Abstract
In this work we prove that each $C^r$ conservative diffeomorphism with a pair of hyperbolic periodic points of co-index one can be $C^1$-approximated by $C^r$ conservative diffeomorphisms having a blender.

Mathematics Subject Classification: 37C40; 37C20; 37D30

1. Introduction

One major task in the theory of dynamics is to establish some kind of dynamic irreducibility of a system. Of principal interest are the systems that display some kind of persistent irreducibility. The two main examples of this concept are robust transitivity and stable ergodicity.

Blenders were introduced by Bonatti and Díaz in [5], to produce a large class of examples of non-hyperbolic robustly transitive diffeomorphisms. There, they showed that these objects appeared in a neighbourhood of the time-one map of any transitive Anosov flow. These systems are partially hyperbolic. To establish robust transitivity, they showed that the strong invariant manifolds entered a small ball (the blender), where things got mixed. This blending was then distributed all over the manifold by means of the strong invariant manifolds. This phenomenon is robust, whence they get robust transitivity.

In [6], Bonatti and Díaz showed that blenders appear near co-index one heterodimensional cycles. This provides a local source of robust transitivity.

In [13, theorem C], the authors showed that, surprisingly, blenders also provide a local source of stable ergodicity, see also [12]. This arouses some interest in the appearance of blenders in the conservative setting. Indeed, the presence of blenders near pairs of periodic points of co-index one in the conservative setting allows the authors to prove a special case of a longstanding conjecture by Pugh and Shub, namely that stable ergodicity is $C^1$-dense among partially hyperbolic diffeomorphisms with two-dimensional centre bundle [12, 13].
The aim of this paper is to obtain conservative diffeomorphisms admitting blenders near conservative diffeomorphisms with a pair of hyperbolic periodic points with co-index one. This result is crucial in the proof of the Pugh–Shub conjecture [13]. Let us note that, in fact, what we need for the proof of the Pugh–Shub conjecture is a very special case of theorem 1.1. We think that in view of the new importance of blenders for the conservative setting, it is interesting to state the result in its full generality.

The main result of this paper is the following theorem.

**Theorem 1.1.** Let \( f \) be a \( C^r \) diffeomorphism preserving a smooth measure \( m \) such that \( f \) has two hyperbolic periodic points \( p \) of index \( u + 1 \) and \( q \) of index \( u \). Then there are \( C^r \) diffeomorphisms arbitrarily \( C^1 \)-close to \( f \) which preserve \( m \) and admit a \( cu \)-blender associated with the analytic continuation of \( p \).

The proof of theorem 1.1 closely follows the scheme in [6].

2. Sketch of the proof

All preliminary concepts are in section 3. Let \( f \) be a \( C^r \) diffeomorphism preserving a smooth measure \( m \) such that \( f \) has two hyperbolic periodic points \( p \) of index \( u + 1 \) and \( q \) of index \( u \). A first step is to prove the following proposition.

**Proposition 2.1.** Let \( f \) be a \( C^r \) conservative diffeomorphism such that \( f \) has two hyperbolic periodic points \( p \) of index \( u + 1 \) and \( q \) of index \( u \), then \( C^1 \)-close to \( f \) there is a \( C^r \) conservative diffeomorphism such that the analytic continuations of \( p \) and \( q \) form a co-index one heterodimensional cycle.

The proof of this involves a combination of recurrence results by Bonatti and Crovisier, the connecting lemma, and a recent result by Ávila concerning approximation of conservative \( C^1 \) diffeomorphisms by smooth conservative diffeomorphisms. We prove this proposition in section 4.

The goal of the rest of the paper is to reduce this heterodimensional cycle to a standard form, in which perturbations are easily made. Note that in a co-index one heterodimensional cycle associated with the points \( p \) and \( q \) with periods \( \pi(p) \) and \( \pi(q) \), both \( Df^{\pi(p)}(p) \) and \( Df^{\pi(q)}(q) \) have \( s \) contracting eigenvalues and \( u \) expanding eigenvalues. There is a remaining (central) eigenvalue which is expanding for \( Df^{\pi(p)}(p) \) and contracting for \( Df^{\pi(q)}(q) \). This centre eigenvalue, however, could be complex or have multiplicity bigger than one. This could complicate getting a simplified model of the cycle. The next step is to show, as in [6], the following theorem.

**Theorem 2.2.** Let \( f \) be a \( C^r \) conservative diffeomorphism having a co-index one cycle associated with the periodic points \( p \) and \( q \). Then \( f \) can be \( C^1 \)-approximated by \( C^r \) conservative diffeomorphisms having co-index one cycles with real central eigenvalues associated with the periodic points \( p' \) and \( q' \) which are homoclinically related to the analytic continuation of \( p \) and \( q \).

The fact that \( p' \) and \( q' \) are homoclinically related to the analytic continuation of \( p \) and \( q \) is important due to the fact that if \( Bl^u(p) \) is a \( cu \)-blender associated with \( p \) and \( p' \) is homoclinically related to \( p \) then \( Bl^u(p) \) is also a \( cu \)-blender associated with \( p' \). See remark 3.4. The proof of theorem 2.2 is in section 4.

The proof of theorem 1.1 shall now follow after proving theorems 2.3 and 2.4.
**Theorem 2.3.** Let $f$ be a $C^r$ conservative diffeomorphism having a co-index one cycle with real central eigenvalues. Then $f$ can be $C^1$-approximated by $C^r$ conservative diffeomorphisms having strong homoclinic intersections associated with a hyperbolic periodic point with expanding real central eigenvalue.

Theorem 2.3 is the more delicate part. The next theorem is now standard after Bonatti, Díaz and Viana’s work [9].

**Theorem 2.4.** Let $f$ be a $C^r$ diffeomorphism preserving $m$ with a strong homoclinic intersection associated with a hyperbolic periodic point $p$ with expanding real centre eigenvalue. Then $f$ can be $C^1$-approximated by a $C^r$ diffeomorphism preserving $m$ and having a cu-blender associated with $p$.

In the creation of conservative blenders, we closely follow the scheme in [6]. It will be proved that after a $C^1$-perturbation, we obtain a $C^r$ conservative diffeomorphism such that the co-index one cycle with real central eigenvalue has local coordinates where the dynamics of the cycle is affine and partially hyperbolic, with one-dimensional central direction. This is called a simple cycle, see definition 3.8. Let us note that, unlike in [6], we cannot use Sternberg’s theorem to linearize, due to the obvious resonance. We use instead the pasting lemmas by Arbieto and Matheus [1]. The construction of simple cycles $C^1$-close co-index one cycles with real centre eigenvalues is proved in section 5.

We shall afterwards produce a continuous family of perturbations $\{f_t\}_{t>0}$ of $f$ shifting the unstable manifold of $q$ in a linearized neighbourhood of $p$ so that it does not intersect $W^u(p)$, thus breaking the cycle. These perturbations preserve the bundles $E^s$, $E^c$ and $E^u$. In this form, they induce maps of the interval on $E^c$. By carefully choosing a small parameter $t > 0$, and possibly ‘touching’ the centre expansion/contraction, we may obtain that there is an $E^s \oplus E^u$ plane that is periodic by two different itineraries of $f_t$. Now, the dynamics $f_t$ on this periodic plane is hyperbolic, using a Markovian property, we get two periodic points that are homoclinically related within this plane. Using the $\lambda$-lemma we obtain a periodic point with a strong homoclinic intersection. This is done in section 6.

In this way we can apply the well-known techniques of Bonatti, Díaz and Viana [9] and of Bonatti, Díaz which give blenders near points with strong homoclinic intersections [5]. Note that these perturbations can be trivially made so that the resulting diffeomorphism be $C^r$ and conservative.

### 3. Preliminaries

From now on, we shall consider a smooth measure $m$ on a smooth manifold $M$, and a $C^r$ diffeomorphism $f : M \to M$ preserving $m$.

#### 3.1. Definitions

We shall say that $f$ is **conservative** if $f$ preserves $m$. Given a hyperbolic periodic point $p$ of $f$, the **index** of $p$ is the number of expanding eigenvalues of $Df^{\pi(p)}(p)$, counted with multiplicity, where $\pi(p)$ is the period of $p$.

**Definition 3.1 (Heterodimensional cycle).** A diffeomorphism $f$ has a heterodimensional cycle associated with two hyperbolic periodic points $p$ and $q$ of $f$ if their indices are different, and the stable manifold $W^s(p)$ of $p$ meets the unstable manifold $W^u(q)$ of $q$, and the unstable manifold $W^u(p)$ of $p$ meets the stable manifold $W^s(q)$ of $q$. 
Figure 1. cu-blender associated with p.

When the indices of p and q differ in one, we say p and q are a co-index one heterodimensional cycle or co-index one cycle.

We shall say that \( f \) is partially hyperbolic on an \( f \)-invariant set \( \Lambda \), or \( \Lambda \) is partially hyperbolic for \( f \) if there is a \( Df \)-invariant splitting \( T_\Lambda = E^s_\Lambda \oplus E^c_\Lambda \oplus E^u_\Lambda \) such that for all \( x \in \Lambda \) and all unit vectors \( v^\sigma \in E^\sigma, \sigma = s, c, u \) we have

\[
\|Df(x)v^s\| < \|Df(x)v^c\| < \|Df(x)v^u\|
\]

for some suitable Riemannian metric on \( M \). We require that both \( E^s \) and \( E^u \) be non-trivial.

Our goal is to produce a \( C^1 \)-perturbation admitting a blender. Here is the definition of blender we shall be using:

**Definition 3.2 (cu-blender near p).** Let \( p \) be a partially hyperbolic periodic point for \( f \) such that \( Df \) is expanding on \( E^c \) and \( \dim E^c = 1 \). A small open set \( \text{Bl}^{cu}(p) \), near \( p \) but not necessarily containing \( p \), is a cu-blender associated with \( p \) if:

1. every \((u+1)\)-strip well placed in \( \text{Bl}^{cu}(p) \) transversely intersects \( W^s(p) \).
2. This property is \( C^1 \)-robust. Moreover, the open set associated with the periodic point contains a uniformly sized ball.

A \((u+1)\)-strip is any \((u+1)\)-disc containing a \( u \)-disc \( D^u \), so that \( D^u \) is centred at a point in \( \text{Bl}^{cu}(p) \), the radius of \( D^u \) is much bigger than the radius of \( \text{Bl}^{cu}(p) \), and \( D^u \) is almost tangent to \( E^u \), i.e. the vectors tangent to \( D^u \) are \( C^1 \)-close to \( E^u \). A \((u+1)\)-strip is well placed in \( \text{Bl}^{cu}(p) \) if it is almost tangent to \( E^c \oplus E^u \). See figure 1.

Naturally, it makes sense to talk about robustness of these properties and concepts, since there is an analytic continuation of the periodic point \( p \) and of the bundles \( E^s, E^c \) and \( E^u \). We can define cs-blenders in a similar way. For cs-blenders we will consider a partially hyperbolic point such that \( E^c \) is one dimensional and \( Df \) is contracting on \( E^c \).

This is the definition of blender we shall be using in this work, and, in particular what we obtain in theorem 1.1. We warn the reader that there are other definitions of blenders. In [10, chapter 6.2], there is a complete presentation on the different ways of defining these objects. Our definition corresponds to definition 6.11 of [10] (the operational viewpoint). In some works of Bonatti and Díaz, see for instance [5, 6], what we call \( \text{Bl}^{cu}(p) \) is known as the characteristic region of the blender; and what they call blender is in fact a hyperbolic set which is the maximal invariant set of a small neighbourhood of \( q \) (definition 6.9 of [10]). However, let us note that, under the hypothesis of theorem 1.1, we obtain a \( C^1 \)-perturbation preserving \( m \) and admitting blenders also in the sense of definition 6.9 of [10], and of [9]. The existence of blenders in the sense of [9] implies the existence of blenders in the sense of definition 3.2.
Definition 3.3 (cu-blender associated with \( p' \)). Let \( p' \) be a partially hyperbolic periodic point for \( f \) such that \( Df \) is expanding on \( E' \), with \( \dim E' = 1 \). A small open set \( B \) is called cu-blender associated with \( p' \) if \( B = \text{Bl}^{cu}(p) \), where \( p \) is a partially hyperbolic periodic point homoclinically related to \( p \) and \( \text{Bl}^{cu}(p) \) is a cu-blender near \( p \). We shall also denote \( \text{Bl}^{cu}(p') \) the cu-blender associated with \( p' \).

Remark 3.4. Let us note that if \( \text{Bl}^{cu}(p') \) is a cu-blender associated with a hyperbolic periodic point \( p' \) and \( \text{Bl}^{cu}(p) \) is a cu-blender near \( p \), where \( p \) is homoclinically related to \( p' \), then it follows from the \( \lambda \)-lemma that \( W'(p') \) transversely intersects every \((u+1)\)-strip well placed in \( \text{Bl}^{cu}(p) \), and that this property is robust. The \( \lambda \)-lemma also implies that a cu-blender associated with \( p' \) is also a cu-blender associated with \( p'' \) if \( p' \) and \( p'' \) are homoclinically related.

Remark 3.5. If \( f \) is a partially hyperbolic diffeomorphism in \( M \), then we can define cu-blender associated with a periodic point \( p' \) directly as in definition 3.2, without requiring that \( \text{Bl}^{cu}(p') \) be near \( p' \). Indeed, this requirement is only needed to guarantee the existence of the \((u+1)\)-strips well placed in \( \text{Bl}^{cu}(p') \). In the case that \( f \) is partially hyperbolic, the \( E' \) and \( E^c \) bundles are globally defined, and so definition 3.2 makes sense even without asking that \( \text{Bl}^{cu}(p') \) be near \( p' \).

Let us consider two hyperbolic periodic points \( p \) of index \((u+1)\) and \( q \) of index \( u \), with periods \( \pi(p) \) and \( \pi(q) \), respectively. Let us denote by \( \lambda^s_i(p) \), \( \lambda^u_i(p) \) the eigenvalues of \( Df^{\pi(p)}(p) \) and \( Df^{\pi(q)}(q) \), respectively, with \( i = s, c, u \), ordered in such a way that

\[
|\lambda^s_1(x)| \leq \cdots \leq |\lambda^s_k(x)| \leq |\lambda^c_1(x)| \leq \cdots \leq |\lambda^u_k(x)|, \tag{3.1}
\]

where the \( \lambda^s_i \) are contracting and the \( \lambda^c_i \) are expanding. Moreover, \( \lambda^c(x) \) is expanding for \( p \) and contracting for \( q \). Note that \( \lambda^c(x) \) could be equal to \( \lambda^u_i(x) \), and could be a complex eigenvalue.

Definition 3.6 (Cycle with real central eigenvalues). A co-index one heterodimensional cycle associated with two hyperbolic periodic points \( p \) and \( q \) as described above has real central eigenvalues if \( |\lambda^c(p)| < |\lambda^u_i(p)| \) and \( |\lambda^c(q)| < |\lambda^s_i(q)| \).

Note that when a cycle has real central eigenvalues, then \( \lambda^c(p) \) and \( \lambda^c(q) \) have multiplicity one. In the rest of this subsection, we shall work with heterodimensional cycles with real central eigenvalues. In this case, both orbits of \( p \) and \( q \) admit a partially hyperbolic splitting \( TM = E^s \oplus E^c \oplus E^u \), with \( \dim E^c = 1 \), \( \dim E^s = s \) and \( \dim E^u = u \). We shall denote \( W^{ss}(p) \) the strong stable manifold of \( p \); this means, the invariant manifold tangent to \( E^s_p \) that has dimension \( s \). Analogously we define \( W^{uu}(p) \), the strong unstable manifold of \( p \). Note that the unstable manifold of \( p \) could be of dimension \((u+1)\), in which case it would contain \( W^{uu}(p) \).

Definition 3.7 (Strong homoclinic intersection). A partially hyperbolic periodic point \( p \) has a strong homoclinic intersection if

\[
\{p\} \not\subset W^{ss}(p) \cap W^{uu}(p).
\]

The first goal is to obtain a \( C^1 \)-perturbation of \( f \) admitting a co-index one cycle with some local coordinates such that the dynamics in a neighbourhood of the points are affine.

Definition 3.8 (Simple cycle). A co-index one cycle associated with the periodic points \( p \) of index \((u+1)\) and \( q \) of index \( u \) is called a simple cycle if it has real central eigenvalues and:

1. \( p \) and \( q \) admit neighbourhoods \( U_p \) and \( U_q \) on which the expressions of \( f^{\pi(p)} \) and \( f^{\pi(q)} \) are linear and partially hyperbolic, with central dimension 1. We denote the coordinates of a point \((x^s, y^c, z^u)_p \) or \((x^s, y^c, z^u)_q \) according to whether it belongs to \( U_p \) or \( U_q \).
(2) There is a point \((0, y_0^+, 0)_p \in W^u(p) \cap W^s(q)\), with \(y_0^+ > 0\) such that \(f^r(0, y_0^+, 0)_p = (0, y_0^-, 0)_q\) with \(y_0^- < 0\) for some \(r > 0\), and a neighbourhood \(W \subset U_p\) of \((0, y_0^+, 0)_p\), such that \(f^r(W) \subset U_p\) and
\[
T_1 = f^r : W \to f^r(W)
\]
is an affine map preserving the partially hyperbolic splitting, and is contracting in the \(s\)-direction, expanding in the \(u\)-direction and an isometry in the central direction.

(3) There is a quasi-transverse heteroclinic point \((0, 0, z_0)_q \in W^s(p) \cap W^u(q)\) such that \(f^l(0, 0, z_0)_q = (x_0, 0, 0)_p\) for some \(l > 0\), and a neighbourhood \(V \subset U_q\) of \((0, 0, z_0)_q\) satisfying \(f^l(V) \subset U_p\) for which
\[
T_2 = f^l : V \to f^l(V)
\]
is an affine map preserving the partially hyperbolic splitting, which is contracting in the \(s\)-direction, expanding in the \(u\)-direction and an isometry in the central direction.

(4) There is a segment \(I = [y_0^-, \epsilon, y_0^+ + \epsilon]_p\) contained in \(W^u(p) \cap W^s(q)\), such that the form of \(f^l(I)\) in \(U_q\) is \(J = [y_0^-, \epsilon, y_0^+ + \epsilon]_q\).

We call the affine maps \(T_1\) and \(T_2\) the transitions of the simple heterodimensional cycle.

3.2. Preliminary results

In this subsection we state the preliminary results that shall be used in this work. The following, theorem 1.3 of [4], allows us to approximate conservative diffeomorphisms by transitive diffeomorphisms preserving \(m\):

**Theorem 3.9 (Bonatti and Crovisier [4]).** There exists a residual set of the set of diffeomorphisms preserving \(m\) such that all diffeomorphisms in this set is transitive. Moreover, \(M\) is the unique homoclinic class.

We shall use this theorem in combination with the connecting lemma below:

**Theorem 3.10 (connecting lemma [2] and [4]).** Let \(p, q\) be hyperbolic periodic points of a \(C^r\) transitive diffeomorphism \(f\) preserving a smooth measure \(m\). Then, there exists a \(C^1\)-perturbation \(g \in C^r\) preserving \(m\) such that \(W^s(p) \cap W^u(q) \neq \emptyset\).

The recent remarkable result by Ávila allows us to approximate \(C^1\) conservative diffeomorphisms by \(C^\infty\) conservative diffeomorphisms.

**Theorem 3.11 (Ávila [3]).** \(C^\infty\) diffeomorphisms are dense in the set of \(C^1\) diffeomorphisms preserving \(m\).

This following conservative version of Franks’ lemma is proposition 7.4 of [7]:

**Proposition 3.12 (Conservative version of Franks’ lemma [7]).** Let \(f\) be a \(C^r\) diffeomorphism preserving a smooth measure \(m\), \(S\) be a finite set. Assume that \(B\) is a conservative \(\epsilon\)-perturbation of \(Df\) along \(S\). Then for every neighbourhood \(V\) of \(S\) there is a \(C^1\)-perturbation \(h \in C^r\) preserving \(m\), coinciding with \(f\) on \(S\) and out of \(V\), such that \(Dh\) is equal to \(B\) on \(S\).

The fundamental tools in order to adapt the construction of Bonatti and Díaz [6] to the conservative case are the pasting lemmas of Arbieto and Matheus [1]. We shall need two such lemmas, one for vector fields and the other for diffeomorphisms. The following is theorem 3.1 of [1], and states that we can ‘paste’ two sufficiently \(C^1\)-close \(C^r\) vector fields, so that one gets the value of the first one on one set and the value of the second one on a disjoint set:
Theorem 3.13 (The \( C^{1+\alpha} \)-pasting lemma for vector fields). Given \( r > 1 \) and \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that if \( X, Y \in \mathcal{X}^r_u(M) \) are two \( C^r \) vector fields preserving a smooth measure \( m \) that are \( \delta \) \( C^1 \)-close on a neighbourhood \( U \) of a compact set \( K \), then there exist an \( m \)-preserving vector field \( Z \in \mathcal{X}^r_u(M) \) \( \varepsilon \)-\( C^1 \)-close to \( X \) and two neighbourhoods \( V \) and \( W \) of \( K \) such that \( K \subset V \subset U \subset W \) satisfying \( Z|_{M|W} = X \) and \( X|_V = Y \).

We shall also need the pasting lemma for diffeomorphisms, which states that we can produce a \( C^r \) diffeomorphism by ‘pasting’ a conservative diffeomorphism \( f \) with its derivative on a neighbourhood of a point.

Theorem 3.14 (The pasting lemma for diffeomorphisms). If \( f \) is a \( C^r \) diffeomorphism preserving a smooth measure \( m \) and \( x \) is a point in \( M \), then for any \( \varepsilon > 0 \), there exists a \( C^r \) diffeomorphism \( g \) preserving \( m \), \( \varepsilon \)-\( C^1 \)-close to \( f \) and two neighbourhoods \( V \) and \( U \) of \( x \) such that \( x \in V \subset U \) and \( g|_M|U = f \) and \( g|_V = Df(x) \) (in local charts).

4. Proof of theorem 2.2

Let \( f \) be a \( C^r \) diffeomorphism preserving a smooth measure \( m \), with two hyperbolic periodic points \( p \) and \( q \) of index \((u+1)\) and \((u)\) of index \( u \). Our first step is to show that \( f \) can be \( C^1 \)-approximated by a \( C^r \) diffeomorphism preserving \( m \) such that the analytic continuations of \( p \) and \( q \) form a co-index one heterodimensional cycle. Namely:

4.1. Proof of proposition 2.1

Proposition 2.1 follows in fact from the more general lemma:

Lemma 4.1. Let \( f \) be a \( C^r \) diffeomorphism preserving a smooth measure \( m \) such that \( f \) has two hyperbolic periodic points \( p \) and \( q \), then \( f \) is \( C^1 \)-approximated by \( C^r \) diffeomorphisms preserving \( m \) such that the continuations of \( p \) and \( q \) either form a heterodimensional cycle in case they have different indices or else they are homoclinically related.

Let us consider the case where \( p \) has unstable index \( u \) and \( q \) has unstable \( u' < u \). The case \( u = u' \) is simpler, and follows analogously. We shall apply the connecting lemma (Theorem 3.10) to produce the heterodimensional cycle. However, this lemma has transitivity as a hypothesis. So, let us consider a conservative diffeomorphism \( C \) is transitive. This \( f \), exists due to Theorem 3.9 by Bonatti and Crovisier. Note that \( f \) is a priori only \( C^1 \) and has two hyperbolic periodic points \( p \) and \( q \) which are the analytic continuations of \( p \) and \( q \). Now, due to its transitivity, the connecting lemma applies, and we can find a \( C^1 \)-close conservative diffeomorphism \( f_2 \) that \( W^u(p_2) \) intersects \( W^s(q_2) \), where \( p_2 \) and \( q_2 \) are the analytic continuations of \( p \) and \( q \). We can even ask that this intersection be transverse (it will be \( u - u' \)-dimensional). Note that since it is transverse, this intersection persists under \( C^r \)-perturbations. We will also ask, by using Theorem 3.9 again, that \( f_2 \) is transitive. Then, we apply the connecting lemma again, and obtain a new \( C^1 \) conservative diffeomorphism \( f_3 \) \( C^1 \)-close to \( f_2 \) so that \( W^u(p_3) \cap W^s(q_3) \neq \emptyset \) and \( y \in W^u(p_3) \cap W^s(q_3) \neq \emptyset \); we can even ask that this last intersection be quasi-transverse, i.e. \( T_y W^u(p_3) \cap T_y W^s(q_3) \) does not contain a non-trivial vector. But \( f_3 \) could be not \( C^1 \) a priori. Theorem 3.11 of Ávila yields a \( C^\infty \) conservative diffeomorphism \( f_4 \) \( C^1 \)-close to \( f_3 \). Since the stable and unstable manifolds of \( p_3 \) and \( q_3 \) vary continuously, we obtain that \( W^u(p_4) \cap W^s(q_4) \neq \emptyset \), and \( W^u(p_4) \) is close to \( W^u(q_4) \) near the point \( y \). There is a \( C^\infty \) conservative diffeomorphism \( f_5 \), \( C^1 \)-close to \( f_4 \), so that \( W^u(p_5) \) intersects \( W^s(p_5) \). This last perturbation can be made in fact \( C^\infty \). This gives the desired heterodimensional cycle. \(\square\)
4.2. Proof of theorem 2.2

Theorem 2.2 follows from lemmas 4.2 and 4.1. The idea of lemma 4.2 is as in lemma 4.2 of [11]. See also its generalization to dimension $n$ in lemmas 1.9 and 4.16 of [7]. The only difference is that we shall apply the pasting lemmas and the conservative Franks’ lemma instead of the corresponding results.

**Lemma 4.2.** Let $f$ be a conservative $C^r$ diffeomorphism with a hyperbolic periodic point $p$. Then $f$ is $C^1$-approximated by a $C^r$ conservative diffeomorphism with a hyperbolic periodic point $p'$ having the same index as $p$ such that the inequalities in equation (3.1) are strict.

In particular, the eigenvalues of $Df^\pi(p')$ are all real and of multiplicity one.

Let us assume $p$ is a hyperbolic fixed point for $f$ and let us denote the eigenvalues of $Df(p)$ as in equation (3.1). We may assume, by using the conservative Franks’ lemma (proposition 3.12), that the multiplicity of all the eigenvalues, complex or real, is one; and that any pair of complex eigenvalues with the same modulus are conjugated, and have rational argument. We shall also assume that $|\lambda^u_c(p)| < |\lambda_c^s(p)| = |\lambda^c_s(p)|$, and that $\lambda_c^s(p)$ and $\lambda^c_s(p)$ are complex conjugated eigenvalues. We shall prove that there is $p'$ such that $|\lambda^s_c(p')| < 1 < |\lambda^c_s(p')| < |\lambda^s_u(p')|$, whence $p'$ will have index $(u + 1)$, just like $p$. In fact, this is all we need, since the same argument applies to show there is $q'$ of index $u$ with real central (contracting) eigenvalue of multiplicity one. Lemma 4.2 follows from an inductive argument, since the fact that the eigenvalue is the central one is not used in the argument.

Using the connecting lemma (theorem 3.10) and genericity arguments we obtain a transverse homoclinic intersection $x \in W^s(p) \cap W^u(p) \setminus \{p\}$. Using the pasting lemma for diffeomorphisms (theorem 3.14) we can linearize $f$ in a small neighbourhood $V$ of $p$, so that $f$ remains the same outside a neighbourhood $U \supset V$. By considering sufficiently large iterates, we may assume that $x(x) \in W^u_{\text{loc}}(p) \cap V$ are such that the tangent spaces to $W^s(p)$ at $y$ and to $W^u(p)$ at $x$ are close enough to $E^u_p$ and $E^u_p$. The tangent space to $W^s(p)$ at $x$ and to $W^u(p)$ at $y$ are $E^c_p$ and $E^c_p$ due to the linearization.

Birkhoff–Smale provides a periodic point $p' \approx x$ with period $\pi(p') = n' + r$ where $n'$ is arbitrarily large, such that

1. $q' = f^n(p') \approx y$,
2. $f^i(p') \in V$ for all $i = 0, \ldots, n'$,
3. $p'$ is homoclinically related to $p$.

Let $E_{p'}^s = E^s_p + p'$ and $E_{q'}^s = E^s_p + q'$. Applying the conservative Franks’ lemma we obtain a perturbation such that

$$Df^s(q')E_{q'}^s = E_{p'}^s \quad \text{and} \quad Df^s(q')E_{q'}^u = E_{p'}^u.$$

A new perturbation allows us to ‘fix’ the eigenspace associated with $\lambda^c_s(p)$ and $\lambda^u_c(p)$, and obtain normal bases on which the derivative $Df^s(q') : T_qM \to T_{p'}M$ has the form

$$A = \begin{pmatrix} A_c & 0 & 0 \\ 0 & A_c & 0 \\ 0 & 0 & A_u \end{pmatrix},$$

where $A_c$ is a $2 \times 2$ matrix acting on a subspace $F_{q'}^c = F_p^c + q'$, where $F_p^c \subset E^u_p$ is the two-dimensional eigenspace associated with the eigenvalues $\lambda^c_s(p)$ and $\lambda^u_c(p)$.

Applying the conservative Franks’ lemma again we obtain that

$$Df^\pi(q')(q') = \begin{pmatrix} A_c^s(q') & 0 & 0 \\ 0 & A_c^s(q') & 0 \\ 0 & 0 & A_u^s(q') \end{pmatrix}, \quad A_c^\pi(q') = \begin{pmatrix} |\lambda^c_s(p)|^{\pi(q')} & 0 \\ 0 & |\lambda^u_c(p)|^{\pi(q')} \end{pmatrix}.$$
Creation of blenders in the conservative setting

Figure 2. Creating a simple cycle.

It is easy to produce now a perturbation so that the eigenvalues of $F_q^c$ are real and different. □

5. Creation of simple cycles

We may assume now that $f$ is a $C^r$ conservative diffeomorphism with a co-index one cycle having real central eigenvalues. Our main result will be established if we prove theorems 2.3 and 2.4. To do this, we shall perturb that in order to obtain a simplified model of the cycle, that is, a simple cycle. The creation of simple cycles follows the same arguments as in [6, proposition 3.5] and [8, lemma 3.2]. The only difference is that we shall use the pasting lemmas to linearize in the conservative setting. The goal of this section is to produce a simple cycle (figure 2).

Let us suppose that $p$ and $q$ are hyperbolic fixed points of indices $(u+1)$ and $u$, respectively. We may also assume that $W^s_q$ and $W^u(p)$ have a non-trivial transverse intersection, and $W^s(p)$ and $W^u_q$ have a point of quasi-transverse intersection. On $\{p, q\}$ we have a partially hyperbolic splitting $TM = E^s \oplus E^c \oplus E^u$, where $\dim E^u = u$, $\dim E^c = 1$ and $\dim E^s = s + u + 1 = n$. Using the pasting lemma for diffeomorphisms, we obtain two neighbourhoods $U_p$ and $U_q$ on which we can linearize $f$. We call this new $C^r$ conservative diffeomorphism $g$. $g$ equals $Df(p)$ on $U_p$ and $Df(q)$ on $U_q$; the strong stable and unstable manifolds are, respectively, the $s$- and $u$-planes parallel to $E^s_p$ and $E^u_p$ or $E^s_q$ and $E^u_q$. The centre lines parallel to $E^c_p$ and $E^c_q$ are also invariant under $g$.

We can choose $g$ so that there is a point of transverse intersection $X$ of $W^u(p)$ and $W^s(q)$, and a point of quasi-transverse intersection $Y$ of $W^s(p)$ and $W^u(q)$. There is a sufficiently large iterate $m > 0$ so that $g^{-m}(Y) = (0, 0, z_0)_q \in W^u_{loc}(q)$ and $g^m(Y) = (x_0, 0, 0)_p \in W^s_{loc}(p)$. Take $l = 2m$.

Now, generically $W^u(p) \pitchfork W^s(q)$ is transverse to the strong unstable in $U_p$ and to the strong stable foliation in $U_q$. So, take a curve $\alpha \subset W^u(p) \pitchfork W^s(q)$ and iterates $m > 0$ so large that $g^{-m}(\alpha)$ is the graphic of a map $\gamma_p : I \to E^{su}$, and $f^m(\alpha)$ is the graphic of a map $\gamma_q : J \to E^{su}$. $I$ and $J$ are small segments contained, respectively, in $W^c_{loc}(p)$ and $W^c_{loc}(q)$. Note that $g^{-m}(\alpha)$ approaches $W^c_{loc}(p)$ exponentially faster than it approaches $p$; analogously $g^m(\alpha)$ approaches $W^c_{loc}(q)$ exponentially faster than it approaches $q$. Hence we can choose $m > 0$ so large that $\gamma_p$ and $\gamma_q$ are $C^1$-close to zero.

Let us define $C^r$ vector fields $X_p$ and $X_q$ in suitable neighbourhoods of $I \cup \text{Graph}(\gamma_p)$ and $J \cup \text{Graph}(\gamma_q)$. We define $X_p$ as a vector field that is constant along the hyperplanes parallel to $E^{ss} \oplus E^{uu}$, such that $X_p(x, y, z)_p = \gamma_p(0, y, 0)_p$. That is, $X_p$ assigns to each point its centre coordinate. Since $X_p$ is constant along the hyperplanes parallel to $E^{ss} \oplus E^{uu}$ it is divergence
free and is very close to the null vector field. Then we can apply the pasting lemma for flows (theorem 3.13) and paste $S$ with the null vector field obtaining a $C^r$-vector field $\bar{X}$ that is $C^1$-close to the null vector field. By composing our diffeomorphism with the time-one map of $\bar{X}$ we have a perturbation of $g$ (which we continue to call $g$) such that $g^{-2m}(\text{Graph}(\gamma_0))$ is contained in $W^{loc}_{loc}(p)$. Analogously, we obtain a $C^1$-perturbation, so that $g^{2m}(I) \subset W^{loc}_{loc}(q)$. In this way, we have obtained so far the points $(0, 0, z_0)_q$, $(x_0, 0, 0)_p$, $(0, y^*_0, 0)_p$ and $(0, y_0, 0)_q$.

Let us apply the pasting lemma for diffeomorphisms again, so that we obtain a new perturbation for which the transitions $T_1 = g^1|_V$ and $T_2 = g^1|_W$ are affine maps, where $V$ and $W$ are small neighbourhoods of $(0, 0, z_0)_q$ and $(0, y^*_0, 0)_p$, respectively. We lose no generality in assuming that the images of the hyperplanes $E^{ss}, E^{uu}, E^c, E^{ss} \oplus E^c$ and $E^{uu} \oplus E^c$ are in general position. By taking $l > 0$ sufficiently large, one obtains that the image of the centre-unstable foliation becomes very close to the $E^{uu} \oplus E^c$ in $U_p$. A small perturbation using the pasting lemma for vector fields as in the previous paragraph gives us an invariant centre-unstable foliation. Indeed, there exists a matrix $A$ with $\det(A) = 1$, close to the identity, taking the image of the centre-unstable foliation in $W \subset U_p$ into the centre-unstable foliation of $g^l(W) \subset U_q$. But now, there exists a vector field log $A$ such that the time-one map of log $A$ is $A$. We use the pasting lemma for vector fields to paste log $A$ in a neighbourhood of $(0, y^*_0, 0)_p$ in $g^l(W)$ with the identity outside of $g^l(W)$. Composing $g$ with the time-one map of this vector field, we get $C^r$ diffeomorphisms $C^1$-close to $g$ such that $g^{l+1}$ leaves the centre-unstable foliation invariant. We replace $g^l(W)$ by $g^{l+1}(W)$, and $T_2$ by this new affine transition.

Let us continue to call $g$ this new $C^r$ conservative diffeomorphism, and $T_2$ the new transition. In order to get the invariance of the strong stable foliation, note that by the previous construction, the centre-unstable foliation is preserved by backward iterations. The backward iterations of the strong stable foliation approach the strong stable foliation in $U_p$. If necessary, we may replace $(0, y^*_0, 0)_p$ by a large backward iterate, and $W$ by a corresponding iterate in $U_p$. There is a matrix $B$ with $\det(B) = 1$ close to the identity, that preserves the centre-unstable foliation and is such that $B \circ g^l|_W$ preserves the strong stable and centre-stable foliations. Proceeding as in the previous paragraph, we obtain a $C^1$-close diffeomorphism preserving these foliations. We can now repeat the same argument inside the centre-unstable foliation in order to get the invariance of the strong unstable and the centre foliations. In this way we obtain an affine partially hyperbolic transition $T_2$ preserving $E^{ss}, E^{uu}$ and $E^c$. Analogously we obtain $T_1$.

We only need to show that we can perturb in order to obtain that the transitions $T_1$ and $T_2$ are isometries on the centre foliations. Now we can replace $T_1$ by $T_1(m_1, m_2) = Dg^{-m_2}(p) \circ T_1 \circ Dg^{m_1}(q)$ with large $m_1, m_2 > 0$ on a suitable small neighbourhood of $g^{-m_1}(0, 0, z_0)_q$. There are infinitely many $m_1, m_2 > 0$ such that the centre eigenvalues of $T_1(m_1, m_2)$ are in a bounded away from zero finite interval. Considering $m_1$ and $m_2$ sufficiently large, and changing $(0, 0, z_0)_q$ by a point $X$ with coordinates of the same form, we obtain a $C^1$-perturbation in a small neighbourhood of the segment of orbit $X, g(X), \ldots, g^r(X) \in U_q$, where $r = m_1 + l + m_2$, such that the action of $T_1(m_1, m_2)$ in the central direction is an isometry. The perturbation is produced using the pasting lemma for vector fields as in the previous paragraphs. In an analogous way we obtain a transition $T_2$ acting as an isometry in the central direction.

We have proved the following proposition.

**Proposition 5.1.** Let $f$ be a $C^r$ conservative diffeomorphism having a co-index one cycle with real central eigenvalues associated with the points $p$ and $q$. Then $f$ can be $C^1$-approximated by $C^r$ conservative diffeomorphisms having simple cycles associated with $p$ and $q$. 
6. Proof of theorem 2.3

For simplicity we shall assume that \( p \) and \( q \) are fixed points, and that the co-index cycle is a simple cycle. We shall call \( \kappa_c(p) = \mu \) and \( \kappa_c(q) = \lambda \). We shall assume that \( \mu > 1 \) and \( \lambda \in (0, 1) \), since no greater complication appears in the cases \( \mu < -1 \) and \( \lambda \in (-1, 0) \).

Since the cycle is simple, there are coordinates \((x, y, z)_p\) and \((x, y, z)_q\) in suitable neighbourhoods of \( p = (0, 0, 0)_p \) and \( q = (0, 0, 0)_q \) on which the expression of \( f \) is

\[
A(x, y, z)_p = (A_s x, \mu y, A_u z)_p \quad \text{and} \quad B(x, y, z)_q = (B_s x, \lambda y, B_u z)_q,
\]

(6.1)

where \( A_s, B_s \) are contractions, and \( A_u, B_u \) are expansions. We recall that there are points \((0, 0, z_0)_q\) in the quasi-transverse intersection of \( W^s(p) \cap W^u(q) \), and \((0, y^+, 0)_p\) in the transverse intersection of \( W^u(p) \cap W^s(q) \) such that on suitable neighbourhoods \( V \subset U_q \) and \( W \subset U_p \) the transitions \( T_1 = f_1 \mid_V \) and \( T_2 = f_2 \mid_W \) have the form

\[
T_1(x, y, z)_p = (T_s^1 x + y - y^+, T_u^1 z)_q
\]

(6.2)

and

\[
T_2(x, y, z)_q = (T_s^2 x + x_0, y, T_u^2 (z - z_0))_p,
\]

(6.3)

where \( T_s^1, T_s^2 \) are contractions and \( T_u^1, T_u^2 \) are expansions.

We shall produce a continuous family of perturbations \( \{f_t\}_{t \geq 0} \) of \( f \) shifting the unstable manifold of \( q \) in \( U_p \) so that it does not intersect \( W^{uu}(p) \), see figure 3. These perturbations preserve the bundles \( E^{ss}, E^c \) and \( E^{uu} \). In this form, they induce maps of the interval on \( E^c \). By eventually changing the original \( \lambda \in (0, 1) \) and \( \mu > 1 \) (so that \( f_t \) continues to be conservative), and carefully choosing a small parameter \( t > 0 \), we may obtain that the \( E^{uu} \oplus E^{uu} \) plane containing the point \((0, y^+, 0)_p\) is periodic by two different (large) itineraries. Now, the dynamics \( f_t \) on this periodic plane is hyperbolic, then using a Markovian property, we get two periodic points that are homoclinically related within this plane. The \( \lambda \)-lemma now gives a periodic point with a strong homoclinic intersection.

Proceeding as in section 5 we take a divergence-free vector field \( X \) supported in a small neighbourhood of \( f^{-1} \mid_V \), so that the composition \( f_t \) of \( f \) with the time- \( t \) map of \( X \) forms a \( C^1 \)-family of \( C^r \) conservative diffeomorphisms admitting transitions \( T_1 \) of the form (6.3) and \( T_2, t \) of the form

\[
T_2, t(x, y, z)_q = T_2(x, y, z)_q + (0, t, 0)_p,
\]

(6.4)

where \( T_2 \) is as in formula (6.3). Since \( Df_t(p) = Df(p) \) and \( Df_t(q) = Df(q) \), formulae (6.1) hold for all small \( t > 0 \).
Note that if the composition $f^n \circ f^t \circ f^m \circ f_1$ makes sense for some point and takes a small neighbourhood of $(0, y^*, 0)_p$ into $U_p$ then, due to the above formulae, its centre coordinate takes the form

$$\psi^{m,n}_t(y) = \mu^n [\lambda^m(y + \Delta y) + t]$$

where $\Delta y = y^* - y^*$. \hfill (6.5)

Conversely, we have the following lemma.

**Lemma 6.1.** If $m, n, t > 0$ are such that $\psi^{m,n}_t(y^*) = y^*$ with sufficiently large $m, n$, then there is a point

$$p_{m,n} = (\lambda^{m,n}, y^*, z_{m,n})_p$$

in the $E^s \oplus E^{uu}$ plane through $(0, y^*, 0)_p$ that is $f^t$-periodic, with period $\pi(p_{m,n}) = n + l + m + r$.

Its centre eigenvalue is $\lambda^c(p_{m,n}) = \mu^n \lambda^m$.

If there is $(m', n') \neq (m, n)$ for which $\psi^{m',n'}_{t'}(y^*) = y^*$, then there is a point $q_{m,n}$, such that

$$q_{m,n} \subseteq W^{uu}(p_{m,n}) \cap W^{ss}(p_{m,n}).$$

That is, $p_{m,n}$ has a strong homoclinic intersection that is quasi-transverse.

**Proof.** Let $t > 0$ be a small parameter, and let $m, n > 0$ be sufficiently large. Suppose that $\psi^{m,n}_t(y^*) = (y^*)$. Then it is easy to see that the $f^{m+n+t}$ image of the $su$-disc $[-1, 1]^t \times \{y^*\} \times [-1, 1]^n$ contains a cylinder of the form

$$C^u = B^u_{\delta}(A^y x_0) \times \{y^*\} \times [-1, 1]^n,$$

for some sufficiently small $\delta > 0$, where $B^u_{\delta}(x)$ denotes the $s$-disc of radius $\delta$ centred at $x$.

Analogously, we obtain that the $f^{m+n+t}$ pre-image of the $su$-disc $[-1, 1]^t \times \{y^*\} \times [-1, 1]^n$ contains a cylinder of the form

$$C^s = [-1, 1]^t \times \{y^*\} \times B^s_{\delta}(z),$$

for some $z \in (-1, 1)^n$ and some suitable small $\delta$, which can be taken equal to the previous one. $B^u_{\delta}(z)$ denotes the $u$-disc of radius $\delta$ centred at $z$. This implies the existence of a periodic point $p_{m,n}$ of period $\pi(p_{m,n}) = n + l + m + r$. The fact that the transitions are isometries on the central direction implies that $\lambda^c(p_{m,n}) = \mu^n \lambda^m$.

If $(m', n') \neq (m, n)$ are such that $\psi^{m',n'}_{t'}(y^*) = y^*$, then the previous argument gives us a periodic point $p_{m',n'}$ which, by construction, is different from $p_{m,n}$. Due to linearity, the unstable manifolds of $p_{m,n}$, $p_{m',n'}$ are, respectively, the $u$-discs $W^{uu}(p_{m,n}) = (\lambda^{m,n}, y^*) \times [-1, 1]^n$ and $W^{uu}(p_{m',n'}) = (\lambda^{m',n'}, y^*) \times [-1, 1]^n$. Also, $W^{ss}(p_{m,n}) = [-1, 1]^t \times (y^*, z_{m,n})$ and $W^{ss}(p_{m',n'}) = [-1, 1]^t \times (y^*, z_{m',n'})$. The $u$-discs transversely intersect the $u$-discs in the $su$-plane. Therefore, $p_{m,n}$ and $p_{m',n'}$ are homoclinically related in the $su$-plane, that is

$$W^{uu}(p_{m,n}) \cap W^{ss}(p_{m,n}) \neq \emptyset$$

and

$$W^{uu}(p_{m,n}) \cap W^{ss}(p_{m',n'}) \neq \emptyset.$$

The $\lambda$-lemma implies the existence of a point $q \neq p_{m,n}$ in the intersection of the strong stable and strong unstable manifolds of $p_{m,n}$. The expression of $f_t$ in $U_p$ implies that this intersection is quasi-transverse. \hfill \Box

The proof of theorem 2.3 will be completed after the following lemma.

**Lemma 6.2 (Bonatti et al [9]).** For any $\varepsilon > 0$ there are $\mu_0$, $\lambda_0$, $t$, $m$, $n$, $n'$ such that $|\lambda_0 - \lambda| < \varepsilon$, $|\mu_0 - \mu| < \varepsilon$, $|t| < \varepsilon$ and $m, n$ arbitrarily large with $n < n'$ and

1. $\psi^{m+n}_t(y^*) = y^*$,

2. $\psi^{m+n}_t(y^*) = y^*$. 

This is proved in lemma 3.11 of [6]. The proof of theorem 2.3 now ends by taking $n, m$ so that $\mu_0^n>1$. With the techniques used in section 5 we can produce a $C^1$ perturbation so as to obtain a $C^r$ conservative diffeomorphism where the linear expressions (6.1) are such that the centre coordinate expansions are, respectively, $\lambda_0$ and $\mu_0$.

Theorem 2.4 has been proved in [9] and in theorem 2.1 of [5], see also section 4.1 of [6]. Note that the perturbations can be trivially made so that the resulting diffeomorphism be $C^r$ and conservative.

Acknowledgments

The authors are grateful to Bonatti and Díaz for providing us with a preliminary version of [6]. Tahzibi was enjoying a post-doctoral period at IMERL, supported by CNPq, Brazil.
