(x)}{h} + \text{div} m_h(t_0, x) \right),
\]

\[
-\frac{\rho_h(t_{N-1}, x) - \rho_h(t_{N-2}, x)}{h^2} + \Delta \rho_h(t_{N-1}, x) = - \left( \frac{\rho_h(t_{N-1}, x) - \rho_h(t_{N-2}, x)}{h} + \text{div} m_h(t_{N-1}, x) \right),
\]

\[
\frac{\rho_h(t_{i+1}, x) - 2\rho_h(t_i, x) + \rho_h(t_{i-1}, x)}{h^2} + \Delta \rho_h(t_i, x) = - \left( \frac{\rho_h(t_{i+1}, x) - \rho_h(t_{i-1}, x)}{h} + \text{div} m_h(t_i, x) \right)
\]

with \( i = 1, \ldots, N-2 \) and \( x \in X \) has to be solved for the Lagrange multiplier \( \rho_h \in V^n \). Note that this system is no longer degenerate due to the additional freedom of \( \rho_B \) and thus no
regularization as before is required. Then the solution \((\rho^{pr}, m^{pr}, \rho_B^{pr})\) to (39) is given by

\[
\rho_B^{pr}(x) = \frac{1}{2} \left( \rho_h(t_{N_i}, x) + \rho_g(x) - \frac{\varphi_h(t_{N_i-1}, x)}{h} \right),
\]

\[
\rho_h^{pr}(t_i, x) = \rho_h(t_i, x) + \frac{\varphi_h(t_i, x) - \varphi_h(t_{i-1}, x)}{h},
\]

\[
\rho_B^{pr}(t_0, x) = \rho_A(x), \quad \rho_B^{pr}(t_N, x) = \rho_B^{pr}(x),
\]

\[
m_B^{pr}(t_i, x, y) = m_h(t_i, x, y) + \nabla X \varphi_h(t_i, x, y)
\]

for all \(i = 1, \ldots, N - 2\) and \(x, y \in \mathcal{X}\). In Figure 9 we compare the numerical results for this natural discretization of the gradient flow of the entropy to the flow computed numerically with a simple explicit Euler discretization applied to the heat equation and the Fokker-Planck equation, respectively, with respect to the underlying Markov kernel.

Figure 9: Numerical solution of the heat flow (top) and the Fokker-Planck equation (bottom) based on an explicit Euler scheme (blue) with time step size \(10^{-3}\) and for the gradient flow of the associated entropy using the logarithmic mean (red) and the geometric mean (green), respectively, with \(\tau = 10^{-3}\) and \(h = 100\). Panels on the left show the mass distributions on the graph at different times, panels on the right show the values of the entropies over time.
