Abstract: Maximberus maxi n. gen., n. sp. is described and illustrated based on adult males from Mata Atlântica in Southern and Southeastern Brazil. This genus can be separated from other Orthocladiinae on the combination of bare eyes, wing, and squama; no acrostichals; R₄+₅ ending proximal to M₃+₄; comb of setae on hind tibiae composed of few thin setae; well developed anal point; and virga composed of bundles of flattened spines attached to the oral part of the penis cavity.

Keywords: Chironomidae, Orthocladiinae, Maximberus, new genus, new species, Brazil, Neotropical region, Mata Atlântica.

ANDERSEN, T. & MENDES, H.F. Maximberus maxi n. gen., n. sp. do sul e sudeste do Brasil (Diptera: Chironomidae, Orthocladiinae). Biota Neotrop. 12(1): http://www.biotaneotropica.org.br/v12n1/pt/abstract?article+bn01512012012

Resumo: Maximberus maxi n. gen., n. sp. é descrita e ilustrada com base no macho adulto coletado na Mata Atlântica do sul e sudeste do Brasil. Este gênero pode ser separado dos demais Orthocladiinae com base na combinação de olhos, asas e squama sem pelos; setas acrosticais ausentes; R₄+₅ terminando proximal a M₃+₄; pente de setas na tíbia posterior composto por poucas setas finas; ponta anal bem desenvolvida; virga composta de um agrupamento de espinhos achatados fundidos a parte anterior da cavidade peniana.

Palavras-chave: Chironomidae, Orthocladiinae, Maximberus, gênero novo, espécie nova, Brasil, região Neotropical, Mata Atlântica.
Introduction

The number of orthoclad species known from Brazil has increased rapidly during the last decade. In their catalog of the Neotropical and Mexican chironomids Spies & Reiss (1996) recorded seven Orthocladiinae species from Brazil; one of these, Ichthyocladius neotropicalis Fittkau, as uncertain, a species which later has proved not to occur in Brazil (Mendes et al. 2004). Ten years later Mendes et al. (2007) listed 37 species of orthoclads, while today about 100 species are known to occur in Brazil (Mendes & Pinho 2011). Several genera are so far only recorded from Brazil, viz. Gynocladius Mendes, Sæther et Andrade-Mourray, Iporangomerus Mendes et Andersen, Lyrocladius Mendes et Andersen, Oleia Andersen et Mendes, Saetherocladius Andersen et Mendes, Saethercryptus Andersen et Mendes, Saetherolabis Andersen et Mendes, Saetherops Andersen et Mendes, and Ubatabaneura Wiedenbrug et Trivinho-Strixino, but a wider distribution of several of these genera is to be expected.

However, a high number of new species still await description. When collecting in Brazil many of the orthoclads encountered do not readily fit into any described genus. Several of these might be terrestrial or semiterrestrial and the larvae and pupae might be difficult to locate. Below we describe the males of one of these species and place it in a new genus. The species was taken in Malaise traps in Mata Atlântica in Southern and Southeastern Brazil during the BIOTA–FAPESP project “Limites geográficos e fatores causais de endemismo na Floresta Atlântica em Diptera”.

Material and Methods

The specimens were mounted in Canada Balsam following the procedures outlined by Sæther (1969). The general morphology follows Sæther (1980). Measurements are given as ranges followed by the mean when four or more specimens were measured.

The types will be deposited in Museu de Zoologia da Universidade de São Paulo (MZUSP) and in the Department of Natural History, University Museum of Bergen, University of Bergen, Bergen, Norway (ZMBN).

Maximberus n. gen

Type species: Maximberus maxi n. sp.

Etymology: Named after the senior author’s one and a half year old grandson Max Rieber-Mohn for all interruptions while drawing the species; and Tupi mberui, midge, mosquito; meaning Max’s midge. Gender of the genus name: masculine.

Diagnostic characters: The combination of bare eyes, wing, and squama; no acrostichals; R4+5 ending proximal to M1+2; comb of setae on hind tibiae composed of few thin setae; well developed anal point and virga composed of bundles of flattened spines attached to the oral part of the penis cavity will separate the genus from all other orthoclads.

Description: Small sized species, wing length 0.70-0.94 mm.

Head. Eyes bare, reniform, without dorsomedian extension. Antenna with 12 flagellomeres; sparsely plumed; groove beginning on segment 2; sensilla chaetica present on flagellomeres 2, 3, and ultimate; without subapical seta. Palpomeres normal, third palpomere with few sensilla clavata subapically. Temporal setae in single row, inner verticals weak, outer verticals and postorbitals strong. Frontal tubercle absent. Tentorium and stipes normal. Cibarial pump with anterior margin weakly concave. Clypeus with few setae.

Thorax. Antepenultimate well developed with lobes meeting medially at anterior margin of scutum. Acrostichals absent; dorso cercals simple, uniserial; prealars uniserial; supraalar present. Scutellum with few setae in single row.

Wing. Membrane without setae, with fine punctuation, microtrichia visible at 400 times magnification. Anal lobe weakly developed. Costa extended; R ending proximal to M1+2; FCu distal to RM; Cu, slightly sinuous. Brachiolium with 1 seta, other veins bare. Squama bare. Sensilla campaniformia about 9 apically, 6 basally, and 3 above seta on brachiolum; 1 on RM; and 1 basally on R4+5.

Leg. Tibial spurs normal, comb of hind tibia composed of weak setae. Tarsal pseudospurs and sensilla chaetica absent. Pulvilli vestigial.

Abdomen. Abdominal setation reduced. Tergite I bare, tergites II-VIII with two irregular rows of few setae. Sternite I-III bare, sternite IV-VIII with few setae medially.

Hypopygium. Anal point well developed, tapered with rounded apex, with microtrichria and lateral setae. Tergite IX without setae; laterosternite IX with few setae. Apodemes well sclerotized. Phallapodeme with posterior, narrow, curved lobe; aedeagal lobe normal. Transverse sternapodeme arched, oral projections barely indicated. Penis cavity with horse-shoe shaped basal sclerite; virga consisting of 4-8 bundles of 1-4 separate, flattened spines attached to the penis cavity. Gonocoile with weakly developed inferior volsella. Gonostylus curved, covered with microtrichia and with few setae; megaseta normal; crista dorsalis absent.

Female, pupa and larva. Unknown.

Systematics

The genus does not key to any specific genus either in Cranston et al. (1989) nor in Spies et al. (2009); in the former it will key to couplet 97, if costa is considered to be not to moderately extended it will key to couplet 102; in the latter it will key to couplet 122.

The genus shows some similarities with Psilometriocnemus Sæther, especially the lack of acrostichals, bare wing membrane with fine punctuation, squama without setae, and anal point with lateral setae. However it can easily be separated from Psilometriocnemus based on the shape of the virga, absence of crista dorsalis, and R4+5 ending proximal to M1+2. A position in the group that includes the genera Heterotrissocladius Späck, Parametriocnemus Goetheguber, Paraphaenocladius Thienemann, Platysmitthia Sæther and Psilometriocnemus Sæther does not seem unlikely.

Maximberus maxi n. sp. (Figures 1-15)

Type material: Holotype male: BRAZIL, São Catarina State, São Bento do Sul, 26° 19’ 25.6” S and 48° 18’ 26.5” W, 13-16.x.2001, 660 m a.s.l., Malaise trap (Trilha Rugendas 4), M.V. Yamada leg. (MZUSP). Paratypes: 3 males, same as holotype. 2 males, São Catarina State, Florianópolis, Unidade de Conservação Ambiental Desterro (U.C.A.D.), 03-20.xi.2003, Malaise trap, near stream, L.C. Pinho leg. 1 male, São Paulo State, Salesópolis, Estação Biológica Boracéia, Trilha dos Pilões, 23° 39’ 01.9” S and 45° 53’ 36” W, 30.iii-02.iv.2001, Malaise trap (Mata 1), S.T.P. Amarante et al. leg. (BIOTA-FAPESP BORA09). 2 males, same as previous except for 23° 39’ 03” S and 45° 53’ 36” W, 02-05.iv.2001, Malaise trap (Bosque 1), (BIOTA-FAPESP BORA06). 1 male, same as previous except for 23° 39’ 06.3” S and 45° 53’ 48.9” W, Malaise trap (Mata 1) (BIOTA-FAPESP BORA15). 1 male, São Paulo State, Parque Estadual Intervales, Ribeirão Grande, Barra Grande, 24° 15’ 5” S and 48° 10’ 10” W, 10-13.xii.2000, Malaise trap (Bosque 4), M.T. Tavares et al. leg. (BIOTA-FAPESP PEIN03). 1 male, same as previous except for 13-16.xi.2000, Malaise trap (Trilha 5), (BIOTA-FAPESP PEIN09). 1 male, same as previous except for Malaise trap (Trilha 1), (BIOTA-FAPESP PEIN10). 2 males, São Paulo State, Parque Estadual Serra do Mar, Ubatuba, 23° 21’ 43” S and 44° 59’ 22” W, 24.1.2002, Malaise trap (Trilha 5), N.W. Perioto et al. leg. (BIOTA-FAPESP BRUB14). 1 male, same as previous except for Malaise trap (Trilha 1), (BIOTA-FAPESP BRUB17). 1 male, same as previous except for 21.12.2002 Malaise trap (Bosque 9), (BIOTA-FAPESP BRUB13).

Description: Male (n = 8-10, except when otherwise stated). Total length 1.24-1.46, 1.35 mm. Wing length 709-939, 835 µm. Total length/wing length 1.51-1.75, 1.60. Wing length/length of profemur 2.56-3.00, 2.82.

Coloration. Thorax, head, and pedicel dark brown; abdomen, legs, and antennal flagellum slightly lighter brown; wings translucent.

Etymology: The species is named after Max Rieber-Mohn, see etymology for genus name.

Acknowledgements

We are indebted to Dr. Carlos J. E. Lamas, Museu de Zoologia, Universidade de São Paulo and to Dr. Dulan S. Amorim, Faculdade de Filosofia Ciências e Letras de Ribeirão Preto, Universidade de São Paulo campus Ribeirão Preto for the loan of specimens from the BIOTA–FAPEP project (“Limites geográficos e fatores causais de endemismo na Floresta Atlântica em Diptera” proc. 03/12074–9 within The Biodiversity Virtual Institute Program (www.biota.org)). Thanks are also due to Dr. Luiz C. Pinho, Universidade Federal de Santa Catarina for making the material collected in Santa Catarina available to us. Gladys Ramirez made the slide preparations. The study was partially funded by FAPEP (11/50162-1), partially by the University Museum of Bergen.
