Supplementary Information

Experimental section

Materials

Poly(vinylidene Fluoride) (PVDF) (Mw = 53,4000 g/mol), 3,4,9,10-perylenetetracarboxylic dianhydride and tridecan-7-amine were purchased from Alfa Aesar. Aniline, imidazole, dichloromethane, n-hexane, acetone, dimethylformamide (DMF) toluene, methanol, and acetic ether were purchased from Beijing Chemical Works and used without further purification. N-butylamine, dibutylamine, 1-hexamine, cyclohexamine, isoctamine, benzylamine, 4-methylaniline, 4-fluoroaniline, 4-nitroaniline, phenol were purchased from Innochem.

Instruments

$^1$H and $^{13}$C nuclear magnetic resonance (NMR) spectra were recorded on Bruker AV spectrometer operating at 300 and 75 MHz using deuterated solvents. Relative Molecular Mass was recorded on Bruker ultraflextreme MALDI-TOF. Scanning electron microscopy (SEM) images were collected on S4800 (HITACHI) at 1.5 kV and 1.0 kV. Transmission electron microscopy (TEM) images were collected on JEM-1400 (JEOL) at 100 kV. Samples for TEM measurements were prepared by dropping the solution of PDI@PVDF (the solution was prepared by adding a small amount of PDI@PVDF fibre to 10 ml ethanol with ultrasonic stirring for 20 minutes) onto a copper grid. Fluorescence spectra were measured by fluorescence spectrophotometer (F-7000, HITACHI and ATP 2000, OPTOSKY). UV-vis absorption spectra were recorded on HP 8453 UV-Vis spectrophotometer. Diffraction experiments were performed on a vertical scan Bruker AXS D8 Advance. Fluorescence decay profiles were recorded on Edinburgh FLS980 spectrometer.

Synthesis of compound PDI

3,4,9,10-Perylenetetracarboxylic dianhydride (0.98 g, 2.5 mmol), tridecan-7-amine (1.99 g, 10 mmol), and imidazole (8.00g) were mixed in flask with three necks (100 mL). The solution was stirred at 140°C for 5h under nitrogen protection. Then, ethanol (20mL) was added to it until the solution was cooled to 80°C. Next, the solution added with hydrochloric acid (2 M, 70mL) at room temperature was stirred overnight. Then the solution was filtered , washed to neutral with ethanol and distilled water, and obtained red solid was treated by vacuum drying at 60°C. The residue was purified by column silica gel chromatography with the eluents of dichloromethane/n-hexane (1/3, v/v) to obtain PDI as the red solid. Yield: 90%. $^1$H NMR (CDCl$_3$, 300 MHz, ppm): δ 8.66 (d, $J$ = 11.4 Hz, 8H), 5.19 (s, 2H), 2.24 (d, $J$ = 11.7 Hz, 4H), 1.86 (s, 4H), 1.49 - 1.02 (m, 32H), 0.81 (d, $J$ = 6.5 Hz, 12H). $^{13}$C NMR (CDCl$_3$, 400 MHz): 14.10, 22.02, 26.95, 29.25, 31.79, 32.38, 54.78, 123.08, 126.47, 129.62, 131.20, 134.55. MALDI-TOF: calcd. for C$_{50}$H$_{62}$N$_2$O$_4$ [M]$^+$, 754.471; found, 754.223.
Preparation of Electrospun Nanofibers

To prepare a precursor solution for synthesizing the electrospun nanofibers, 100mg of PDI were independently dissolved in 4.0 mL of DMF. In each case, when the solute was completely dissolved, 2.00 g of PVDF as a matrix polymer was added, and the resulting mixture was stirred and loaded into a stainless steel syringe connected to a needle of gauge 19. The distance between the end of the needle and grounded plate was adjusted to be 15 cm before applying 12.00 kV. The precursor solution was ejected to form fine fibers on the surface of a grounded aluminum plate located 15 cm below the tip of the needle. The flow rate was carefully kept at 2.0 ml/h. After collection, the polymer fibers were dried in a 40 °C vacuum oven for 1 d to prevent agglomeration.

Solid-State Fluorescence Sensing Experiments

The PDI@PVDF film was fixed on a special designed scaffold then covered with a quartz cell (Fig. S12). A 365nm LED lamp was used to excite the film, and the fluorescence variation (λ=630nm) in the presence of organic amines was continuously monitored by a spectrometer. In order to obtain saturated vapor, a small amount of amine is sealed in a sealed sample bottle for overnight to obtain saturated vapor. The diluted vapor of aniline was obtained in a sealed air bag, into which a small volume of the saturated vapor of aniline was injected (using an air-tight glass syringe) to achieve the diluted vapor. For example, injection of 14 mL of saturated aniline vapor (880 ppm) into the 5 L air bag will produce a vapor pressure 714 times diluted (about 1.25 ppm). The lowest vapor pressure of aniline that can be achieved through vapor dilution was about 0.4 ppb, for which two steps of dilution were carried out, i.e., 5 mL of the saturated vapor of aniline was injected into a 5 L air bag, followed by injecting 2 mL of this diluted vapor into other 5 L air bag.
