Abstract
The fundamental question in the field of sensor research is new directions of scientific fields, which play a vital role in the progress of science and technology. This study confronts this question here by developing a bibliometric analysis, which endeavors to explain the evolution of sensor research and new technologies that are critical to science and society. The database of Scopus concerning scientific documents and patents is used for statistical and computational analyses in these topics. Results suggest that emerging technological trajectories in sensors are wireless sensor networks, wearable sensors and biosensors. Main characteristics of these growing research fields and technologies in sensors are described for fruitful implications of research and innovation policy directed to science advances and technological change in society.

Keywords:
Sensor research, Research fields, Evolution of science, Dynamics of science, Scientific development, Technological trajectories, Biosensors, Wearable sensors, Wireless sensor network.
1. Introduction

The evolution of sensor research and technology has critical aspects to science and human society (Rao et al., 2018; Sensors, 1992; Coccia and Bellitto, 2018). These topics of “The science of science” can clarify the driving factors of the evolution of science in sensors directed to support scientific discoveries and technological advances in society (Fortunato et al., 2018; Coccia 2020; Sun et al., 2013). First of all, a brief background of vital concepts in sensors is useful to clarify the study design here. A broad concept of sensor is a device, module or subsystem having the goal to detect events or changes in specific environment and send the information to other interrelated technological devises, such as a computer processor (Göpel et al., 1989; National Research Council, 1995; Rao et al., 2018). Sensors are technologies\(^1\) associated with different technologies, generating complex interactions in a perspective of host-parasite technological systems (cf., Coccia, 2018a, 2019, 2019a; Coccia and Watts, 2020). In particular, sensor system can be considered a parasite technology of other technological systems (Coccia, 2019; 2019a; Coccia and Watts, 2020). The parasitic technologies of sensors are systems that interact with the ecological system of the host (or master) technology (Elsisi et al., 2021; Kholod et al., 2021; Pereira et al., 2017). For instance, the sensors of inertial measuring unit and global positioning system are parasite technologies when installed in wearable (host) technology of consumer sports (Aroganam et al., 2019). Other types of parasite technologies of sensors are temperature sensors, proximity sensors, pressure sensors, etc. (Soy and Toy, 2021). In general, sensor technologies have parasitic relationships and multi-mode interactions with other technologies that support continuous evolutionary patterns of technological trajectories (Hudec et al., 2021; Suresh Kumar et al., 2021, Tatiparthi et al., 2021; cf., Coccia and Watts, 2020; Coccia, 2019, 2019a; Coccia, 2019b; 2019c; Coccia, 2020a; 2020c, 2020d; Dosi, 1988; Nelson, 2008). In fact, the progress in science and technology (e.g., artificial intelligence, solid-state electronics, optical computing and information processing, microelectromechanical systems, etc.) is supporting new types of sensors having improved performance for manifold needs of human activity (National Research Council, 1995). One of the most important advances in sensor technology is the development of smart or intelligent sensors, driven by convergence of technologies in machine learning, ubiquitous computing, etc. (Liu et al., 2021; Fan et al., 2021; Hussain, 2020; Rahimunnisa et al., 2021; Seymour et al., 2021; Yagoob and Younis, 2021; Soy and Toy, 2021; Suresh Kumar and Krishnamoorthi, 2021; Wang et al., 2021; Zhang et al., 2021). New studies show that smart sensors are crucial and integral elements in the Internet of Things (Alharbi et al., 2021; Banerjee et al., 2021, Davoli et al., 2021; Del-Vallesoto et al., 2021; Jo et al., 2021; Pal et al., 2020; Wang et al., 2021a). In addition, innovations in information and communication technologies, associated with the internet of things, have the potential to generate new sensors having applications in different fields (Abidoye and Kabaso, 2021; Coccia and Watts, 2020; Coccia, 2020b; Fang, 2021; Li et al., 2021). Hence, sensor research and technologies have a continuous evolution by the interaction with different and new research fields and technologies, generating innovative devices for sensing that are more and more networked and with aspects of artificial intelligence (Coccia, 2020d).

The main goal of this article is to analyze sensor research to explain the growth and main applications of new technologies for the technological and social change. Results here can clarify the dynamics of science in sensors that can be useful to policymakers for allocating resources and planning scientific and

---

\(^1\) Technology is a complex system, composed of more than one entity or sub-system of technologies and a relationship that holds between each entity and at least one other entity in the system for achieving specific goals (Coccia and Watts, 2020).
technological development having positive societal impact. This study is part of a large body of research on the evolution of science and technology that endeavors to explain how research fields and new technologies emerge and evolve in basic and applied sciences (Coccia, 2015, 2017a, 2017b, 2018, 2018, 2019b, 2020; Kashani & Roshani, 2019; Roshani et al., 2021; Scharnhorst et al., 2012; Sun et al., 2013).

2. Materials and Methods

2.1 Study design for technological trajectories

▪ Sources and Sample

The study uses datasets of Scopus (2021). In particular, the window of “Search documents” in Scopus (2021) database is used to identify scientific documents having in title, abstract or keywords of articles and patents the term "sensors". Scientific products and patents are the basic units for technology and scientific analyses to explain the evolution of science and technology in the field of sensors with fruitful policy implications.

▪ Measures

− Number of articles and all scientific products in “sensors” (conference papers, conference reviews, book chapters, short surveys, letters, etc.), 1955-2020 period.

Data under study here are 1,217,947 document results downloaded in April 2021. The scientific evolution of sensors and specific keywords, measured with the number of articles and other scientific products, can show the dynamics of sensor research.

Additional measure for the analysis of the evolution of sensor technology is:

− Number of patents, 1952-2020 period

Patents indicate inventions, and this study analyzes 1,226,074 units over the 1952-2020 period recorded for the field of sensors and its sub-fields.

▪ Specification of the model and data analysis procedure

The tool “Search documents” in Scopus (2021) provides keywords and time series of documents with the highest frequency in sensor research. After that, sensor technologies with the highest number of documents in the list of keywords have been selected, i.e.,:

− wireless sensor networks
− fiber optic sensors
− chemical sensors
− remote sensing
− biosensor
− wearable sensors
− image sensors
− wireless sensor
− optical sensors
− glucose sensors

Each of this keyword is inserted in the window “search documents” to detect the specific time series that
is used for a comparative analysis between sensor technologies in the list just mentioned to analyze the rate of growth and, as a consequence, new directions in sensor research. The study applies the model by Sahal (1981) for scientific and technology analysis of time series in sensor.

Two models are specified as follows.

Firstly,  
\[
\log y_{i,t} = a + b \text{ time} + u_t 
\]

\( y_t \) is the dependent variable of scientific products or patents. 
\( a \) is a constant; \( b \) is the coefficient of regression; The parameters \( a \) and \( b \) are unknown and are estimated using the sample of data. 
\( \log \) has base \( e = 2.7182818 \); 
\( t = \text{time} \); \( u_t = \text{error term in equation} \).

Secondly, if we consider the ratio: 
\[
\delta_{i,t} = \frac{\text{number of publications (or patents) in the subfield } i \text{ of sensors at } t}{\text{Total number of publications (or patents) at } t}
\]

The specification of the model is:

\[
\log \delta_{i,t} = a' + b' \text{ time} + \varepsilon_t 
\]

The equation [2] also has \( a' = \text{constant} \); \( b' = \text{coefficient of regression (} a' \text{ and } b' \text{ are the parameters to be estimated)} \); \( t = \text{time} \); \( \varepsilon_t = \text{error term in equation} \).

The relationships under study here for scientific and technology analysis are investigated using the Ordinary Least Squares (OLS) method for estimating the unknown parameters in regression models [1] and [2]. Statistical analyses are performed with the IBM SPSS Statistics 26 ®.

2.2 Technological analysis within research fields of sensors to detect technological characteristics and applications

- Research settings
The methodology here has the purpose to investigate the structure of emerging research fields in sensor technology, detected with previous statistical analysis by the highest coefficients of regression of estimated relationships based on publication and patent data (equations [1] and [2]); in particular, the magnitude of coefficients of regression is a proxy of high evolutionary growth of sensor research over time. Emerging research fields under study here, having the highest coefficients of regression, are given by:

- **wireless sensor network.** A wireless sensor network is a group of objects that transfer the gathered data through multiple nodes and wireless infrastructure to cooperatively sense and control the environment (Yick, 2008). These devices are positioned in large numbers, so they need the ability to assist each other to transfer data back to a centralized collection point (Rajaravivarma, 2003).

- **wearable sensors.** Wearable sensors are integrated into wearable objects attached to the body in health monitoring or physically relevant data collection. They have diagnostic and monitoring applications, including physiological and biochemical sensing and motion sensing (Teng, 2008). Wearable sensor adaptation has involved miniaturizing sensing technologies, making them...
conformal and flexible, and developing companion software that increases the value of the measured data (Heikenfeld, 2018).

**Biosensors.** A biosensor is an analytical device that measures biological or chemical sensing elements and reactions. They are generally employed in monitoring, pollutants detection, and biomarkers discovery (Kissinger, 2005). They restrain biology’s great sensitivity and specificity in intersection with physicochemical transducers to provide detailed and bioanalytical measurements with easy-to-use and straightforward formats (Turner, 2013).

This section applies Natural Language Processing (NLP) to demonstrate common research themes in emerging subfields of the sensor, just mentioned (i.e., wireless sensor network, wearable sensors and biosensors). In the document type section of the Scopus dataset (Scopus, 2021a), the data of conference paper, article, conference review, and review have been collected. Among statistical algorithms, topic modelling as a text-mining tool can help to discover and organize latent topics. This modelling allows us to create an extensive text body’s semantic structures through various disciplines correlations (Jiang et al., 2016). We implemented the Latent Dirichlet Allocation (LDA) as an unsupervised approach for topic modelling (i.e., machine learning -LDA) that attract popularity in textual data processing due to its ability to reduce the bias and increase the accuracy for literature investigation (Blei et al., 2003). Moreover, we used java implementation of this model with the name MALLET (McCallum, 2002). In this study, we used the Python programming language for building a topic model. The methodology has been accomplished in three steps: (1) data gathering and text pre-processing, (2) topic construction, and (3) investigation, which are explained in more details.

- Sources of data, sample and measures of computational analyses

This study, as said, uses data from Scopus (2021a). According to search procedures, we have obtained:

- 1,989 publications in wireless sensor networks published from 1989 to the end of 2020, including keywords in articles’ keywords, abstract and title.
- 71,780 articles in wearable sensors published from 1998 to 2020.
- 66,996 documents in biosensor published from 1970 to 2020.

After an initial review of these articles, the abstracts were used to input the LDA technique to explore topics under study. Measures are similar and described in previous section.

- Topic modelling and data analysis procedure
  - Step 1: data gathering and text pre-processing

This study employed data from the Scopus (2021) database. For collecting the related documents, we used the search string TITLE-ABS-KEY("wearable sensor") for wearable sensor papers, TITLE-ABS-KEY("Biosensor") for Biosensor papers, and TITLE-ABS-KEY("Wireless sensor network") for Wireless sensor network documents. All publications have been collected until 2020, and for increasing the accuracy of data, this study has limited the records to conference papers, article, conference reviews, and reviews in English.
Secondly, for textual data pre-processing, we conducted a topic modelling analysis using Python 3.7.7 version programming language to first concatenating all abstracts of publications and then concatenating them into one string set for each field. We created a corpus of the respective field documents by which the model learns the ‘topics’. The data are pre-processed prior to the topic modelling using GenSim library (Rehurek, 2010) to convert each publication’s abstract into a bag-of-words representation. We consider each word as a token and then eliminated words in a stopword list provided in the MALLET software (McCallum, 2002). Then, words with a low frequency, fewer than three characters have got removed. We exerted the Tokenization technique by splitting the text into a set of words, punctuation removal, adjusting the terms with higher cases into lowercase. Aside from those processes, we implement lemmatization to assimilate all the verbs in various tenses to present tenses and modified them to the first person. In the end, we removed all terms that appear fewer than ten times across all documents, or that appear in more than 70 percent of records.

- **Step 2: topic construction**

We can assume a topic as a probability distribution over a term. Those vocabularies with a high probability of occurrence in the same topic are more likely to appear frequently in the same documents simultaneously. For constructing the topic, we started training the model using MALLET, a Java-based package used for statistical NLP developed by McCullum (2002) to build a Latent Dirichlet Allocation model (LDA). This model requires a fixed number of topics that is not specified accurately for a corpus. Accordingly, we chose an optimal number of topics for implementing the topic modelling technique following the study by Mifrah and Benlahmar (2020). In this respect, we calculated the topic coherence score for each number of topics to identify the most efficient one. We used the C_v coherence measure to retrieve co-occurrence counts of respective word sets based on the sliding window size. We calculated the normalized pointwise mutual information (NPMI) for every top word to every top word to extract a set of vectors for each top word. Afterwards, we measured the similarity between the top words sum vector and each top word vector in one-set segmentation. We utilized cosine similarity to calculate the coherence score based on an arithmetic mean of all similarities (Mifrah and Benlahmar, 2020). We calculated the coherence of a couple of models through different numbers of topics according to the approach of Röder (2015) to identify the best number of topics for our model applied in the present study. Figure 1 demonstrates the coherence score of the model through the different numbers of topics.

For wearable sensors, results show that the highest coherence value (i.e., 0.5546) occurs in topic number 22, for biosensors, the highest coherence value (i.e., 0.5687) occurs in topic number 32, and for wireless sensor network, the greatest coherence value (i.e., 0.5260) stands for topic number 38.

![Figure 1](image.png)

**Figure 1.** Topic coherence score with a different number of topics in wearable sensor, biosensor, and wireless network sensor with the sliding window size of 100.

- **Step 3: investigation**

In this step, the study here investigated topics of the emerging research fields in sensor technology described before: wireless sensor network; wearable sensors and biosensors. This section presents
topic modeling findings using a world-cloud demonstration in which the size of each word in a specific topic is according to its frequency in that topic. Afterward, we classified all the topics of each field into two categories:  technological characteristics and applications. In the second part of the results, trend analysis was conducted separately to demonstrate their evolutionary growth based on the popularity of topics over time. Evolutionary growth of topics within each research field under study (wireless sensor network, wearable sensors, and biosensors) has been categorized in Positive Evolutionary Growth, Stable Evolutionary Growth, and Negative Evolutionary Growth to assess the topic trend analysis for the classification of each emerging subfields of the sensor. In particular,

- 'Positive Evolutionary Growth' indicates that the topic popularity has been increasing, and the occurrence frequency of the topic words has been elevating.

- 'Stable Evolutionary Growth' indicates that the topic popularity has been fluctuating and doesn't follow a rising or falling trend. It means that the occurrence frequency of the words in the topic has stable evolution.

- 'Negative Evolutionary Growth' indicates that the topic popularity has been decreasing, and the occurrence frequency of the topic words has been faced reduction.

3. Results and Discussion

3.1 Growth of research fields in sensors

The parametric estimates of models [1-2], based on scientific production, are presented in Table 1. In a majority of cases, the significance of the coefficients of regression and the explanatory power of the equations has p-value<.001. The R² values are high and in general the models explain more than 80% variance in the data.
Table 1 – Estimated relationships of scientific production in research fields of sensors as a function of time

| Research fields            | Coefficient $b_1$ | Constant $a$  | $F$       | $R^2$ | $N$, period     |

*** significant at 1‰; ** significant at 1%, * significant at 5%. $F$ is the ratio of the variance explained by the model to the unexplained variance; $R^2$ is the coefficient of determination adj.
Table 3, using the coefficients of regression of models calculated in table 1 and 2 (trends are displayed in Figure 2 and 3), suggests that the emerging research fields in sensors are:

- wireless sensor networks
- wearable sensors
- biosensors.

Results also suggest that wireless sensors, a restriction of wireless sensor networks, has a high evolutionary growth in the field of sensor technology. All these research fields are the younger ones among research fields in sensors. This result is consistent with studies by Coccia (2018, 2020) that higher growth rates of scientific production are in new research fields rather than old ones.

Table 3 – Evolutionary growth of scientific fields in sensor technology based on coefficients of regression considering the number of publications and patents over time, and their scientific age from the first scientific products to the year 2020

| Research fields            | Coefficient of Publication | Age | Research fields            | Coefficient of patents | Age |
|----------------------------|----------------------------|-----|----------------------------|------------------------|-----|

Figure 2. Trends of research fields in sensors using scientific production (log scale)
The next section investigates these research fields and technologies to clarify their structure and drivers in science dynamics to detect critical technological characteristics and applications for progress in society and society.

3.2 Structure, characteristics, and applications of critical research fields in sensors

The results of topic modelling analysis demonstrate the top 15 high-frequency terms in each topic. These topics contain the words reflecting the content and terms of documents with the highest score. The topics are related to significant issues in each growing subfield in sensor technology. We illustrated 38 topics in wireless sensor network, 22 topics in wearable sensors, and 32 topics in biosensors through a world-cloud analysis; the size of each word indicates comparatively the frequency weight of a term in a specific case. The larger the word, the higher the frequency stands in the parent topic. Accordingly, this visualization can reflect the brief information of each topic and partially explains the included documents. Ultimately, this study analyzes and explores the evolution of these topics over time. Topic modeling analysis can also demonstrate the increasing or decreasing popularity of topics, which can better explain how a field of research has been changing over time. We normalized the proportion of each topic per year and obtained the annual trends.

wireless sensor network

Figure 4 shows the 20 most frequent words that appeared in publications on wireless sensor network. Our results show that the terms “network”, “node”, “wireless”, and “energy” have been used more than 100,000 times across the corpus. Each word, according to its similarity regarding the co-occurrence, leads to topics creation.
Figure 4. The highest frequent words in the wireless sensor network documents

Figure 5 shows the topic's classification of the wireless sensor network. The largest words of each class represent the content of the topic documents. Figure 5 of Word-Cloud analysis suggests information about technological characteristics and applications of wireless network sensor. In particular, main technological characteristics of wireless sensor networks are (from Figure 5):

- Internet of things
- network optimization
- data security
- monitoring system
- optimization
- technical infrastructure

Instead, the main application characteristics of wireless sensor networks are (from Figure 5):

- environmental monitoring,
- communication systems
- energy
- smart vehicles
- control systems
- healthcare
Figure 5. World-Cloud of wireless sensor network

Table 4 shows the evolutionary growth of topics in wireless network sensor. From this classification, it can be concluded that the studies of smart sensors associated with the Internet of things are growing; the studies of environmental monitoring and health care evolutionary level are also increasing over time.
Table 4. Dynamics of trends in wireless sensor network using trend analysis

| Evolutionary Growth                      | Number of Topics                                                                 |
|------------------------------------------|----------------------------------------------------------------------------------|
| Positive Evolutionary Growth             | 3(smart device, internet of things, etc.), 5(environmental, water, temperature, monitor, etc.), 24(future, potential, challenge, etc.), 28(system, human, health, etc.), 33(WSN, technique, business, etc.) |
| Stable Evolutionary Growth               | 1(resource, reliability, etc.), 2(target, track, etc.), 4(fusion, distribution, etc.), 6(node, neighbor, etc.), 7(service framework, architecture, etc.), 8(information, report, etc.), 9(power, low, battery, etc.), 10(datum, aggregation, transmit, etc.), 11(attack, detection, trust, etc.), 12(localization, position, location, etc.), 13(scheme, security, communication, etc.), 14(image, signal, etc.), 15(schedule, phase cycle, etc.), 16(structure, test, measure, etc.), 17(radio, frequency, communication, etc.), 18(energy, consumption, etc.), 19(sink, mobility, node, etc.), 20(real, time, etc.), 21(energy, head, cluster, etc.), 23(platform, software, hardware, etc.), 25(system, vehicle, machine, etc.), 26(deployment, coverage, area, etc.), 27(control dynamic, level, etc.), 29(human, system, body, etc.), 30(transmission, access, layer, etc.), 31(protocol, route, path, etc.), 32(algorithm, problem, optimization, etc.), 34(traffic, packet, delay, etc.), 35(relay, code, scheme, etc.), 36(monitoring, system, etc.), 37(performance, evolution, simulation, etc.), 38(distribution, local task, strategy, etc.) |
| Negative Evolutionary Growth             | 22(topology, algorithm, tree, etc.)                                              |

This study reveals that networking of sensor systems are growing over time (Fang et al., 2021; Clavijo-Rodriguez et al., 2021; Del-Valle-soto et al., 2021; Bravo-Arrabal et al., 2021; Sunny et al., 2021). Results here also suggest that wireless sensor networks have a higher rate of evolution likely because of the interaction with specific technologies, such as Internet of things, data security and monitoring system. In the context of technological applications, these sensors have a growing application in environmental monitoring and healthcare (Hassan et al., 2020; Lanzolla and Spadavecchia, 2021; Naranjo-Hernández et al., 2020; Nasser et al., 2021). A critical aspect in these sensors is the maintenance, and many sensor wireless systems are powered with batteries or self-powering technology. Ultra-low-power sensors are a desirable option because they can reduce the need for regular battery changes and support a higher technological sustainability in environment (Ari et al., 2018). Finally, technology of wireless network sensor has the advantage of easy upgrades of new technological characteristics; consequently, the technological system can be more efficient from a technological and economic point of view (Abidoye and Kabaso, 2021; Jasim et al., 2021).
Wearable Sensor

Figure 6 shows the top 20 words with the highest frequency in wearable sensor publications. These findings reveal that the terms "system", "device", "datum", "time", and "human" have appeared more than 6,000 times across the corpus.

Figure 6. The highest frequent words in the wearable sensor documents

Figure 7 illustrates 22 topics of wearable sensor documents by interpreting the most important words with the highest frequency of occurrence. Each category represents contained publications. A more comprehensive insight from this analysis shows the categorizations of topics according to technological characteristics and applications of sensors. In particular, critical technological characteristics of wearable sensors are (Figure 7):

- sensor particles
- machine learning
- monitoring
- biosensing technologies
- pressure sensing,
- detection technologies
- sensor network

Instead, the application characteristics of wearable sensors are (Figure 7):

- energy and power
- physical activities
- medical science
- psychology
Table 5 shows the positive popularity rate of wearable sensor technologies over time, such as sensor particles, machine learning, and pressure sensing. The growing application topics are mainly physical activities and body motion measuring.

Table 5. Dynamics of trends in wearable sensor using trend analysis

| Number of Topics |
|------------------|
| **Positive Evolutionary Growth** |
| 1 (electronic, electrode, temperature, etc.), 4 (datum, recognition, machine learning, etc.), 9 (pressure sensing, range, etc.), 11 (measure, physical, risk, etc.), 16 (strain, flexible, material, etc.) |
| **Stable Evolutionary Growth** |
| 2 (sense, control, robot, etc.), 5 (future, technology, challenge, etc.), 6 (patient, clinical, etc.), 7 (change, measurement, etc.), 14 (stress, level, etc.), 15 (training, movement, exercise, etc.), 19 (estimate, gait, walk, etc.), 20 (performance, accuracy, accelerometer, etc.), 21 (signal, heart rate, etc.), 22 (motion, human, etc.) |
| **Negative Evolutionary Growth** |
| 3 (environment, system, position), 8 (datum, mobile, smartphone, etc.), 10 (power, energy, battery), 12 (wireless, network, body, etc.), 13 (healthcare, system, monitoring, etc.), 17 (smart, device, real-time, etc.), 18 (detection, daily, system) |

This study also shows that studies on wearable sensor are growing significantly in detection and monitoring technologies. Since wearable sensors can be assumed as biosensors connected to the body, assessing different biological elements, the health care system is one of the essential applications (Chen et al., 2021; Feng et al., 2021; Kouis et al., 2021). In fact, the embedding of wearable sensor systems in health treatment procedures reduces the cost of hospitals’ daily expenditures, including patient monitoring and vital sign measurement. These facilities enable doctors to remotely monitor patients’
health conditions, reducing extended stay and hospital maintenance costs (Babu and Shanthalrajah, 2021; Convertino et al., 2021; Park et al., 2021). Results also suggest that pressure sensing is a main technological characteristic of wearable sensors (Lee et al., 2020; Mishra et al., 2021). However, wearable sensors are still facing several challenges. One of the most problematic issues is related to the adaptability of sensors to the body to be comfortable in body-worn devices. This study confirms that flexible, stretching, and soft technologies are growing to enable wearable devices to be more usable in daily life activities (Zhao et al., 2020). Such technologies and human motion sensing analysis studies are rising because of the importance of disabled people’s living conditions enhancement, (Čuljak et al., 2020; Haque et al., 2021). In this context, results here suggest that future developments are directed to improve material flexibility, softness, and comfort of the wearable technologies (e.g., artificial legs and hands devices) to be used properly in patients (Chheng and Wilson, 2021).

- biosensors

Figure 8 shows the 20 words with the highest occurrence across biosensors. Our findings reveal that the terms "biosensor", "detection", "base", "sensor", "surface", "cell", and "high" have the highest frequency, appearing more than 30,000 times in the corpus. These high-frequent words’ similarity regarding their co-occurrence matrix have been considered in topic creations.

Figure 8. The highest frequent words in the biosensor network documents

Figure 9 illustrates 32 topics of biosensor documents. The largest words with the highest occurrence frequency in each category partially represent the content of the contained documents. Topics of the biosensor, visualized in figure 9, can be also categorized in technological characteristics and applications to see technology-oriented and application-oriented aspects of this research and technological field. Main technological characteristics of biosensors are (Figure 9):

- measurement sensors
- electrochemical sensors
- detection technologies
- network sensors
- optical sensors
nanotechnology

Instead, main application characteristics of biosensors are (cf., Figure 9):

- genetic
- DNA sequence
- vital sign measurement
- cancer detection
- patient monitoring

Figure 9. Cloud words of biosensor

Table 6 shows that material science, nanotechnology, and the detection process have been growing in sensor research to expand the technological aspects of biosensors. On the contrary, this analysis demonstrates that the glucose sensors topic faced a considerable reduction in its popularity.
The results here also demonstrate that biosensor studies are growing over time, especially in topics associated with detecting and monitoring applications in medical systems (Nejadmansouri et al., 2021). In fact, nanosensor technologies have started interacting with other technologies, improving the efficiency of biosensor performance to reduce human error in disease detection and the cost of human resource in the health care industry (Banerjee et al., 2021; Naresh and Lee, 2021). One of the aspects that supports the growth of biosensor is the emergence of biochemical sensors containing active materials in their chemical structures to assess biological or chemical reactions by signals generation to identify and measure the concentration of an analyte in the reaction. These technologies have been utilized mainly for detection purposes, including biomarker detection for blood, glucose level, food mass, anti-body detection, genetic aspects, etc. (Baluta et al., 2021; Holzer et al., 2021; Hong et al., 2020). We should also consider that the COVID-19 pandemic crisis has changed health systems requiring a rapid detection using immuno-sensor and remote patient monitoring (Mojsoska et al., 2021). In fact, one of the fundamental problems in pandemic control is the insufficient capacity of hospitals to hospitalize, at the same time, infected individuals with serious symptoms of COVID-19 (Coccia, 2021). The biosensor devices enable doctors to monitor and treat remotely patients in their house, instead of in the hospital, helping the healthcare management of patients, reducing costs and the negative effects of this novel coronavirus in society. Hence, the biosensor is gaining momentum to detect and monitor remotely COVID-19 affected patients, patients with other disorders and/or post-surgical patients to reduce the overall cost of healthcare and improve the efficiency of hospitals (cf., Ardito et al., 2021; Laghib et al., 2021, Restrepo et al., 2021; Shahbazi et al., 2021; Stuart et al., 2021; Taha et al., 2020).

The results here also demonstrate that biosensor studies are growing over time, especially in topics associated with detecting and monitoring applications in medical systems (Nejadmansouri et al., 2021). In fact, nanosensor technologies have started interacting with other technologies, improving the efficiency of biosensor performance to reduce human error in disease detection and the cost of human resource in the health care industry (Banerjee et al., 2021; Naresh and Lee, 2021). One of the aspects that supports the growth of biosensor is the emergence of biochemical sensors containing active materials in their chemical structures to assess biological or chemical reactions by signals generation to identify and measure the concentration of an analyte in the reaction. These technologies have been utilized mainly for detection purposes, including biomarker detection for blood, glucose level, food mass, anti-body detection, genetic aspects, etc. (Baluta et al., 2021; Holzer et al., 2021; Hong et al., 2020). We should also consider that the COVID-19 pandemic crisis has changed health systems requiring a rapid detection using immuno-sensor and remote patient monitoring (Mojsoska et al., 2021). In fact, one of the fundamental problems in pandemic control is the insufficient capacity of hospitals to hospitalize, at the same time, infected individuals with serious symptoms of COVID-19 (Coccia, 2021). The biosensor devices enable doctors to monitor and treat remotely patients in their house, instead of in the hospital, helping the healthcare management of patients, reducing costs and the negative effects of this novel coronavirus in society. Hence, the biosensor is gaining momentum to detect and monitor remotely COVID-19 affected patients, patients with other disorders and/or post-surgical patients to reduce the overall cost of healthcare and improve the efficiency of hospitals (cf., Ardito et al., 2021; Laghib et al., 2021, Restrepo et al., 2021; Shahbazi et al., 2021; Stuart et al., 2021; Taha et al., 2020).
4. Conclusions, limitations and prospects

This study shows that in sensor research, high growth rates are associated with research fields of wireless sensor network, wearable sensor and biosensor, supporting new directions to scientific and technological development. In particular, this study reveals that technological development of sensor is due to evolutionary pathways based on sensors having interactions with other technological systems, such as Internet of things, pervasive computing, etc. (Alharbi et al., 2021; Banerjee et al., 2021; Davoli et al., 2021; Del-Valle-soto et al., 2021; Elsisi et al., 2021; Jo et al., 2021; Kholod et al., 2021; Pal et al., 2020; Pereira et al., 2017; Wang et al., 2021). Results suggest that sensors have, as parasite technologies (Coccia and Watts, 2019), a wide spectrum of applications from health monitoring to aircraft and automotive industries (George et al., 2021; Morales et al., 2021; Zanelli et al., 2021; Zelenika et al., 2021; Zhang et al., 2021a). Moreover, the successful of smart sensors, smart objects, and cyber-physical systems are associated with the integration of the Internet of Things, through which it is possible to connect devices and exchange information among people, systems, and devices (da Costa et al., 2021). Historically, research and development (R&D) efforts in sensor technology have been funded as an adjunct to large application programs that required sensors (National Research Council, 1995). Now, selected R&D investments support the development of new and improved sensors with effective research planning processes directed to users for specific applications (Mee et al., 2021). The description of technological characteristics of sensors, described here, associated with performance capabilities and sensor applications in different settings can improve the allocation of R&D investments in private and public organizations for scientific and technological development (Coccia, 2017c).

This study also shows that sensor research is a vast research field in continuous evolution because of recent advances in information and communication technologies, artificial intelligence, nanoscience, human-computer interaction, that enable intensive interactions of sensor technology with other disciplines and new technologies. Overall, then, this study maintains that growing fields in sensor research are given by wireless sensor network, wearable sensor and biosensor with new applications in environmental, sustainability and health sciences. However, these conclusions here are of course tentative. We know that other things are not equal in the dynamics of sensor research and there is need for much more detailed examinations that focus on novel sensing and interfacing technologies to explain new directions in the design, implementation, and evaluation of interactive technology of sensors in society. The future development of this study is directed to reinforce proposed results with additional data extending the empirical studies on the use of advanced intelligent sensors in ambient and pervasive computing interaction, such as smart environments, human-machine interaction and/or virtual and augmented reality.
