DOI: [https://doi.org/10.22271/chemi.2020.v8.i2j.8838](https://doi.org/10.22271/chemi.2020.v8.i2j.8838)

Abstract

To assess seasonal variations in trace metals contents in oyster *Crassostrea gasar*, samples were collected from six selected stations in Milliardaires Bay (Côte d’Ivoire) in the dry, flood and rainy seasons. Lead (Pb), cadmium (Cd), nickel (Ni), manganese (Mn) and zinc (Zn) concentrations were determined in the soft tissues by flame atomic absorption spectroscopy. Average (±standard deviation) concentrations of Pb, Cd, Ni, Mn, and Zn ranged from 40.06±124.77 to 301.91±216.27, 1.44±0.87 to 2.29±1.64, 23.86±18.46 to 172.32±518.55, 25.96±19.41 to 55.00±63.20 and 2332.99±2096.71 μg/g dry weight respectively. According to the two-way ANOVA analysis of variance, seasonal variations of Pb, Ni, and Zn were statistically significant (p<0.0001), at the opposite of Cd (p=0.9977) and Mn (p=0.7780) ones. Pb exhibited highest contents in the dry season, while those of Cd and Zn recorded in the flood and rainy ones. The seasonal variations of Ni and Zn were found dependent on the individual location each sampling station. The concentrations of the toxic metals (Pb and Cd) were of particular concern, calling efforts to address the contamination problem in Milliardaires Bay.

Keywords: Bioaccumulation, trace metals, toxicity, oyster, *Crassostrea gasar*, seasonal variation, Milliardaires Bay, Côte d’Ivoire

Introduction

Trace metals are among pollutants that can have hazardous effects on marine organisms and human as consumers. If metals leached from soil and rocks to aquatic systems are known to be naturally ubiquitous and pose minimal threats to the environment and human health (Páez-Osuna and Osuna-Martínez, 2015) [19], those of several anthropogenic sources (domestic, agriculture, aquaculture, harbor and mining) increase metal burdens exceeding natural levels (Góngora-Gómez et al., 2017) [6]. Alterations of enzyme activities such as alkaline phosphatase, abnormal development of fetus, procreation failure, and immunodeficiency are among harmful effects due to aquatic metal exposure (Zhou et al., 2008) [30]. Bivalves, as sessile organisms that can accumulate and exhibit efficient strategies to deal with the potential toxic effect of metals (Arifin and Bendell-Young, 1997) [1] and their abundance and wide distribution, they are widely utilized as biomarkers for monitoring metal contamination in aquatic systems (Kanthai et al., 2014) [10]. Since oysters are sedentary and filter feeders, they are susceptible to metal accumulation and, therefore, are ideal sentinel organisms for assessing environmental pollution along tropical and subtropical coasts (Páez-Osuna et al., 1995) [16]. Further, this bivalve can be a vector of toxic chemicals such as trace metals for humans as its consumers. Since the 1980s, several species of the genus *Crassostrea* have been studied worldwide in relation to metal contamination such as *Crassostrea commercialis* in the Gulf of Thailand (Phillips and Muttarasin, 1985) [19], *Crassostrea angulata* on the Spanish south Atlantic shore (Lopez-Artiguez et al., 1989) [12] and *Crassostrea corteziensis* on the northwest coast of Mexico (Páez-Osuna and Marmolejo-Rivas, 1990) [17], *Crassostrea gasar* on a lagoon of Togo (Ouro-Sama et al., 2014) [15], *Crassostrea gasar* of Côte d’Ivoire (Metongo et al., 1991; Tuo et al., 2019) [13, 25]. Seasonal variations of metals bioaccumulation in marine organisms are also studied worldwide (Prabal et al., 2011; Weng and Wang, 2019) [20, 27]. In Côte d’Ivoire, the oyster *Crassostrea gasar* is widely present in several coastal areas.
Previous studies conducted in Milliardaires Bay have revealed a seasonal variation in nutrients, metals and organic matter concentrations in waters and sediments (Tuo et al., 2012; Tuo et al., 2013; Bakary et al., 2014; Tuo et al., 2015)\cite{22, 23, 2, 24} and high levels of metals in bivalves such as *Anadara senilis* with seasonal variations (Bakary et al., 2015)\cite{3} and *Crassostrea gasar* (Metongo et al., 1991; Tuo et al., 2015)\cite{13} in relation with an increase in anthropogenic activities around the Ebrié Lagoon including the Milliardaires Bay, thus indicating a potential risk for human health. Tuo et al., (2019)\cite{25} have reported high concentrations of Pb in *C. gasar* inhabiting Milliardaires Bay, with high values of bioconcentration factors (BCF), thus confirming its abilities in metal bioaccumulation. Other studies were conducted to assess population dynamics (Yapi et al., 2017)\cite{28}, reproduction cycle (Yapi et al., 2018)\cite{29} and histological study of sex annual cycle of *C. gasar* from Ebrié and Aby Lagoons (Kouakou et al., 2018)\cite{11}. If there are a few studies regarding metals concentrations in oysters from Ebrié Lagoon (Metongo et al., 1991; Tuo et al., 2019)\cite{13, 25}, there are no data in relation with the seasonal variations of trace metals contents in the tissues of the oyster *Crassostrea gasar* inhabiting the Ebrié lagoon. The present paper presents a study on seasonal variation of trace metals (Pb, Cd, Ni, Mn and Zn) concentrations in the soft tissues of the oyster *C. gasar* collected from six locations along the Milliardaires Bay in the dry, rainy and flood seasons.

**Materials and Methods**

**Study area:** Oysters were collected in Milliardaires Bay, located in the Ebrié Lagoon of Côte d’Ivoire (Fig. 1). The Milliardaires Bay (4°19’-4°27’W; 5°8’-5°10’N) is located at approximately 50 km from Abidjan Harbor (Bakary et al., 2015)\cite{3}. The climate is of sub-equatorial with three distinguish lagoon seasons including a Dry Season (December- March), a rainy season (April- August) and a flood season (September-November). These three seasons influence the lagoon chemistry due to nature and levels of waters that dilute the lagoon ones. Indeed, dilution waters are from marine origin in the dry season, while they are of continental origin in the rainy and flood seasons (Tuo et al., 2012)\cite{22}.

**Collection of samples:** For this study, 360 oysters were randomly collected from about 10 m² and were found in a size range 4-12 cm shell length in Milliardaires Bay from February 2008 to December 2009, from six selected stations (Fig. 1). All sampling and laboratory equipment were previously washed with detergent, rinsed with distilled water, soaked in 5% nitric acid, rinsed with distilled water (and oven-dried if necessary) to ensure any trace of cleaning reagent were removed before the sampling and/or samples preparation and analysis. Finally, they were dried at room temperature (25 °C) and store in a clean place. At the laboratory, oysters were washed and rinsed with distilled water to move out all particles (such as organic matters) from sediments accumulated on different shells. Then, oysters were analyzed for metal contents.

**Analysis of samples:** The whole soft tissues of each oyster was move off it shell and collected into Pyrex beakers, and oven-dried at 105 °C overnight until constant weight. Each dried sample was then homogenized using pestle and mortar and the homogenized powder was stored in polyethylene bag. Two replicates of approximately 0.3 g of each homogenized powder were weighed into boiling tubes and 10 mL of concentrated analytical grade nitric acid was added to each sample and left to pre-digest overnight at room temperature in a fume hood. Reagent blanks were processed simultaneously. Then, the boiling tubes were placed on a heating block to reflux at 130 °C for 6 hours. After cooling, the digests were diluted with 5 mL of deionized water into 25 mL volumetric flasks. Each solution was made up to volume with deionized water rinses of the residues. The prepared solutions were
analyzed for lead, cadmium, nickel, manganese and zinc, by flame atomic absorption spectroscopy (A Perkin, model 3030), with deuterium continuum background correction. The results of samples analyses were submitted to statistical analyses.

**Statistical analysis:** Microsoft Excel 2007 was used to calculate the mean seasonal concentrations and to draw graphs, while the correlation matrix and the two-way ANOVA analysis were performed with STATISTICA Software (2005, 7.1 Version). Data collected were subjected to the two-way ANOVA analysis of variance to assess whether metal contents in samples varied significantly between locations and seasons, possibilities less than 0.05 ($p < 0.05$) were be considered statistically significant.

**Results**

Table 1 presents the results of trace metal concentrations (in μg/g dry weight) observed in the tissues of oyster *Crassostrea gasar* collected in Milliardaires Bay in the different seasons and some permissible limits recommended for sea food. The spatial and seasonal of metal concentrations are shown in Fig. 2. The results relative of the two-way ANOVA analysis of variance regarding trace metals in the tissues of *C. gasar* and the results of Pearson correlation analysis are respectively presented in tables 2 and 3. Means and standard deviations of seasonal concentrations of Pb, Cd, Ni, Mn and Zn were found in respective ranges of 40.06±124.77 to 301.91±216.27, 1.44±0.87 to 2.29±1.64, 23.86±18.42 to 172.32±518.55, 25.96±19.41 to 55.00±63.20 and 2537.34±1537.78 to 3322.99±2096.71 μg/g dry weight (Table 1). The metal accumulation in the tissues of oyster *C. gasar* were in the decreasing order of Zn > Pb > Ni > Mn > Cd.

![Graph](a)

**Table 1:** Averages and standard deviations (in μg/g dry weight) of trace metal observed in *Crassostrea gasar* collected from Milliardaires Bay in different stations.

| Seasons     | Concentration of trace metal in oyster *C. gasar* (μg/g dry weight) |
|-------------|---------------------------------------------------------------------|
|             | Pb                     | Cd                     | Ni                     | Mn                     | Zn                     |
| Dry season  | 289.55±181.49          | 2.17±0.96              | 23.86±18.42            | 25.96±19.41            | 3322.99±2096.71        |
| Rainy season| 301.91±216.27          | 1.44±0.87              | 32.13±37.64            | 33.19±23.45            | 2537.34±1537.78        |
| Flood season| 40.06±124.77           | 2.29±1.64              | 172.32±518.55          | 55.00±63.20            | 3188.35±1587.45        |

SSSA (1993) [21]; ISCC (2007) [8]; FDA (1993) [5]

Regarding individual stations, seasonal concentrations of Pb ranged from 6.6 to 958.8 μg/g (Fig. 2a). In the dry season, the lowest mean concentration (312.3 μg/g) was observed in ST3. For the rainy season, the lowest and highest contents were respectively observed in ST3 (90.91 μg/g) and ST6 (184.87 μg/g). In the dry season, station ST4 recorded the lowest mean concentration of Pb (6.6 μg/g) while ST2 exhibited the highest one with a value of 958.8 μg/g. Apart from ST2, Pb levels were found in the following seasonal ascending rank: dry season > rainy season > flood season (Fig. 2a). The two-way ANOVA analysis of variance showed statistically significant differences ($p<0.0001$) between the sampling stations in one hand and, on the over hand, between the three seasons (Table 2). Pb contents observed in *C. gasar* were significantly correlated to the shell lengths ($r=0.99$) and wet weights ($r=1.00$) (Table 3). Fig. 2b presents the seasonal variations of Cd in the different locations. In the dry season, Cd wasn’t detected in samples collected in stations ST3, ST4 and ST6 because of values very below the detection limit of the technique used, respective values of 0.6, 0.75 and 0.91 μg/g were observed in stations ST1, ST2 and ST5. For the rainy season, Cd concentrations ranged from 0.58 (ST4) to 2.41 μg/g (ST3). The lowest and highest mean concentrations of Cd were respectively observed in ST2 (1.4 μg/g) and ST6 (3.06 μg/g) in the flood season (Fig. 2b). Apart from ST3 for which Cd level observed in the rainy season was found higher than the flood one, the seasonal rank of Cd was the opposite of the Pb one as follows: dry season < rainy season < flood season (Fig. 2b).
Cd exhibited statistically significant differences \((p<0.0001)\) between the locations (Table 2). For the seasonal variation in Cd contents, according to the result \((p=0.9977>0.05)\) of the two-way ANOVA analysis, no significant difference was observed between the three seasons. Cd exhibited positive and statistically significant correlation between Cd contents in *Crassostrea gasar* with the shell lengths \((r=1.00)\) and the wet weights \((r=0.99)\) of the organisms (Table 3). Statistically significant positive correlation was observed between Cd contents and those of Mn \((r=0.69)\), while a statistically significant inverse correlation \((r=-0.77)\) was observed between Cd and Zn contents in the oysters (Table 3). The seasonal contents of Ni in *C. gasar* ranged from 14.03 to 136.39 μg/g (Fig. 2c). Regarding spatial trends, Ni contents observed in the oysters were in the following ranges of 14.03-62.7, 27.2-136.39 and 38.8-296.0 μg/g, respectively in the dry, rainy and flood seasons (Fig. 2c). Ni exhibited the general following seasonal rank: Flood season>Rainy season>Dry season. Two-way ANOVA analysis of variance showed statistically significant differences between locations \((p<0.0001)\) and seasons \((p=0.0002)\) (Table 2). Significant correlation was observed between Ni levels \((r=0.69)\) and those of Mn in the tissues of *C. gasar*.

**Fig 2:** Seasonal variations of lead (a), cadmium (b), nickel (c), manganese (d) and zinc (e) in the soft tissues of *Crassostrea gasar* from selected stations in Milliardaires Bay.

| Zn                 | -0.77*       | -0.79*     | 0.20 | -0.77*| -0.08| -0.46| 1.00 |

*: Significant correlation at \(p<0.05\).
Regarding the selected stations, seasonal mean values of Mn in oysters ranged from 2.83 to 89.93 μg/g. The same range was observed in the dry season (Fig. 2d). For the dry season, Mn was not detected in samples collected in stations ST5 and ST6 (Fig. 2d). Respective concentrations ranges of 42.12 to 51.74 μg/g and 33.54 to 69.06 μg/g were observed in the rainy and flood seasons. For present study, Mn concentrations were in the following decreasing seasonal rank: Flood season>Rainy season>Dry season (Fig. 2d). While sampling locations of oysters were found significantly different (p<0.0001), no significant differences was observed between the studied seasons (p=0.7780) (Table 2). Significant positive correlations were observed between Mn levels and the shell lengths (r=0.68) and the wet weights (r=0.64) of the animals (Table 3). Significant positive correlations were also observed between Mn and Cd (r=0.69) and also between the concentrations of Mn and those of Ni (r=0.68) (Table 3). Fig. 2e presents the seasonal trends of Zn contents in C. gasar. Seasonal mean concentrations of Zn ranged from 17.6 to 4017 μg/g. Respective ranges of 17.6-3358; 1047.49-2693.78 and 37.46-4017 μg/g were observed in the dry, rainy and flood seasons for Zn contents (Fig. 2e). Zn exhibited the following seasonal descending rank: Rainy season<Flood season<Dry season (Fig. 2e). Statistically significant inverse correlations were observed between Zn and shell lengths (r=0.77) and wet weights (r=0.79) (Table 3). Significant inverse correlations Zn/Cd (r=-0.77) and Zn/Mn (r=0.46) were also observed (Table 3).

**Discussion**

Pb exhibited concentrations in all the three seasons higher than the recommended values for FAO/WHO (1992) as 0.05 μg/g, US-FDA (2003) as 1.7 μg/g. SSSA (1993) as 1.0 μg/g. Apart from Cd which exhibited contents higher than the recommended limit in the flood season (ISCC, 2007) in oysters collected in station ST6 which recorded a level of 3.06 μg/g, levels observed for Ni, Mn and Zn were lower or within the permissible limits for sea food (Table 1, (Fig. 2). Pb contents observed in C. gasar inhabiting the Milliardaires Bay were higher than the levels (0.004-0.02 mg/g d.w) reported by Onwuteaka et al. (2015) [14] for the same organism from water creek of the NIGER Delta (Nigeria). Excessive concentrations of toxic metals like Pb and Cd in the tissues and organs of marine organisms may adversely affect cellular functions by interacting with systemic enzymes and can also lead to dysfunction of the endocrine system, immune system, metabolism, reproduction and growth (Hylland, 2006) [7]. Considering high concentrations of Pb observed in the present work, oysters inhabiting the Milliardaires Bay were found unsafe for human consumption (Table 1). Cd levels observed in the present study were generally lower than the permissible limit of 0.5 μg/g wet weight (ISCC (2007) [8] and those (0.001-0.05 mg/g) found in C. gasar from water creek of the NIGER Delta (Nigeria) (Onwuteaka et al., 2015) [14]. According to our data, in oyster C. gasar, a small part of Zn can be substituted by the Cd, a toxic metal even at low levels (Table 3). Levels of Ni observed in C. gasar from Milliardaires Bay were lower than the permissible limit (FDA, 1993) [5], and higher than those found in C. gasar from water creek of the NIGER Delta (Nigeria) (Onwuteaka et al., 2015) [14]. Levels of Zn observed in the present study were in the same range with those reported by Metongo (1991) [13] for the same oyster C. gasar collected in several areas in the Ebrié Lagoon. Zn, as a constituent of haemocyanin in molluscs and its major importance in metabolic processes by ensuring the proper functioning of many enzymes, occur in higher levels in the tissues of bivalves such as oysters (Jakimak et al., 2011) [9]. The statistically significant spatial variations in the contents of the five metals (Pb, Cd, Ni, Mn and Zn) are in agreement with the spatial variations in physicochemical parameters, nutrients, metals and/ or organic matter observed in waters and/or sediments collected in the same Milliardaires Bay (Tuo et al., 2012; Tuo et al., 2013; Bakary et al., 2014; Tuo et al., 2015) [22, 23, 24]. Bakary et al. (2015) [9] did not observed significant difference in metals accumulation in A. senilis living in the same area, indicating a difference in metal accumulation for the two bivalve’s species. The differences between the studied seasons were statistically significant (p<0.0001) for Pb, Ni and Zn, at the opposite of Cd and Mn with no significant differences between seasons regarding metal concentrations (Table 2). In the same Milliardaires Bay, Bakary et al. (2015) [9] have reported significant seasonal variations in total concentrations of Zn, Cu, Cd and Pb in A. senilis between the dry and rainy seasons. Indeed, trace metals bioaccumulation in marine animals including oysters depend on their levels in the surrounding waters and sediments that are also their feeding sources. The uptake, fate, effects of contaminants, gender, age, body size, nutrition, reproductive status, environmental factors (pH, temperature, salinity, dissolved oxygen, etc.), metal bioavailability, etc. are among factors that can influence the bioaccumulation of pollutants like metals in marine organisms (Zhou et al., 2008) [10]. Statistically significant positive correlations observed between the Cd (and Mn) with shell lengths and wet weights indicated an increase in selected metals contents in the tissues of the organisms along their life. At the opposite of Cd and Mn, statistically significant inverse correlations were observed between Zn contents and shell lengths, wet weights and Cd contents, due to the fact that Zn is an essential metal for oysters on one hand, and on the other hand in relation with a possible competition between Zn and Cd. A moderate inverse correlation was also observed between Mn and Pb (Mn/Pb, r=-0.43), as a result of a competition between the two metals. Positive relationship were observed between Mn, Cd and Ni as the result of interactions among these metals within the oysters, in terms of competition for binding locations on specific enzymes or receptors during the processes of absorption, excretion, sequestration, or as a target site. Páez-Osuna and Mamolejo, (1990) [17] have also reported positive correlation between Pb, Cd, Ni and Co in Crassostrea corteziensis and in ambient marine system. The substitution of essential metals (Mn and Zn) with non-essential ones (Cd and Pb) can lead to an increase of hazardous effects on oysters and, finally on humans.

**Conclusion**

Seasonal variations of the studied trace metals in oyster Crassostrea gasar were found significant for Pb, Ni, and Zn, except for Cd and Mn which also recorded highest concentrations in the flood and rainy seasons. Pb concentrations observed in the dry season were higher than those of the wet (flood and rainy) ones in all the sampling stations. For Ni and Zn, the seasonal variations were very dependent on the location of the selected sampling stations. Pb levels were higher than the permissible limit, indicating that oysters from Milliardaires Bay were unsafe for human consumption. However, Pb levels observed in the flood season were seven times lower than those of the other seasons. Overall, the present study provided baseline
information on the seasonal variations of the concentrations of Pb, Cd, Ni, Mn and Zn in Crassostrea gasar inhabiting the Milliardaires Bay which may be needed for further studies. In addition, anthropogenic activities have to be reduced around the Milliardaires Bay to avoid its contamination in pollutants such as trace metals, for the protection of the biodiversity.
