ABSTRACT

We identify the operators in $\mathcal{N} = 4$ super Yang-Mills theory that correspond to $\frac{1}{8}$-BPS giant gravitons in $\text{AdS}_5 \times S^5$. Our evidence for the identification comes from (1) counting these operators and showing agreement with independent counts of the number of giant graviton states, and (2) by demonstrating a correspondence between correlation functions of the super Yang-Mills operators and overlaps of the giant graviton wave functions.

1 Introduction

The AdS/CFT correspondence[1] provides a beautiful realization of 't Hooft’s proposal that the large N limit of Yang-Mills theories are equivalent to string theory[2]. Most studies of the correspondence have focused on the planar limit, which holds classical operator dimensions fixed as we take \( N \rightarrow \infty \). There are non-planar large \( N \) limits of the theory [3], which are defined by considering operators with a bare dimension that is allowed to scale with \( N \) as we take \( N \rightarrow \infty \). These limits are relevant for the AdS/CFT correspondence. The limit on which we will focus in this study considers operators with a dimension that scales as \( N \). Our focus is on operators relevant for the description of giant graviton branes[4, 5, 6].

The worldvolume of the most general \( \frac{1}{8} \)-BPS giant graviton can be described as the intersection of a holomorphic complex surface in \( \mathbb{C}^3 \) with the five sphere \( S^5 \) of the AdS_5 \times S^5 spacetime[7]. It is possible to quantize these giant graviton configurations and then to count them[8]. Remarkably, this quantization leads to the Hilbert Space of \( N \) noninteracting Bose particles in a 3d harmonic oscillator potential, a result conjectured in [9]. In [10] \( \frac{1}{8} \)-BPS states which carry three independent angular momenta on \( S^5 \) were counted. This counting problem can again be mapped to counting energy eigenstates of a system of \( N \) bosons in a 3-dimensional harmonic oscillator. Both of these analysis [8, 10] make use of a world volume description of the branes. Finally, an index to count single trace BPS operators operators has been constructed [11, 12]. The index has been computed both at weak coupling (using the gauge theory) and at strong coupling (as a sum over the spectrum of free massless particles in AdS_5 \times S^5) and the results again agree with [8, 10].

Given the AdS/CFT correspondence, this counting should also arise in the dual \( \mathcal{N} = 4 \) super Yang-Mills theory, when the operators of a bare dimension of order \( N \) and vanishing anomalous dimension are considered. One of our goals in this study is to demonstrate this.

A crucial ingredient in the study of operators with a bare dimension of order \( N \), has been the construction of bases of operators developed in [13, 14, 15, 16, 17, 18, 19, 20]. These bases diagonalize the free field theory two point function to all order in \( 1/N \) and mix weakly when the Yang-Mills coupling is switched on. Using these bases as a starting point,
the spectrum of anomalous dimensions for a class operators of bare dimension of order \( N \) has been computed in \[21, 22, 23\]. The operators are constructed using the three complex adjoint scalars \( Z, Y \) and \( X \). We use \( n \) \( Z \)'s, \( m \) \( Y \)'s and \( p \) \( X \)'s, fixing \( n \approx N \) and \( m, p \ll n \). This implies that we are focusing on small deformations of \( \frac{1}{2} \)-BPS giant gravitons. The operators of a definite scaling dimension are labeled by a permutation \( \sigma \in S_m \times S_p \) and a triple of Young diagrams \( R \vdash n + m + p \) and \( r \vdash n \). The explicit form of these operators is

\[
O_{R,r}^{\bar{m}, \bar{p}}(\sigma) = \frac{|H_X \times H_Y|}{\sqrt{p!m!}} \sum_{j,k} \sum_{s,m} \sum_{t,p} \sum_{\bar{m}_1 \bar{m}_2} \sqrt{d_s d_t} \Gamma^{(s,t)}_{j,k}(\sigma) \times B^{(s,t) \rightarrow 1 H_X \times H_Y}_{j \bar{m}_1} B^{(s,t) \rightarrow 1 H_X \times H_Y}_{k \bar{m}_2} O_{R,(r,s,t)\bar{m}_1 \bar{m}_2} \quad (1.1)
\]

The Young diagrams \( R \) and \( r \) both have \( q \) rows for operators dual to a state of \( q \) giant gravitons. Each box in \( R \) is associated with one of the complex fields, so that we can talk of a box as being a \( Z \) box, a \( Y \) box or an \( X \) box. \( r \) collects all of the \( Z \) boxes. The difference in the row length of the \( q \)th row in \( R \) and \( q \)th row in \( r \) is equal to the number of \( X \)'s (= \( m_q \)) and \( Y \)'s (= \( m_q \)) in row \( q \), so that \( R_q - r_q = m_q + p_q \). The right most boxes are \( X \) boxes, the left most boxes \( Z \) boxes and the \( Y \) boxes are sandwiched in the middle. The \( q \) dimensional vector \( \bar{m} \) collects the \( m_i \), while \( \bar{p} \) collects the \( p_i \). The branching coefficients \( B^{(s,t) \rightarrow 1 H_X \times H_Y}_{j \bar{m}_1} \) resolve the operator that projects from \( (s,t) \), with \( s \vdash m \), \( t \vdash p \), an irreducible representation of \( S_m \times S_p \), to the trivial (identity) representation of the product group \( H_Y \times H_X \) with \( H_Y = S_{m_1} \times S_{m_2} \times \cdots S_{m_q} \) and \( H_X = S_{p_1} \times S_{p_2} \times \cdots S_{p_q} \), i.e.

\[
\frac{1}{|H_X \times H_Y|} \sum_{\gamma \in H_X \times H_Y} \Gamma^{(s,t)}_{j,k}(\gamma) = \sum_{\bar{m}} B^{(s,t) \rightarrow 1 H_X \times H_Y}_{j \bar{m}_1} B^{(s,t) \rightarrow 1 H_X \times H_Y}_{k \bar{m}_2} \quad (1.2)
\]

The operators \( O_{R,(r,s,t)\bar{m}_1 \bar{m}_2} \) are normalized versions of the restricted Schur polynomials \[18\]

\[
\chi_{R,(r,s,t)\bar{m}_1 \bar{m}_2}(Z, X, Y) = \frac{1}{n!m!p!} \sum_{\sigma \in S_{n+m+p}} \chi_{R,(r,s,t)\bar{m}_1 \bar{m}_2}(\sigma) \text{Tr}(\sigma Z^{\otimes n} Y^{\otimes m} X^{\otimes p}), \quad (1.3)
\]

which themselves provide a basis for the gauge invariant operators of the theory. The restricted characters \( \chi_{R,(r,s,t)\bar{m}_1 \bar{m}_2}(\sigma) \) are defined by tracing the matrix representing group element \( \sigma \) in representation \( R \) over the subspace giving an irreducible representation \( (r, s, t) \) of the subgroup \( S_n \times S_m \times S_p \). There is more than one choice for this subspace and the multiplicity labels \( \bar{m}_1 \bar{m}_2 \) resolve this ambiguity. The operators \( O_{R,(r,s,t)\bar{m}_1 \bar{m}_2} \) given by

\[
O_{R,(r,s,t)\bar{m}_1 \bar{m}_2} = \sqrt{\text{hooks} \times \text{hooks} \times \text{hooks} \times \text{hooks} \times \text{hooks}} \chi_{R,(r,s,t)\bar{m}_1 \bar{m}_2} \quad (1.4)
\]

have unit two point function. Although the definition of the Gauss graph operators \( O_{R,r}(\sigma) \) is technically rather involved, they have a very natural and simple interpretation in terms of the dual giant graviton branes plus open string excitations. A Gauss graph operator that is labeled by a Young diagram \( R \) that has \( q \) rows corresponds to a system of \( q \) giant
gravitons. The $Y$ and $X$ fields describe the open string excitations of the giants. Each such field corresponds to a directed edge, an open string, which can end on any two (not necessarily distinct) of the $q$ branes. The permutation $\sigma \in S_m \times S_p$ is a label which tells us precisely how the $m$ $Y$’s and the $p$ $X$’s are draped between the $q$ giant gravitons. The picture of directed edges stretched between $q$ dots is highly suggestive of a brane plus open string system, as reflected in our language. This interpretation is further supported by that fact that the only configurations that appear have the same number of strings starting or terminating on any given giant. This nicely implements the Gauss Law of the brane world volume theory implied by the fact that the giant graviton has a compact world volume. The Gauss graph operators which correspond to BPS states have all open strings described by loops that start at a given giant and loop back to the same giant, i.e. no open strings stretch between giants. In this case, we simply need to specify which brane the open string belongs to and this is most conveniently done by partially labeling Young diagram $R$: in each box we place a $z$, an $x$ or a $y$. Each row in the operator consists mainly of $Z$ fields, corresponding to the fact that the unexcited giant graviton is dual to a half-BPS operator built only from $Z$s. The number of $x$ and $y$ boxes in a given row tell us how many $X$ and $Y$ strings attach to the corresponding giant.

In the next section we will show the counting of these BPS states agrees with the counting of \cite{8,10}. Motivated by this observation, we explore the link between the $N$ particle description employing the 3d harmonic oscillator and the super Yang-Mills operators in section \ref{sec:3}. Our results shed light on the attractive possibility of an $N$ particle description of multi matrix models, suggesting that there maybe an extension of the famous free fermion/eigenvalue description of single matrix models \cite{24}. Finally, we refer the reader to \cite{25} and \cite{26} for further related background.

\section{Counting}

As discussed in the introduction, our description of $\frac{1}{8}$-BPS operators is in terms of a Young diagram $R$ with partially labeled boxes. When the boxes corresponding to $Y$ and $X$ fields are removed from the rows of $R$, we are left with the valid Young diagram $r$. An example of a valid $\frac{1}{8}$-BPS operator is

$$\begin{array}{cccccccc}
  z & z & z & z & z & y & y & x \\
  z & z & z & z & z & y & x \\
  z & z & z & z & y & y 
\end{array}$$

(2.1)

The boxes with label $z$ belong to the Young diagram $r$ and the boxes with label $y$ or $x$ are the ones that are removed from the Young diagram $R$ to obtain $r$. The operator labeled by the Young diagram shown in (2.1) corresponds to a system of 3 giant gravitons, with 2 $Y$ strings and an $X$ string attached to the first giant, a $Y$ and an $X$ string attached to the second giant and 2 $Y$ strings attached to the third giant. This description in terms of Gauss
graph operators is valid in the case where \( n \) the total number of boxes of the Young diagram \( r \) and \( m + p \) the total number of the boxes that are added to the Young diagram \( r \) to form \( R \), are both large and of order \( N \gg 1 \). In addition, \( m + p \ll n \) and the number of rows of the Young diagram \( R \) is of order \( 1 = N^0 \). Finally, the length of any row of \( R \) is of order \( N \), as is the difference between the length of any two consecutive rows.

Let us first start by fixing our notation. We will denote by \( R_i \) the number of boxes in the \( i \)th row of \( R \), and we will denote by \( m_i \) and \( p_i \) the number of \( Y \) and \( X \) boxes to be removed from the \( i \)th row of \( R \) to obtain \( r \). Furthermore, \( q \) will stand for the number of rows of \( R \), \( n \) will stand for the total number of boxes of \( r \), \( m = \sum_{i=1}^{q} m_i \) and \( p = \sum_{i=1}^{q} p_i \). Hence, the total number of boxes of \( R \) is then \( n + m + p \). If we denote by \( r_i \) the number of boxes in the \( i \)th row of \( r \), then we have

\[
 r_i = R_i - m_i - p_i
\]

In our conventions, we start the numbering of rows from top to bottom. As already mentioned above, this description of \( \frac{1}{8} \)-BPS states is proved to work\textsuperscript{22} in the cases that

\[
 R_i \sim N \quad R_{i+1} - R_i \gg m + p \sim N \quad q \sim N^0
\]

(2.2)

We call this the displaced corners approximation because the neighboring corners of \( R \) are separated by a huge number of columns. Outside this regime, things are more complicated and it is not even known if partially labeled Young diagrams can be used to describe these \( \frac{1}{8} \)-BPS states. The number of \( \frac{1}{8} \)-BPS operators is the same as the number of possible pairs \((R; r)\) counted with multiplicity equal to the number of ways of assigning a valid vector \( \vec{m} = (m_1, m_2, \ldots, m_q) \). Note that once the pair \((R; r)\) and the vector \( \vec{m} \) are given, the vector \( \vec{p} = (p_1, p_2, \ldots, p_q) \) is determined. The first step towards counting the number of Gauss graph operators entails writing a generating function for the number of pairs \((R; r)\). Our starting point is the observation that the Young diagrams are in one to one correspondence with partitions of integers. The generating function of the latter is given by

\[
 Z = \prod_{n=1}^{\infty} \frac{1}{1 - q^n} = \sum_{k=0}^{\infty} D_k q^k
\]

(2.3)

where \( D_k \) is the number of possible ways to partition an integer \( k \). This counting is too coarse for us to reach our goals: we need to track the number of parts in the partition which corresponds to the number of rows in the Young diagram. Indeed, we must encode the information about \( q \) the number of rows of \( R \), as well as the information about the different possible \( m_i \)'s and \( p_i \)'s in such a partition, to ensure that we are counting states in the regime in which the Gauss graph operators provide a trustworthy description. Both modifications are easy to take into account in our case of interest where \( m_i + p_i + r_i \ll m_{i+1} + p_{i+1} + r_{i+1} \) for all values of \( i = 1, 2, \ldots, q \). The number of ways to partition an integer \( k \) is given by the number of solutions to the equation

\[
 k = \sum_{i} \chi_i n_i \quad n_1 \geq n_2 \geq \cdots > 0 \quad \chi_i \geq 0
\]

(2.4)
Notice that the term \( \chi_i n_i \) in the above equation is associated to the term \((q^n_i)^{\chi_i}\) in the expansion of \( Z \). This term appears in the expansion for the term \((1 - q^n)^{-1}\). Clearly then, to keep track of contributions from different rows \( \chi_i \) we just need to multiply \( q^n \) by an extra parameter \( \chi \) and track the power of \( \chi \). So, we consider the following modification of the partition function \( Z \)

\[
Z = \prod_{i=1}^{\infty} \frac{1}{1 - \chi q^n} = \sum_{k,d=0}^{\infty} D_{k,d} \chi^d q^k
\]

where \( D_{k,d} \) counts the number of Young diagrams with \( k \) boxes and \( d \) rows. Next consider the information associated to the \( m_i \)’s and \( p_i \)’s. There is a potential complication because we want both \( R \) and \( r \) to be Young diagrams. However, in the displaced corners limit, we can ensure that this is not an issue. Indeed, by taking \( m_i, p_i \ll |r_{i+1} - r_i| \) for all \( i \), we ensure that we can never pile enough \( Y \) and \( X \) boxes onto a row to make it longer than the row above it. Thus, we may treat the \( m_i \)’s and \( p_i \)’s as independent, except for the requirement that \( \sum_{i=1}^{n} m_i = m \) and \( \sum_{i=1}^{d} p_i = p \). In terms of the partition function \( Z \), this is equivalent to associating to each term \( q^n \) in the product form of \( Z \) in equation (2.5). Thus, we finally obtain the generating function

\[
Z = \prod_{l=0}^{\infty} \prod_{m=0}^{\infty} \prod_{n=0}^{\infty} \frac{1}{1 - \chi p^l r^m q^n} = \sum_{d,m,p,n} D_{m,p,n;d} \chi^d p^l r^m q^n
\]

where \( D_{m,p,n;d} \) counts the number of diagrams \( R \) with \((n + m + p) \) boxes and \( d \) rows, that is the result of adding \( m + p \) boxes that are randomly distributed over the \( d \) rows of the Young diagram \( r \) with \( n \) boxes. Our construction of the Gauss graph operators only holds when the displaced corners approximation holds. Thus, we trust \( D_{m,p,n;d} \) to count the number of Gauss graph operators for a system of \( d \sim N^{0} \) giant gravitons when \( n, m, p \sim N \) and \( n \gg m + p \). This is the main result of this section.

We want to compare this to the counting of \( \frac{1}{8} \) BPS giant gravitons. As we discussed in the introduction, this counting problem can be mapped to counting energy eigenstates of a system of \( N \) bosons in a 3-dimensional harmonic oscillator. The grand canonical partition function for bosons in a 3-dimensional simple harmonic oscillator is given by

\[
Z(\zeta, q_1, q_2, q_3) = \prod_{n_1=0}^{\infty} \prod_{n_2=0}^{\infty} \prod_{n_3=0}^{\infty} \frac{1}{1 - \zeta q_1^{n_1} q_2^{n_2} q_3^{n_3}}
\]

with the fugacity \( \zeta \) being dual to particle number [10]. Notice that (2.6) exactly matches the grand canonical partition function (2.7) for bosons in a harmonic oscillator potential with \( \chi \) playing the role of the fugacity. This is in harmony with the fact that the number of rows matches the number of giant gravitons. In the 3-dimensional harmonic oscillator we have 3
types of excitations, counted by $q_1$, $q_2$ and $q_3$. These map into the three types of boxes ($X$, $Y$ or $Z$ boxes) appearing in $R$, counted by $p$, $q$ and $r$. Thus, long rows in $R$ map to highly excited particles. This proves our first claim: the counting of the Gauss graph operators matches the counting of $\frac{1}{8}$ BPS giant gravitons.

3 Matching States to Operators

The fact that the number of Gauss graph operators matches the number of energy eigenstates states of a system of bosons in a 3-dimensional harmonic oscillator potential, motivates us to look for a correspondence between the two. To start we will consider operators $O_{R,r}^{\tilde{m}, \tilde{r}}(\sigma)$ labeled by Young diagrams that have a single row. In this case we don’t need to encode a complicated shape for $R$, so we will simply list the number of $Z$s, $Y$s and $X$s in the operator as $O_{n,m,p}$. Since this row has $O(N)$ boxes, we have a system of $N$ bosons and one of them is highly excited. The idea is that since we have one highly excited particle, we can use a single particle description and overlaps of the single particle wave functions will match correlation functions of Gauss graph operators in the CFT. We focus on $R$’s with a single row because the computations are so simple to carry out in this case that we can compute many quantities exactly. There is a simple formula for the Gauss graph operators we consider, in terms of the Schur polynomials

$$O_{n,m,p}(Z, Y, X) = N \text{Tr} \left( Y \frac{d}{dZ} \right)^m \text{Tr} \left( X \frac{d}{dZ} \right)^p \chi_{(n+m+p)}(Z)$$

where

$$N = \sqrt{\frac{n!(N-1)!}{m!p!(n+m+p)!(N+n+m+p-1)!}}$$

We are using the notation $(k)$ to denote a Young diagram that has a single row of $k$ boxes. There are a number of natural operators that act on the Gauss graphs. For example, we have

$$\text{Tr}(Y \frac{d}{dZ})^{k_1} \text{Tr}(X \frac{d}{dZ})^{k_2} O_{n,m,p}(Z, Y, X) \propto O_{n-k_1-k_2,m+k_1,p+k_2}(Z, Y, X)$$

Thus, a natural correlator to consider is given by

$$\langle O_{n-k_1-k_2,m+k_1,p+k_2}^{\dagger} \left( Y \frac{d}{dZ} \right)^{k_1} \text{Tr} \left( X \frac{d}{dZ} \right)^{k_2} O_{n,m,p} \rangle = \sqrt{\frac{(m+k_1)!(p+k_2)!n!}{m!p!(n-k_1-k_2)!}}$$

To describe a single particle in a 3d harmonic oscillator, we need three sets of creation and annihilation operators

$$[a_z, a_z^\dagger] = [a_y, a_y^\dagger] = [a_x, a_x^\dagger] = 1$$
Using the above oscillators we can create a state with an arbitrary number of $z$ quanta, $y$ quanta or $x$ quanta. We suggest that the correspondence between Gauss graph operators and particle states is as follows

$$O_{n,m,p} \leftrightarrow |O_{n,m,p}\rangle = \frac{1}{\sqrt{n!m!p!}} (a_x^\dagger)^m (a_y^\dagger)^n (a_z^\dagger)^p |0\rangle \quad (3.6)$$

The correspondence identifies the number of $z$, $y$ or $x$ quanta in the particle state with the number of $Z$s, $Y$s or $X$s in the Gauss graph operator. There is a natural extension to include operators, suggested by this identification. For example

$$\text{Tr}(Y \frac{d}{dZ})^{k_1} \text{Tr}(X \frac{d}{dZ})^{k_2} \leftrightarrow (a_y^\dagger)^{k_1} (a_x^\dagger)^{k_2} (a_z)^{k_1+k_2} \quad (3.7)$$

As a test of the proposed correspondence, note that

$$\langle O_{n-k_1-k_2,m+k_1,p+k_2} | (a_y^\dagger)^{m+k_1} (a_x^\dagger)^{p+k_2} (a_z^\dagger)^{n+k_1} (a_z)^{p+k_2} |0\rangle = \langle 0 | (a_z)^n (a_y)^{m+k_1} (a_x^\dagger)^{p+k_2} (a_z^\dagger)^{n+k_1} (a_x^\dagger)^{p+k_2} |0\rangle \quad \frac{1}{\sqrt{n!m!p!(n-k_1-k_2)!(m+k_1)!(p+k_2)!}}$$

which is in complete agreement with (3.4). Very similar computations comparing, for example

$$\langle O_{n-k_1,m-k_2,p-k_3}^\dagger \left( \text{Tr} \frac{d}{dZ} \right)^{k_1} \left( \text{Tr} \frac{d}{dY} \right)^{k_2} \left( \text{Tr} \frac{d}{dX} \right)^{k_3} O_{n,m,p} \rangle \quad (3.9)$$

and

$$\langle O_{n-k_1,m-k_2,p-k_3} | (a_z)^{k_1} (a_y)^{k_2} (a_x)^{k_3} |O_{n,m,p}\rangle \quad (3.10)$$

show that we should identify

$$a_x \leftrightarrow \sqrt{\frac{m+n+p}{N+m+n+p}} \text{Tr} \left( \frac{d}{dX} \right)$$

$$a_y \leftrightarrow \sqrt{\frac{m+n+p}{N+m+n+p}} \text{Tr} \left( \frac{d}{dY} \right)$$

$$a_z \leftrightarrow \sqrt{\frac{m+n+p}{N+m+n+p}} \text{Tr} \left( \frac{d}{dZ} \right) \quad (3.11)$$

These computations make use of the reduction rule of [27] [28].

We now want to argue that the identifications we have developed above have a natural extension which identifies Gauss graph operators with $q$ rows with a $q$ particle system.
Towards this end, we first point out a dramatic simplification in the formula for the Gauss graph operators, arising when we specialize to BPS operators. As discussed in the introduction, in this case we set the permutation $\sigma$ appearing in (1.1) to the identity. Using the orthogonality of the branching coefficients we then find

$$
\sum_{j,k} \Gamma (s,t)_{jk} (1) B_{jk \bar{\mu}_1}^{(s,t) \rightarrow 1 \eta X \times \eta Y} B_{k \bar{\mu}_2}^{(s,t) \rightarrow 1 \eta X \times \eta Y} = \sum_{j,k} \delta_{jk} B_{j \bar{\mu}_1}^{(s,t) \rightarrow 1 \eta X \times \eta Y} B_{k \bar{\mu}_2}^{(s,t) \rightarrow 1 \eta X \times \eta Y} = \delta_{\bar{\mu}_1 \bar{\mu}_2} \quad (3.12)
$$

This leads to the following formula (the operators below are normalized to have a unit two orthogonality of the branching coefficients we then find

$$
O_{R,r}^{\bar{\mu}}(X,Y,Z) = \frac{1}{n! m! p!} \sqrt{|H_X \times H_Y| \text{hooks}_R \text{hooks}_r \text{hooks}_f} \sum_{\sigma \in S_{n+m+p}} \text{Tr} \left( P_{R,r} \Gamma_R(\sigma) \right) \text{Tr}(\sigma X^{\otimes p} Y^{\otimes m} Z^{\otimes n})
$$

(3.13)

$P_{R,r}$ is a projector on the carrier space of $R$. It projects to the subspace of Young-Yammonouchi states that have $1, 2, ..., m + p$ distributed in the boxes that belong to $R$ but not $r$ and $m + p + 1, ..., m + p + n$ distributed in the boxes that belong to $R$ and $r$. Using this formula, it is straight forward to prove that

$$
\text{Tr} \left( \frac{d}{dX} \right) O_{R,r}^{\bar{\mu}}(X,Y,Z) = \sum_{i=1}^{q} \sqrt{\frac{p_i}{n_i + m_i + p_i}} c_{R_i R_i^{(1)}}^{(1)} O_{R_i^{(1)}, r_i^{(1)}}^{m_i, \bar{\mu}_i}(X,Y,Z) \quad (3.14)
$$

$$
\text{Tr} \left( \frac{d}{dY} \right) O_{R,r}^{\bar{\mu}}(X,Y,Z) = \sum_{i=1}^{q} \sqrt{\frac{m_i}{n_i + m_i + p_i}} c_{R_i R_i^{(1)}}^{(1)} O_{R_i^{(1)}, r_i^{(1)}}^{m_i, \bar{\mu}_i}(X,Y,Z) \quad (3.15)
$$

$$
\text{Tr} \left( \frac{d}{dZ} \right) O_{R,r}^{\bar{\mu}}(X,Y,Z) = \sum_{i=1}^{q} \sqrt{\frac{n_i}{n_i + m_i + p_i}} c_{R_i R_i^{(1)}}^{(1)} O_{R_i^{(1)}, r_i^{(1)}}^{m_i, \bar{\mu}_i}(X,Y,Z) \quad (3.16)
$$

The first formula above is exact. The last two hold only in the large $N$ limit. We have introduced some new notation: the Young diagram $R_i^{(n)}$ is obtained from $R$ by dropping $n$ boxes from row $i$ of $R$. Further, $\bar{\mu}_i^{(n)}$ is obtained from vector $\bar{\mu}$ by replacing $p_i \rightarrow p_i - n$ and similarly for $\bar{\mu}_i^{(n)}$. Finally, $c_{R R_i^{(1)}}$ is the factor of the box that belongs to $R$ but not to $R_i^{(1)}$. Recall that a box in row $i$ and column $j$ has factor $N - i + j$. For the proof of these formulas, we use the notation

$$
\mathcal{N} = \frac{1}{n! m! p!} \sqrt{|H_X \times H_Y| \text{hooks}_R \text{hooks}_r \text{hooks}_f R}
$$

and

$$
\text{Tr}(\sigma \cdot X^{\otimes p} \otimes Y^{\otimes m} \otimes Z^{\otimes n}) = X_{i_1}^{i_{\sigma(1)}} \cdots X_{i_p}^{i_{\sigma(p)}} Y_{i_{\sigma(p+1)}}^{i_{\sigma(p+1)}} \cdots Y_{i_{\sigma(p+m)}}^{i_{\sigma(p+m)}} Z_{i_{\sigma(p+m+1)}}^{i_{\sigma(p+m+1)}} \cdots Z_{i_{\sigma(p+m+n)}}^{i_{\sigma(p+m+n)}}
$$
We will now prove (3.14). A simple computation shows
\[
\frac{dO_{R,r}^{m,p}}{dX_i^j} = pN \sum_{\sigma \in S_{n+m+p}} \text{Tr}(P_{R,r} \Gamma^{(R)}(\sigma)) \text{Tr}(\sigma \cdot 1X^{\otimes p-1} \otimes Y^{\otimes m} \otimes Z^{\otimes n})
\]
\[
= pN \sum_{\sigma \in S_{n+m+p-1}} \sum_{i=1}^{n+m} \text{Tr}(P_{R,r} \Gamma^{(R)}(\sigma(i,1)) \text{Tr}(\sigma(i,1) \cdot 1X^{\otimes p-1} \otimes Y^{\otimes m} \otimes Z^{\otimes n})
\]
\[
= pN \sum_{\sigma \in S_{n+m+p-1}} \text{Tr}(P_{R,r} \Gamma^{(R)}(\sigma)[N + \sum_{i=2}^{n+m} (i,1)]) \text{Tr}(\sigma \cdot 1X^{\otimes p-1} \otimes Y^{\otimes m} \otimes Z^{\otimes n})
\]

Since we are summing over elements of the subgroup \(S_{n+m+p-1} \subset S_{n+m+p}\) we can decompose the trace over the irreducible representation of \(S_{n+m+p}\) as a sum of traces over irreducible representation \(R^{(1)}_i\) of the subgroup \(S_{n+m+p-1}\). Now use the fact that \(N + \sum_{i=2}^{n+m} (i,1)\) gives \(c_{RR^{(1)}}\) = the factor of the box dropped from \(R\) when acting on any state in the carrier space of \(R\) that also belongs to the \(R^{(1)}_i\) subspace. We find
\[
\frac{dO_{R,r}^{m,p}}{dX_j^j} = \sum_{i=1}^{q} f_N^{(i)} c_{RR^{(1)}_i} \frac{dO_{R^{(1)}_i,r}^{m,p}}{dX_j^j}
\]
where the factor
\[
f_N^{(i)} = \sqrt{\frac{p_i}{(n_i + m_i + p_i)c_{RR^{(1)}_i}}}
\]
accounts for the change in the normalization factor \(N\) of the operator. This is an exact formula - it does not depend on large \(N\) or on the displaced corners approximation.

Next consider the proof of (3.15) and (3.16). Consider
\[
\frac{dO_{R,r}^{m,p}}{dY_i^j} = mN \sum_{\sigma \in S_{n+m+p}} \text{Tr}(P_{R,r} \Gamma^{(R)}(\sigma)) \text{Tr}(\sigma \cdot X^{\otimes p} \otimes 1 \otimes Y^{\otimes m-1} \otimes Z^{\otimes n})
\]
\[
= mN \sum_{\sigma \in S_{n+m+p-1}} \sum_{i=1}^{n+m} \text{Tr}(P_{R,r} \Gamma^{(R)}(\sigma)) \text{Tr}((p+1,1) \sigma(p+1,1) \cdot 1 \otimes X^{\otimes p} \otimes Y^{\otimes m-1} \otimes Z^{\otimes n})
\]
\[
= mN \sum_{\sigma \in S_{n+m+p-1}} \text{Tr}(P_{R,r} \Gamma^{(R)}((1,p+1) \sigma)(1, p+1)) \text{Tr}(\sigma \cdot 1 \otimes X^{\otimes p} \otimes Y^{\otimes m-1} \otimes Z^{\otimes n})
\]
The new feature in the above derivation is the presence of the \((1,p+1) \in S_{n+m+p}\) factors needed to swap the removed \(Y\) box to the end of the row so that it can be removed, using the same manipulations as above. The evaluation of the action of these factors is most easily performed using Young’s orthogonal representation, which gives a rule for the action of adjacent permutations (i.e. permutations of the form \((i,i+1)\)) on Young-Yamanouchi (hereafter abbreviated YY) states. Let \(|Y\rangle\) denote a YY state, and let \(|Y(i \leftrightarrow i+1)\rangle\) denote
the YY state obtained by swapping boxes $i$ and $i+1$. A box in row $a$ and column $b$ has content given by $b-a$. Denote the content of the box in $|Y\rangle$ filled with $j$ by $c_j$. The rule is

$$(i, i+1)|Y\rangle = \frac{1}{c_i - c_{i+1}}|Y\rangle + \sqrt{1 - \frac{1}{(c_i - c_{i+1})^2}}|Y(i \leftrightarrow i+1)\rangle \quad (3.19)$$

This rule simplifies dramatically in the displaced corners limit, at large $N$. If the two boxes belong to the same row we find $(i, i+1)|Y\rangle = |Y\rangle$ and if not $(i, i+1)|Y\rangle = |Y(i \leftrightarrow i+1)\rangle$.

This is all that is needed to complete the proof of (3.15) and (3.16) and it proceeds exactly as for the first rule proved above. Note that because we used simplifications of the large $N$ limit, (3.15) and (3.16) are not exact statements but hold only at large $N$. The three statements derived above admit some natural generalizations. For example, we can consider tracing over a product of derivatives to obtain

$$\text{Tr} \left( \frac{d^k}{dX^k} \right) O_{R,r}^{\bar{m}\bar{p}}(X, Y, Z) = \sum_{i=1}^{q} \left( \frac{c_{RR(i)}^{(k)}}{n_i + m_i + p_i} \right)^{\frac{k}{2}} \prod_{a=0}^{k-1} \sqrt{p_i - a} \prod_{b=0}^{k-1} \sqrt{m_i - b} O_{R(r),r}^{(k)}(X, Y, Z) \quad (3.20)$$

There are obvious generalizations when we have a product of $Y$ or $Z$ derivatives. We could also allow more than one type of derivative in a given trace, for example (in what follows $k = k_1 + k_2$)

$$\text{Tr} \left( \frac{d^{k_1}}{dX^{k_1}} \frac{d^{k_2}}{dY^{k_2}} \right) O_{R,r}^{\bar{m}\bar{p}}(X, Y, Z) = \sum_{i=1}^{q} \left( \frac{c_{RR(i)}^{(k)}}{n_i + m_i + p_i} \right)^{\frac{k_1}{2}} \prod_{a=0}^{k_1-1} \sqrt{p_i - a} \prod_{b=0}^{k_2-1} \sqrt{m_i - b} O_{R(r),r}^{(k_1)\bar{m}(k_2)}(X, Y, Z) \quad (3.21)$$

By using these formulas for each trace successively, we can also easily evaluate expressions of this form

$$\text{Tr} \left( \frac{d^{k_1}}{dX^{k_1}} \frac{d^{k_2}}{dY^{k_2}} \right) \cdots \text{Tr} \left( \frac{d^{k_q}}{dZ^{k_q}} \right) O_{R,r}^{\bar{m}\bar{p}}(X, Y, Z) \quad (3.22)$$

To compare to a multi particle system of $q$ noninteracting particles, again in a 3-dimensional harmonic oscillator potential, we need to introduce $q$ copies of the oscillators $(I, J = 1, ..., q)$

$$[a_{z}^{(I)}, a_{z}^{(J)\dagger}] = [a_{y}^{(I)}, a_{y}^{(J)\dagger}] = [a_{x}^{(I)}, a_{x}^{(J)\dagger}] = \delta^{IJ} \quad (3.23)$$

one copy for each particle. Each Gauss graph operator $O_{R,r}^{\bar{m}\bar{p}}$ is specified by giving the number of $Z$ boxes $(r_i)$, $Y$ boxes $(m_i)$ and $X$ boxes $(p_i)$ in the $i$th row for $i = 1, ..., q$. The corresponding multi particle state is

$$|O_{R,r}^{\bar{m}\bar{p}}\rangle = \prod_{i=1}^{q} \frac{(a_{z}^{(I)}\dagger)^{r_i} (a_{y}^{(I)}\dagger)^{m_i} (a_{x}^{(I)}\dagger)^{p_i}}{\sqrt{r_i!} \sqrt{m_i!} \sqrt{p_i!}} |0\rangle \quad (3.24)$$
Using these formulas we can compare (for example) the matrix elements
\[
\langle O_{\vec{m}\vec{p}}^{R(k)}, r(q) | (a^{(I)}_z)^k | O_{\vec{m}\vec{p}}^{R,r} \rangle
\]
(3.25)
to the correlation functions
\[
\langle O_{\vec{m}\vec{p}}^{R(k), r(q)} | \left( \frac{d^k}{dZ^k} \right) O_{\vec{m}\vec{p}}^{R,r} \rangle
\]
(3.26)
to learn that we should identify
\[
\text{Tr} \left( \frac{d^k}{dZ^k} \right) \leftrightarrow \sum_{I=1}^q \left( \sqrt{\frac{N + m_I + n_I + p_I}{m_I + n_I + p_I}} \right)^k (a^{(I)}_z)^k
\]
(3.27)
In the above formula \( n_I \) is the number of \( Z \) boxes in row \( I \), \( m_I \) the number of \( Y \) boxes and \( p_I \) the number of \( X \) boxes. The general rule is \( k = k_1 + k_2 + k_3 \)
\[
\text{Tr} \left( \frac{d^{k_1}}{dX^{k_1}} \frac{d^{k_2}}{dY^{k_2}} \frac{d^{k_3}}{dZ^{k_3}} \right) \leftrightarrow \sum_{I=1}^q \left( \sqrt{\frac{N + m_I + n_I + p_I}{m_I + n_I + p_I}} \right)^k (a^{(I)}_x)^{k_1} (a^{(I)}_y)^{k_2} (a^{(I)}_z)^{k_3}
\]
(3.28)
It is easy to check that the ordering of operators inside the trace on the left hand side above does not matter, when acting on the operators we consider, at large \( N \). Multi trace formulas use the above identification for each trace separately. For example
\[
\text{Tr} \left( \frac{d^{k_1}}{dX^{k_1}} \frac{d^{k_2}}{dY^{k_2}} \frac{d^{k_3}}{dZ^{k_3}} \right) \text{Tr} \left( \frac{d^{k_4}}{dX^{k_4}} \right)
\]
\[
\leftrightarrow \sum_{I=1}^q \left( \sqrt{\frac{N + m_I + n_I + p_I}{m_I + n_I + p_I}} \right)^{k_4} (a^{(I)}_x)^{k_1} (a^{(I)}_y)^{k_2} (a^{(I)}_z)^{k_3}
\]
\[
\times \sum_{J=1}^q \left( \sqrt{\frac{N + m_J + n_J + p_J}{m_J + n_J + p_J}} \right)^{k_4} (a^{(J)}_x)^{k_4}
\]
(3.29)
By comparing overlaps between states with polynomials of creation and annihilation operators sandwiched in between and correlators of Gauss graph operators with traces of polynomials of the matrices and derivatives with respect to the matrices acting on the Gauss graph operators as in the examples we studied above, we can build any entry in the dictionary between the \( q \) particle system and Gauss graph operators with \( q \) rows.

## 4 Outlook

The description of giant gravitons, constructed using a world volume analysis, allows one to count the set of all \( \frac{1}{8} \)-BPS giant gravitons. This counting matches \( N \) bosons in a 3-dimensional harmonic oscillator. It is also possible to define an index to count single trace...
BPS operators, and it can be computed both at weak coupling (using the gauge theory) and at strong coupling (as a sum over the spectrum of free massless particles in AdS$_5 \times$S$^5$). The results of these different computations are in complete accord. One can compute the spectrum of anomalous dimensions, for operators with a bare dimension of order $N$, in the $\mathcal{N} = 4$ super Yang-Mills theory\cite{21, 22, 23}. In this study we have demonstrated that exactly the same counting (i.e. $N$ bosons in a 3-dimensional harmonic oscillator) results from counting operators of vanishing anomalous dimension in this spectrum. Motivated by this agreement, we have looked for a relation between multi particle wave functions and Gauss graph operators. Our basic result is that a map between particle wave functions for particles in a 3-dimensional harmonic oscillator and Gauss graph operators is easily constructed by comparing overlaps of wave functions of the particle system with correlators of Gauss graph operators. The correlator computations have made use of significant simplifications that arise for the BPS Gauss graph operators. The number of particles match the number of rows in the Young diagram labeling the Gauss graph operator. In our opinion, these results provide concrete evidence that the Gauss graph operators are indeed the operators dual to the $\frac{1}{8}$-BPS giant gravitons. To interpret the link between the particle system and the Gauss graph operators, recall the link between giant gravitons and an eigenvalue description of the multi matrix dynamics, which has been pursued in \cite{29, 30}. Thus, the fact that the matrix model computations appear to be related to the dynamics of non-interacting particles gives hints as to how matrix model dynamics may simplify, along the line of the proposals of \cite{31, 32, 33, 34}.
