Abstract

Background Inflammatory bowel disease (IBD) has a significant negative impact on quality of life (QOL); however, the direct impact of IBD on several aspects of patients’ lives is unknown. The IMPACT survey was conducted in Europe in 2010–2011 to determine this impact. We conducted the IMPACT survey in Japan and compared the results between subgroups of patients with ulcerative colitis (UC) and Crohn’s disease (CD).

Methods The 52-item IMPACT survey questionnaire assessing treatment and the impact of IBD on patients’ lives was translated into Japanese and administered to IBD patients recruited through patient advocacy groups.

Results Between June 2013 and January 2014, 172 Japanese IBD patients completed the questionnaire (including 84 UC and 83 CD patients). Half of all patients (84/172, 48.8 %) were satisfied with their treatment plan, and half of those who had undergone surgery were satisfied with the outcome (46/87, 52.9 %). Although 34.9 % (60/172) of patients had not been hospitalized in 5 years, 50.0 % (86/172) had been hospitalized for more than 10 days. During the most recent flare, 49.4 % (85/172) of patients had to reschedule appointments because of IBD. Moreover, 32.0 % (55/172) of patients had to make adjustments such as working part-time or at home to avoid taking sick days; 35.5 % (61/172) of patients felt that they had lost a job because of IBD.

Conclusions Our survey results indicate that IBD patients’ lives and social activities are affected by the deterioration of QOL due to IBD and its symptoms.

Keywords Inflammatory bowel disease · Quality of life · Ulcerative colitis · Crohn’s disease · Patient organization

Introduction

Inflammatory bowel disease (IBD) is a group of chronic and recurring inflammatory conditions of the intestine of unknown cause and primarily refers to ulcerative colitis (UC) and Crohn’s disease (CD). As of December 2014 in Japan, 170,781 patients with UC and 40,885 patients with CD were receiving treatment, and the number of patients with IBD is increasing [1]. Because these diseases are intractable and require long-term therapy, patients undergo not only physical strain but also deteriorated quality of life (QOL), both mentally and socially [2–5].

As the need for an appropriate QOL assessment for patients with IBD is increasing, a questionnaire survey of IBD patients, the IMPACT survey was conducted between 2010 and 2011 in 25 European countries under the initiative of the European Federation of Crohn’s and Ulcerative Colitis Associations (EFCCA) [6, 7]. The European
IMPACT survey studied IBD treatment and the impact of IBD on patients’ lives and social activities based on survey responses from 4670 patients with IBD.

Similar to the European IMPACT survey, we conducted a survey in Japan; the results are reported here. The aim of this survey was to investigate IBD treatment in Japan and the impact of IBD on patients’ lives and social activities. Also, we compared the results between the subgroups of patients with UC and patients with CD.

Methods

**IMPACT survey**

The questionnaire is a Japanese translation of the English version originally developed by the EFCCA and used in the European IMPACT survey (http://www.efcca.org/index.php/our-activities/ended-projects/51-join-the-fight-against-ibd-project). The English version of the European IMPACT survey questionnaire was developed by the EFCCA, with the support of AbbVie Inc. (North Chicago, IL, USA), and was reviewed by health informaticians. The Japanese translation was examined by one of the authors (F.U.) before its distribution to patients by mail and online.

The questionnaire consists of 52 questions divided into six categories: (1) your experience with IBD, (2) healthcare, (3) the impact that IBD has on your life, (4) overall work impact, (5) overall life impact, and (6) the role of patient organizations. Many of the questions were sourced from validated, published, and peer-reviewed academic surveys or from national IBD association surveys conducted in the past.

**Subjects and methods**

The questionnaire survey was conducted via mail or online with the support of the IBD Network, a patient association in Japan, during the period from 1 June 2013 to 31 January 2014. The answers were anonymous and the questionnaires were handled in such a way that personal information was not linked to patient data. Participants were required to be IBD patients, but were otherwise not excluded by any characteristics, such as age or sex. In most questions, participants were allowed to tick one applicable option.

The online survey recruited patients with IBD nationwide who belong to the IBD Network. The IBD Network posted the information on its website and distributed leaflets to its patient members to disseminate the survey information. To avoid duplication as much as possible, each participant was required to register his or her e-mail address; a website link was sent to guide the participant to the questionnaire form. The survey data were managed by the EFCCA. The paper survey was sent to 100 patients who belong to the IBD Network. Survey collection and aggregation were performed by Sunplanet Co., Ltd. (Tokyo, Japan). The surveys collected by Sunplanet were translated into English and sent to the EFCCA.

Data analysis was outsourced from the EFCCA to a research consultant, Survey Solutions Ltd. (Teddington, Middlesex, UK). The analysis results sent to the EFCCA were forwarded to us for interpretation. Each participant gave his or her permission to use the survey data for research and disclose the results after being notified of their complete anonymity.

Results

**Respondents**

Responses were obtained from 172 patients with IBD. Ninety-eight online and 74 paper surveys were collected; the retrieval rate was 74 % for the paper surveys. The respondents consisted of 84 patients with UC, 83 patients with Crohn’s disease, one patient with unclassifiable disease and four patients who did not answer this question (Table 1, Q1). In all, 114 participants were male and 55 were female; three participants did not answer this question. The majority of respondents (94 patients) were in the 35- to 54-year-old age group. Regarding disease activity, 79 patients (45.9 %) were in remission, 55 patients (32.0 %) were having periodic flare-ups and 20 patients (11.6 %) had chronically active disease (Table 1, Q16).

**Patient experience with IBD**

The time between noticing the first symptoms and receiving a final diagnosis was less than 6 months for 74 patients (43.0 %), representing the most common response. A final diagnosis was made within 1 year for 99 patients (57.6 %). Conversely, it took 5 years or longer to arrive at a final diagnosis for 31 patients (18.0 %) (Fig. 1, Q2). The time between noticing IBD-related symptoms and seeing an IBD specialist was less than 6 months for 77 patients (44.8 %), representing the most common response. The majority of patients (100 patients; 58.1 %) saw a specialist within 1 year (Fig. 2, Q3).

**Healthcare**

Among the respondents, 82 patients (47.7 %) did not have a history of surgery for IBD, while 24 patients (14.0 %) had undergone one surgery and 63 patients (36.6 %) had underwent two or more surgeries (Table S1, Q6). Regarding patient satisfaction with operative outcome, 46
patients were very or somewhat satisfied (Table 2, Q7), accounting for 52.9% of the 87 patients who underwent surgery at least once. Regarding hospitalisation in the past 5 years, 60 patients (34.9%) were not hospitalised at all, 36 patients (20.9%) spent 1–30 days in the hospital, 44 patients (25.6%) spent 31–100 days in the hospital and 20 patients (11.6%) had been hospitalised for more than 100 days (Table S1, Q8).

Aminosalicylates were the most commonly used medications; 131 patients (76.2%) were currently receiving aminosalicylates at the time of the survey and 26 patients (15.1%) had received aminosalicylates in the past. Regarding other concomitant medications, 28 patients (16.3%) were currently being treated with corticosteroids at the time of the survey and 94 patients (54.7%) had been treated with corticosteroids in the past; 45 patients (26.2%) were being treated with immunomodulators at the time of the survey and 33 patients (19.2%) had been treated with immunomodulators in the past; 58 patients (33.7%) were currently being treated with biologic drugs and 15 patients (8.7%) had been treated with biologic drugs in the past. There were eight patients (4.7%) who were not taking any medication at the time of the survey (Fig. 3, Q9).

Approximately half of the respondents were satisfied with their current IBD treatment plan; 24 patients (14.0%) were very satisfied and 60 patients (34.9%) were somewhat satisfied (Table 2, Q10). There were 147 patients (85.5%) who reported that they had access to a gastroen-

| No answer | 7 | 4.1 |
| Q14 Do you believe that you have adequate access to your IBD professional? For example, can you get an appointment to see your IBD healthcare professional on a timely basis? | | |
| Yes | 136 | 79.1 |
| No | 20 | 11.6 |
| Don’t know | 14 | 8.1 |
| No answer | 2 | 1.2 |
| Q15d Which professional(s) do you feel best understands the full picture of how IBD impacts your life—not just the medical problem? (Tick all that apply) | | |
| Applicable, No. (%) | Not applicable, No. (%) | No answer, No. (%) |
| Specialists/gastroenterologist | 107 (62.2) | 62 (36.0) | 3 (1.7) |
| General physician/clinic | 32 (18.6) | 137 (79.7) | 3 (1.7) |
| Nurse | 34 (19.8) | 135 (78.5) | 3 (1.7) |
| Counsellor or psychologist | 5 (2.9) | 164 (95.3) | 3 (1.7) |
| Other | 7 (4.1) | 162 (94.2) | 3 (1.7) |
| Don’t know/not applicable | 36 (20.9) | 133 (77.3) | 3 (1.7) |

IBD inflammatory bowel disease
After an appointment with a gastroenterologist, 118 patients (68.6%) sometimes (or more often) thought that the physician should have asked more probing questions to better understand their disease status (Table 2, Q12). In addition, 79 patients (45.9%) sometimes (or more often) felt that they did not get to tell the physician something potentially important about their IBD status (Table 2, Q13).

Among the respondents, 136 patients (79.1%) felt that access to their IBD professional was adequate (Table 2, Q14). In response to questions about communication with medical professionals, 114 patients (66.3%) answered that the best range of options for communication was available with an IBD specialist/gastroenterologist, 38 patients (22.1%) selected a nurse, 31 patients (18.0%) selected a general physician/clinic and one patient (0.6%) selected a counsellor (Q15a, data not shown). With regard to medical professionals who best understand not just the medical problems but also the entire picture of how IBD impacts their life, 107 patients (62.2%) chose an IBD specialist/gastroenterologist, 34 patients (19.8%) chose a nurse, 32 patients (18.6%) chose a general physician/clinic and five patients (2.9%) chose a counsellor (Table 2, Q15d).

**Impact that IBD has on your life**

During the current or most recent flare, 85 patients (49.4%) sometimes or more frequently had to cancel or reschedule an engagement or meeting because of IBD (Table 3, Q19). During the current or most recent period not experiencing a flare, 90 patients (52.3%) hardly ever/never had to cancel or reschedule an engagement or meeting because of IBD, and 50 patients (29.1%) had to sometimes or more frequently cancel or reschedule an engagement or meeting because of IBD (Table S2, Q27).

During the current or most recent flare, 84 patients (48.8%) did not experience bleeding from the gastrointestinal tract and 84 patients (48.8%) experienced bleeding at least 1 day a week. Among those who experienced bleeding, 42 patients (24.4%) had bleeding every day (Table S2, Q20). During the current or most recent period not experiencing a flare, 136 patients (79.1%) did not experience bleeding from the gastrointestinal tract and 31 patients (18.0%) experienced bleeding at least 1 day a week. Among those who experienced bleeding, seven patients (4.1%) had bleeding every day (Table S2, Q28).

During the current or most recent flare, 51 patients (29.7%) did not experience cramping pain in the abdomen and 116 patients (67.4%) experienced abdominal pain at least 1 day a week. Of the patients experiencing abdominal pain, 57 patients (33.1%) experienced abdominal pain every day (Table S2, Q21). During the current or most recent period not experiencing a flare, 99 patients (57.6%) did not experience cramping pain in the abdomen and 69 patients (40.1%) experienced abdominal pain at least 1 day a week. Of the patients experiencing abdominal pain, 12 (7.0%) experienced abdominal pain every day (Table S2, Q29).

During the current or most recent flare, 40 patients (23.3%) did not feel tired, weak or worn out and 129
Table 3  Impact of IBD on work and life \((N = 172)\)

| Q18 How many flare-ups would you say you have experienced in the last 2 years? | No. | % |
|---|---|---|
| 0 (None) | 56 | 32.6 |
| 1 | 33 | 19.2 |
| 2 | 25 | 14.5 |
| 3 | 17 | 9.9 |
| 4 | 5 | 2.9 |
| 5 | 5 | 2.9 |
| 6 | 1 | 0.6 |
| 7 | 0 | 0.0 |
| 8 | 0 | 0.0 |
| 9 | 0 | 0.0 |
| 10 | 1 | 0.6 |
| More than 10 | 4 | 2.3 |
| My condition is always (chronically) actively flaring | 20 | 11.6 |
| No answer | 5 | 2.9 |

Q19 During your current or most recent flare, how often do/did you have to cancel or reschedule an engagement, meeting, etc. because of your IBD? (Select the option that most closely represents your own experience)

| Always (100 % of the time) | 12 | 7.0 |
| Most of the time (75–99 %) | 12 | 7.0 |
| Much of the time (50–74 %) | 24 | 14.0 |
| Sometimes (25–49 %) | 37 | 21.5 |
| Hardly ever/never (less than 25 % of the time) | 56 | 32.6 |
| Not applicable/don’t know | 27 | 15.7 |
| No answer | 4 | 2.3 |

Q36 Please indicate any adjustments you have made to your working life, purely to avoid the need to take sick days as a result of your IBD:

| No adjustment | 102 | 59.3 |
| Working flexible hours | 14 | 8.1 |
| Working from home | 17 | 9.9 |
| Working part-time | 24 | 14.0 |
| No answer | 15 | 8.7 |

Q38 If you have been absent from work due to your IBD, what was this primarily due to? (Tick all that apply)

| Reason | Applicable, No. (%) | Not applicable, No. (%) | No answer, No. (%) |
|---|---|---|---|
| Hospital/emergency department visit | 39 (22.7) | 116 (67.4) | 17 (9.9) |
| Doctor appointment | 87 (50.6) | 68 (39.5) | 17 (9.9) |
| Incontinence or fear of incontinence | 13 (7.6) | 142 (82.6) | 17 (9.9) |
| Cramping or painful abdomen | 40 (23.3) | 115 (66.9) | 17 (9.9) |
| Fear of toilet frequency interfering with work activities | 28 (16.3) | 127 (73.8) | 17 (9.9) |
| Fear of toilet frequency bringing attention to my condition from colleagues | 6 (3.5) | 149 (86.6) | 17 (9.9) |
| Fatigue and/or not enough energy to get through the day | 54 (31.4) | 101 (58.7) | 17 (9.9) |
| Worry about gas pressure, discomfort | 20 (11.6) | 135 (78.5) | 17 (9.9) |
| Worry/fear of potential for embarrassment | 7 (4.1) | 148 (86.0) | 17 (9.9) |
| Rectal/anal pain or burning | 8 (4.6) | 147 (85.5) | 17 (9.9) |
| Volume of blood in bleeding episode | 13 (7.6) | 142 (82.6) | 17 (9.9) |
| I have never been absent from work due to IBD | 8 (4.6) | 147 (85.5) | 17 (9.9) |
| Not applicable/other | 31 (18.0) | 124 (72.1) | 17 (9.9) |

*IBD* inflammatory bowel disease
patients (75.0 %) felt tired at least 1 day a week. Of the patients who felt tired, weak or worn out, 59 patients (34.3 %) felt tired every day (Table S2, Q22). During the current or most recent period not experiencing a flare, 69 patients (40.1 %) did not feel tired, weak or worn out and 99 patients (57.6 %) felt tired at least 1 day a week. Of the patients who felt tired, weak or worn out, 18 (10.5 %) felt tired every day (Table S2, Q30).

During the current or most recent flare, 56 patients (32.6 %) did not feel a sudden uncontrollable urge for a bowel movement and 113 patients (65.7 %) had bowel urgency at least 1 day a week. Of those experiencing bowel urgency, 49 patients (28.5 %) had bowel urgency every day (Table S2, Q23). During the current or most recent period not experiencing a flare, 91 patients (52.9 %) did not feel a sudden uncontrollable urge for a bowel movement and 77 patients (44.8 %) had bowel urgency at least 1 day a week. Of the patients experiencing bowel urgency, 14 (8.1 %) had bowel urgency every day (Table S2, Q31).

During the current or most recent flare, 26 patients (15.1 %) did not experience runny stools or an episode of diarrhoea and 128 patients (74.4 %) experienced diarrhoea at least once a day. Of the patients experiencing diarrhoea, 48 patients (27.9 %) had diarrhoea 5–10 times a day, representing the most common answer (Table S2, Q24). During the current or most recent period not experiencing a flare, 62 patients (36.0 %) did not experience runny stools or an episode of diarrhoea and 99 patients (57.6 %) experienced diarrhoea at least once a day. Of the patients experiencing diarrhoea, 44 (25.6 %) had diarrhoea one or two times a day, representing the most common answer (Table S2, Q32).

During the current or most recent flare, 69 patients (40.1 %) sometimes or more frequently had to abruptly stop or leave a conversation, meeting or activity because of symptoms of IBD (Table S2, Q25). During the current or most recent period not experiencing a flare, 36 patients (20.9 %) sometimes or more frequently had to abruptly stop or leave a conversation, meeting or activity because of symptoms of IBD (Table S2, Q25).

Eighty-one patients (47.1 %) felt that their lives were significantly or somewhat negatively affected by symptoms of IBD, even between flares (Table S2, Q26). During a period not experiencing a flare, 126 patients (73.3 %) worried sometimes or more frequently about when the next flare would occur. Of these patients, 35 (20.3 %) worried about the next flare all the time (Table S2, Q34).

Work impact

Regarding the overall work impact, 124 patients (72.1 %) feel stressed or pressured about taking sick time from work because of IBD (Table S2, Q35). Fifty-five patients (32.0 %) made adjustments in their working life to avoid taking sick days: 14 patients (8.1 %) work flexible hours, 17 patients (9.9 %) work from home and 24 patients (14.0 %) work part-time (Table 3, Q36). There were 111 patients (64.5 %) who had taken at least one sick day from work because of IBD in the past year; 25 patients (14.5 %) had been absent for more than 25 days (Table S2, Q37). The most common reasons for being absent from work were a doctor’s appointment (87 patients; 50.6 %), fatigue and/or not enough energy to get through the day (54 patients; 31.4 %), cramping or painful abdomen (40 patients; 23.3 %) and emergency department visits (39 patients; 22.7 %). Patients were also absent because of worries about symptoms instead of actually having symptoms, such as a fear of toilet frequency interfering with work (28 patients; 16.3 %) and worries about gas pressure or discomfort (20 patients; 11.6 %) (Table 3, Q38).

Forty-six patients (26.7 %) had received or heard complaints or unfair comments from superiors and/or colleagues about their work performance in relation to their illness (Table 3, Q39). Some felt they were discriminated in the workplace as a direct result of IBD (38 patients; 22.1 %) (Table 3, Q40). The most commonly reported impact of IBD on workplace behaviour was nonparticipation in work social activities (51 patients; 29.7 %), followed by less motivated at work (38 patients; 22.1 %), being quiet during meetings (24 patients; 13.5 %) and irritability at work (19 patients; 11.0 %). However, 46 patients (26.7 %) answered that their behaviours at work were unaffected by IBD (Table 3, Q41). As many as 79 patients (45.9 %) felt that IBD negatively affected their career path, opportunities for advancement, income and/or earning potential (Table 3, Q42). Sixty-one patients (35.5 %) felt that they had lost a job or had to quit a job because of IBD (Table 3, Q43).

Overall life impact

Regarding the impact of IBD on overall life, 44 patients (25.6 %) felt that IBD had prevented them from pursuing an intimate relationship, and 38 patients (22.1 %) felt that IBD had caused an intimate relationship to end. In addition, 40 patients (23.3 %) felt that IBD had prevented them from making and/or keeping friends (Table S3, Q44–46). Fifty-three patients (30.8 %) reported that IBD had negatively affected their ability to perform to their full potential in an educational setting (Table 3, Q47). In all, 108 patients (62.8 %) frequently considered the availability of toilets when planning to attend an event or meeting, 124 patients (72.1 %) worried about the ready availability of a toilet when going somewhere new, 30 patients (17.4 %) kept a list of clean, accessible toilets and considered it when leaving home, 58 patients (33.7 %) had to be rude to
people at times in order to gain access to a toilet to prevent
an accident, 10 patients (5.8 %) reported that other people
had sometimes joked about them when they urgently nee-
ded a toilet and 43 patients (25.0 %) frequently woke from
sleeping as a result of pain from IBD (Table S4, Q48).

The first time they met another person with IBD, 61
patients (35.5 %) felt more optimistic, positive and/or
hopeful about the future, 14 patients (8.1 %) felt more
pessimistic, negative and/or less hopeful about the future
and 88 patients (51.2 %) felt neither more optimistic nor
more pessimistic (Table S4, Q49).

The majority of the respondents (130 patients; 75.6 %)
were engaged in an IBD patient association (Table S4,
Q50); 73 patients (42.4 %) attend local or national patient
meetings, 108 patients (62.8 %) are members of their
national IBD association, 73 patients (42.4 %) receive
patient information leaflets from their national IBD asso-
ciation, 13 patients (7.6 %) call a helpline or e-mail their
national IBD association, 58 patients (33.7 %) subscribe to
newsletters or magazines from their national IBD associ-
ation, 39 patients (22.7 %) volunteer to help their national
IBD association, 13 patients (7.6 %) help their national
IBD association with fundraising, 38 patients (22.1 %)
became a leader or joined a committee within their national
IBD association and two patients (1.2 %) became an
EFCCA delegate or worked within an EFCCA project team
(Table S4, Q51). Among the respondents, 87 patients
(50.6 %) felt that being part of the patient association
improved their life in general as someone with IBD
(Table S3, Q52).

Subgroup analysis: ulcerative colitis vs. Crohn’s
disease

In a subgroup analysis, we compared the results between
respondents with UC (84 patients) and CD (83 patients).
Regarding disease activity, 38.1 % (32/84) and 55.4 % (46/83) of respondents, respectively, were in remission, 35.7 % (30/84) and 30.1 % (25/83) were having periodic flare-ups and 11.9 % (10/84) and 12.0 % (10/83) had chronically active disease. Table 4 shows the results of the questions for which the differences in the proportions between the two groups exceeded 20 %.

Patients with UC were diagnosed or visited a specialist
within a relatively short time after first noticing symptoms,
and patients with UC experienced more bleeding from the
gastrointestinal tract during a flare than patients with CD.
Forty-seven patients (56.0 %) with UC were diagnosed
within 6 months of first noticing symptoms, whereas this
was the case for only 27 patients (32.5 %) with CD (Table
4, Q2). Forty-nine patients (58.3 %) with UC saw a
specialist within 6 months of first noticing symptoms,
whereas this was the case for only 28 patients (33.7 %)
with CD (Table 4, Q3). During the current or most recent
flare, 35 patients (41.7 %) with UC had bleeding every day,
as opposed to seven patients (8.4 %) with CD (Table 4,
Q20). During the current or most recent period not expe-
rriencing a flare, 40 patients (47.6 %) with UC did not
experience runny stools or an episode of diarrhoea, as
opposed to 21 patients (25.3 %) with CD (Table 4, Q32).

Compared to patients with CD, patients with UC were more concerned about the side effects of steroids, and fewer patients with UC had a history of hospitalization or surgery. Forty-two patients (50.0 %) with UC were concerned about the long-term effects of steroids on their health, as opposed to 19 patients (22.9 %) with CD (Table 4, Q5-2). Regarding surgery, 64 patients (76.2 %) with UC and 17 patients (20.5 %) with CD had never undergone surgery; four patients (4.8 %) with UC had undergone five or more surgeries, as opposed to 15 patients (18.0 %) with CD (Table 4, Q6). Regarding hospitalization in the past 5 years, 39 patients (46.4 %) with UC and 21 (25.3 %) with CD had no hospital stays (Table 4, Q8). Regarding medications, fewer patients with UC were taking biologic drugs at the time of the survey compared to patients with CD (8.3 % [7/84] vs. 60.2 % [50/83]) (Table 4, Q9).

Patients with CD tended to have had a longer time since
their last flare at the time of the survey, though they also
seemed to feel more tired during the flare and have been
absent from work because of IBD more often. Forty-three
patients (51.8 %) with CD experienced their last flare more
than 1 year ago, compared to 24 patients (28.6 %) with UC
(Table 4, Q17). During the current or most recent flare, 39
patients (47.0 %) with CD felt tired every day, as opposed
to 20 patients (23.8 %) with UC (Table 4, Q22). Sixty-four
patients (77.1 %) with CD had taken at least one sick day
from work because of IBD in the past year, as opposed to
46 patients (54.8 %) with UC (Table 4, Q37).

Discussion

Our survey results indicate that the lives and social activ-
ities of patients with IBD are affected by the deterioration
of QOL due to IBD and its symptoms. In Japan, several
previous studies have also investigated QOL and the
impact of IBD on patients’ lives and social activities and
similarly demonstrated deterioration in QOL associated
with IBD [8–17]. Our present survey is unique in that we
used a questionnaire that comprised basically the same set
of questions as the European IMPACT survey to allow
direct comparison between the Japanese and European
survey results. Our survey results will not only help
improve medical treatment and care for patient with IBD in
Table 4  Comparison of ulcerative colitis and Crohn’s disease: the items for which the differences between the groups were more than 20 %

| Q2 How long after you first began to notice symptoms (that you now recognise as related to IBD) did it take to receive your final diagnosis? | Ulcerative colitis (N = 84) | Crohn’s disease (N = 83) |
|---------------------------------------------------------------|-----------------------------|--------------------------|
| No. (%)                                                       | No. (%)                     |
| Less than 6 months                                           | 47 (56.0)                   | 27 (32.5)                |
| 6 months–1 year                                              | 12 (14.3)                   | 12 (14.5)                |
| Over 1 to 5 years                                            | 14 (16.7)                   | 23 (27.7)                |
| Over 5 to 10 years                                           | 2 (2.4)                     | 10 (12.0)                |
| More than 10 years                                           | 8 (9.5)                     | 11 (13.3)                |
| Not applicable                                               | 1 (1.2)                     | 0 (0.0)                  |

| Q3 How long after your IBD-related symptoms began did it take for you to first see a specialist (e.g. gastroenterologist, nurse, IBD specialist) who was familiar with IBD? | Ulcerative colitis (N = 84) | Crohn’s disease (N = 83) |
|---------------------------------------------------------------|-----------------------------|--------------------------|
| No. (%)                                                       | No. (%)                     |
| Less than 6 months                                           | 49 (58.3)                   | 28 (33.7)                |
| 6 months–1 year                                              | 11 (13.1)                   | 12 (14.5)                |
| Over 1 to 5 years                                            | 18 (21.4)                   | 27 (32.5)                |
| Over 5 to 10 years                                           | 3 (3.6)                     | 11 (13.3)                |
| More than 10 years                                           | 2 (2.4)                     | 4 (4.8)                  |
| Not applicable                                               | 1 (1.2)                     | 1 (1.2)                  |

Japan but also provide useful information for reviewing medical practice for IBD in each country in Europe.

Our study results were similar to those of the European IMPACT survey for most components, including the time to definitive diagnosis, use of medications and life impact of IBD [6, 7]. Despite differences in race, life environment and medical system, the results of our study and the European IMPACT study likely reflect common trends in IBD patients. As in the European IMPACT study, the Japanese survey points out several issues: (1) communication between medical specialists and patients can be further improved, (2) IBD patients often have to take sick days from work and have psychological fear at work because of their illness, (3) IBD has a significant impact on daily life, including constant concern about toilets and difficulty building intimate relationships, and (4) IBD interferes with learning. Patients with IBD have unmet needs; the goal is to improve medical care and the social support system for patients with IBD in Japan.

While the Japanese results were generally similar to the European survey results [6], there were several differences. First, the proportion of patients who were somewhat or very satisfied with the outcomes of IBD-related surgical operations was lower in Japan (52.9 %) than in Europe (72.9 %). This may be partly attributed to the higher percentage of Japanese patients with surgical complications (20.3 %) compared with European patients (14.6 %). In addition, Japanese patients were less satisfied with their current treatment plan for IBD than European patients (48.8 vs 70.3 %). Because the answers to questions about the adequateness of communication with medical professionals were similar between Japanese and European patients, the lower level of satisfaction in Japanese patients cannot be attributed solely to inadequate communication,

Table 4 continued

| Q17 When was your last flare (before this one if you are currently experiencing one)? | No. (%) | N (%) |
|---|---|---|
| Less than 6 months ago | 27 (32.1) | 20 (24.1) |
| Over 6–12 months ago | 10 (11.9) | 8 (9.6) |
| More than 12 months ago | 24 (28.6) | 43 (51.8) |
| Not applicable | 23 (27.4) | 12 (14.5) |

| Q20 During your current or most recent flare, how many days in a week do/did you experience bleeding from your gastrointestinal tract? | No. (%) | N (%) |
|---|---|---|
| 0 day | 30 (35.7) | 53 (63.9) |
| 1–3 days | 13 (15.5) | 19 (22.9) |
| 4–6 days | 6 (7.1) | 2 (2.4) |
| 7 days | 35 (41.7) | 7 (8.4) |
| Not applicable | 0 (0.0) | 2 (2.4) |

| Q22 During your current or most recent flare, how many days in a week do/did you feel tired, weak or worn out? | No. (%) | N (%) |
|---|---|---|
| 0 day | 23 (27.4) | 17 (20.5) |
| 1–3 days | 29 (34.5) | 16 (19.3) |

*IBD* inflammatory bowel disease
indicating the presence of some other issue with the medical treatment itself or the medical environment in Japan.

Although a greater percentage of Japanese patients had not been hospitalised in the past 5 years compared with European patients (34.9 vs 15.4 %), more Japanese patients had been hospitalised for more than 10 days compared with European patients (50.0 vs 2.1 %). In addition, 11.6 % of Japanese patients remained in the hospital for more than 100 days, indicating that Japanese patients, once hospitalised, tend to remain in the hospital longer or return frequently.

Regarding healthcare professionals who are available for communication or who have the greatest influence on IBD patients, fewer Japanese patients named a counsellor or clinical psychologist compared with European patients. This indicates that counsellors and clinical psychologists are not sufficiently positioned in Japanese hospitals or are not adequately involved with patients with IBD. As shown in our survey results, IBD patients suffer a great deal of mental strain from their illness; thus, we will have to reconsider how counsellors and clinical psychologists can be involved in their care.

Finally, slightly more Japanese patients with IBD seem to feel stressed or pressured about taking sick time from work because of IBD compared with European patients (72.1 vs 60.5 %). Because Japanese patients do not seem to have particularly high external pressure, such as unfair treatment, discrimination and career path impediment due to IBD, Japanese patients may be too self-critical compared with European patients. Therefore, mental support will be necessary to promote the social participation of patients with IBD in Japan.

Subgroup analysis comparing UC and CD revealed characteristics of each disease based on the differences between the subgroups. UC is associated with more frequent anaemia, bloody stool, and mucous and bloody stool compared with CD, for which the frequency of bloody stool is less frequent. This is attributed to the characteristics of CD, in which lesions do not easily bleed and the rectum is less frequently affected. Thus, the present study results are consistent with the pathology of these conditions [18]. Patients with UC tend to develop intestinal haemorrhage on a daily basis during flare-ups, and many of them visited a specialist and received a definitive diagnosis at a relatively early phase. As described above, this is due to the pathological characteristics of UC, with patients having bloody stool and mucous and bloody stool more often compared with CD. On the other hand, patients with CD tend to have more adverse influences in their daily lives, such as absence from work, which seems to be due to malaise during flare-ups. However, the duration of a flare-up was not long in many patients. UC affects areas near the intestinal lumen, from the mucosal layer to the submucosal layer, representing shallow inflammation. In contrast, CD causes deeper inflammation, often reaching the muscle layer. UC, with shallower inflammation, is generally acknowledged as a milder enterocolitis than CD, which causes deeper inflammation. Thus, CD has a greater impact on labour productivity compared with UC, from a pathological point of view [19–21].

With regard to the therapy, many patients with UC expressed concern about the long-term use of steroids, while the majority of patients with CD received aggressive therapy, including hospitalization, surgical intervention and treatment with biological agents. This reflects the current UC treatment practice that frequently recommends steroids as part of remission induction therapy according to clinical practice guidelines (Japan, USA and EU) [22–24]. It should be noted that steroids are not suitable for maintenance therapy but are highly effective in remission induction. In the real world, patients with steroid dependency are treated with steroids for an extended period, and the associated adverse reactions are a concern [25, 26].

Although our survey offers a broad perspective, there are several limitations to this study. First, the survey participation was free and therefore it was inherently associated with a bias in respondent selection. Second, while not all respondents were attending patient associations, survey recruitment was conducted only within the reach of information from the IBD Network patient association and the respondents may not include those who were not closely related with that association. Third, the majority of respondents were acquired through the online survey site, and the results may not represent those who do not have access to the Internet. Fourth, the Japanese survey sample size was smaller than that of the European IMPACT survey. However, our survey achieved the minimum target of 100, which was also the target in the European survey [6]. Finally, several questions may have had a recall bias, as patients had to recall situations in the past.

Accessibility to the Internet or the IBD network may vary depending upon a patient’s awareness of treatment options and their environment; therefore, our survey may not necessarily reflect the current status of Japanese patients with IBD. Providing patients with a questionnaire during their medical visits, i.e. administering the survey via a healthcare professional, would better reflect their current situation across a broader demographic.

Conclusions

Our survey results indicate that lives and social activities of IBD patients in Japan are affected by the deterioration of QOL due to IBD and its symptoms. Information on the unmet needs of Japanese patients with IBD may help to
provide sufficient medical and administrative support, improve working and educational environments, and increase the awareness of healthcare providers in order to bridge communication gaps between patients and physicians.

Acknowledgments The authors would like to thank all of the patients and investigators who participated in the survey. AbbVie participated in the interpretation of data, review and approval of the publication. The financial support for the survey was provided by AbbVie. We would like to thank Mr. Imai, employees of AbbVie, who provided information about the IMPACT survey in Japan to patients with IBD. Sunplanet Co., Ltd. received a grant from AbbVie to collect and summarize the survey results. The survey summary was translated into English, was sent to the EFCCA and was analysed by research consultants [Ms. Johanna Ikonen (statistician) and Ms. Sanna Lönnfors (medical writer)] trusted by EFCCA; the analysis results were sent back to our team in Japan. AbbVie has made a donation to the EFCCA as a part of the financial support for the IMPACT survey in Japan. Ms. Kae Uetani of Statcom Co., Ltd. (Tokyo, Japan) provided medical writing and editing services in the development of this manuscript. AbbVie provided funding to Statcom Co., Ltd., for this work.
