Abstract

For integrable inhomogeneous supersymmetric spin chains (generalized graded magnets) constructed employing \( Y(gl(N|M))\)-invariant \( R\)-matrices in finite-dimensional representations we introduce the master T-operator which is a sort of generating function for the family of commuting quantum transfer matrices. Any eigenvalue of the master T-operator is the tau-function of the classical mKP hierarchy. It is a polynomial in the spectral parameter which is identified with the 0-th time of the hierarchy. This implies a remarkable relation between the quantum supersymmetric spin chains and classical many-body integrable systems of particles of the Ruijsenaars-Schneider type. As an outcome, we obtain a system of algebraic equations for the spectrum of the spin chain Hamiltonians.

1 Introduction and conclusion

Supersymmetric extensions of quantum integrable spin chains were introduced in [1, 2]. Such models, called graded magnets in [2], are based on solutions of the graded Yang-Baxter equation (graded analogues of quantum $R$-matrices) in the same way as ordinary integrable spin chains are built from quantum $R$-matrices satisfying the Yang-Baxter $R R R = R R R$ relation. An important class of solutions are $Y(gl(N|\mathcal{M}))$-invariant $R$-matrices taken in finite-dimensional representations which are simple rational functions of the spectral parameter $x$:

$$R(x) = 1 \otimes 1 + \frac{\eta}{x} P. \tag{1.1}$$

Here $P \in \text{End}(\mathbb{C}^{N|M} \otimes \mathbb{C}^{N|M})$ is the graded permutation operator. In this paper, we focus on graded magnets constructed using the $R$-matrices from this class. They are called (generalized) supersymmetric spin chains of the XXX type, or simply susy-XXX spin chains. Their trigonometric analogue is known as the Perk-Schultz model [3].

For our purpose we need inhomogeneous susy-XXX spin chains or the corresponding integrable lattice models of statistical mechanics on inhomogeneous lattices, with quasiperiodic (twisted) boundary conditions. Their quantum monodromy matrices $S(x)$ are products of the type

$$S(x) = R^{0L}(x-x_L) \ldots R^{02}(x-x_2)R^{01}(x-x_1)(g \otimes 1^{\otimes L}) \tag{1.2}$$

along the chain, with $x_i$ being inhomogeneity parameters assumed to be distinct and $g \in GL(N|M)$ being the twist matrix assumed to be diagonal. (The label 0 corresponds to the auxiliary space, where the product is taken.) The supertrace $T(x) = \text{str}_0 S(x)$ of the quantum monodromy matrix in the auxiliary space is what is called the quantum transfer matrix or the T-operator. The graded Yang-Baxter equation implies that the T-operators commute for all $x$, so $T(x)$ is a generating function of commuting Hamiltonians $H_j$:

$$T(x) = \text{str} g \cdot 1^{\otimes L} + \sum_{j=1}^{L} \frac{\eta H_j}{x-x_j}. \tag{1.3}$$

These Hamiltonians are non-local, i.e., involve interaction between operators on all lattice sites. However, such models still make sense as generalized spin chains with long-range interactions. Alternatively, one may prefer to keep in mind integrable lattice models of statistical mechanics rather than spin chains as such. In either case the final goal of the theory is diagonalization of the T-operators. This is usually achieved by the Bethe ansatz method in one form or another. What we are going to do in this paper is to suggest an alternative approach based on a hidden connection with classical many-body integrable systems explained below.

As an intermediate step, we need to recall that there exists a broader family of commuting T-operators which includes $T(x)$ as a subset. Using the fusion procedure in the auxiliary space, one can construct an infinite family of commuting T-operators $T_{\lambda}(x)$ indexed by Young diagrams $\lambda$, with $T_{\square}(x) = T(x)$. Following [4], we construct the master T-operator as their generating (operator-valued) function of a special form. Let $t = \{t_1, t_2, t_3, \ldots\}$ be an infinite set of auxiliary “time variables” and $s_{\lambda}(t)$ be the
Schur polynomials. The master T-operator, \( T(x, t) \), for graded magnets\(^1\) is introduced in the same way as in [4] and subsequent works [6]–[9]:

\[
\frac{T(x, t)}{T(x, 0)} = \sum_{\lambda} T_\lambda(x) s_\lambda(t). \tag{1.4}
\]

By construction, this family of operators is commutative for all \( x, t \) and can be simultaneously diagonalized:

\[
T(x, t) \ket{\Psi} = T(x, t) \ket{\Psi}.
\]

The main fact about the master T-operator, which makes the whole construction interesting, is that the so defined \( T(x, t) \) satisfies the bilinear identity for the classical modified Kadomtsev-Petviashvili (mKP) hierarchy, with \( x \) being identified with the “0th time” \( t_0 \):

\[
\oint_C z^{(x-x')/\eta} e^{\sum_{k \geq 1}(t_k - t'_k)z^k} T(x, t - [z^{-1}]) T(x', t' + [z^{-1}]) dz = 0 \tag{1.5}
\]

for all \( t, t', x, x' \) and for a properly chosen integration contour. Here \( \eta \pm [z^{-1}] := \{ t_k \pm \frac{1}{\eta} z^{-k} \} \). This means that any eigenvalue \( T(x, t) \) of \( T(x, t) \) is a tau-function of the mKP hierarchy. In this way, the commutative algebras of susy-XXX spin chain Hamiltonians, for all possible gradings, appear to be embedded into the infinite integrable hierarchy of non-linear differential-difference equations, the mKP hierarchy [10, 11, 12]. This is a further development of the earlier studies [13, 14, 15] clarifying the role of classical integrable hierarchies in quantum integrable models.

The next step depends on analytical properties of the eigenvalues \( T(x, t) \) as functions of the variable \( x \). For finite spin chains each eigenvalue is a polynomial in \( x \) of degree \( L \) for any \( t \):

\[
T(x, t) = e^{\text{str} \xi(t, g)} \prod_{j=1}^{L} (x - x_j(t)). \tag{1.6}
\]

The roots depend on the times \( t \). At this point, a surprising link to integrable many-body systems of classical mechanics comes into play. Namely, from the fact that \( T(x, t) \) is a tau-function of the mKP hierarchy it follows [16, 17] that the roots \( x_i \) move in the times \( t_k \) as particles of the Ruijsenaars-Schneider (RS) \( L \)-body system [18] subject to the equations of motion corresponding to the \( k \)th Hamiltonian \( H_k \) of the RS model. For example, the equations of motion for the \( t = t_1 \) flow are

\[
\ddot{x}_i = -\sum_{k \neq i} \frac{2\eta^2 \dot{x}_i \dot{x}_k}{(x_i - x_k) [(x_i - x_k)^2 - \eta^2]}, \quad i = 1, \ldots L. \tag{1.7}
\]

This link prompts to reformulate the spectral problem for the susy-XXX spin chain Hamiltonians \( H_j \) in terms of the integrable model of classical mechanics. It is important to stress that this quantum-classical correspondence (the QC-correspondence) does not depend on the choice of the grading; all graded magnets are linked to the same RS system of particles. The role of the QC-correspondence in supersymmetric gauge theories and branes was discussed in [19, 20, 21].

The RS system is often referred to as an integrable relativistic deformation of the famous Calogero-Moser system. Similarly to the latter, it admits the Lax representation, i.e. the dynamics can be translated into isospectral deformations of a matrix

\(^1\)A preliminary form of the master T-operator for these models appeared in the earlier work [5].
which is called the Lax matrix. The essence of the QC-correspondence of integrable systems lies in the fact that the spectra of the quantum Hamiltonians \( H_j \) are encoded in the Lax matrix \( Z(\{x_i(0)\}, \{\dot{x}_i(0)\}) \equiv Z_0 \) for the RS system at \( t = 0 \) after the identifications \( x_i(0) := x_i \) (the inhomogeneity parameters of the spin chain) and \( -\eta \dot{x}_i(0) := H_i \) (the eigenvalues of the quantum Hamiltonians):

\[
(Z_0)_{ij} = \frac{\eta H_i}{x_j - x_i + \eta}.
\]

Given the \( x_i \)'s, possible values of the \( H_i \)'s are determined from the condition that the matrix \( Z_0 \) has a prescribed set of eigenvalues which is a subset of \( \{g_1, g_2, \ldots, g_{N+M}\} \), where \( g_i \) are elements of the (diagonal) twist matrix \( g \), taken with certain multiplicities. In this way the spectral problem for the quantum Hamiltonians is reduced to a sort of inverse spectral problem for the Lax matrix.

We give two different proofs of this remarkable correspondence. One (indirect) is through the mKP hierarchy and its polynomial solutions. The other proof (based on the technique developed in [21]) is by a direct computation using the description of the spectrum in terms of the (nested) Bethe ansatz equations. Both proofs are rather technical. It is of value to find a more conceptual proof.

As a corollary, computing the spectral determinant for the RS Lax matrix, we find that the eigenvalues of the quantum Hamiltonians for all XXX spin chains on \( L \) sites are encoded in the following system of algebraic equations:

\[
\sum_{1 \leq i_1 < \ldots < i_n \leq L} H_{i_1} \ldots H_{i_n} \prod_{1 \leq \alpha < \beta \leq n} \left( 1 - \frac{\eta^2}{(x_{i_\alpha} - x_{i_\beta})^2} \right)^{-1} = e_n(g_1, \ldots, g_L), \quad n = 1, \ldots, L.
\]

Here \( e_n \) are elementary symmetric polynomials of \( L \) parameters \( g_i \): \( e_1 = \sum_i g_i, \quad e_2 = \sum_{i<j} g_i g_j, \) etc. Identifying them with elements of the twist matrix in a proper way (at \( L > N + M \) some \( g_i \)'s have to be merged), one finds a part of the spectrum \( (H_1, \ldots, H_L) \) for a particular spin chain among solutions to the system. Other solutions of the same system correspond to some other spin chain. In order to find the full spectrum of a given model, one should solve systems of the form (1.9), where \( g_i \)'s are taken with different possible multiplicities from a given set. Two points are worth emphasizing:

- These are equations for the spectrum itself, not for any auxiliary parameters like in the Bethe ansatz solution.
- This system does not depend on the grading, so the set of its solutions contain spectra of quantum Hamiltonians for the models with all possible gradings.

The detailed structure of solutions and their precise correspondence with spectra of particular spin chains is a subject of further study.

From the algebro-geometric point of view, equations (1.9) define a \( 2L \)-dimensional algebraic variety \( S_L \) which can be called the universal spectral variety for spin chains of the XXX type. It contains a comprehensive information about spectra of spin chains on \( L \) sites based on the \( gl(N|M) \) algebras with all possible gradings. The variety \( S_L \) given
by equations (1.9) is not compact. These equations only define its affine part embedded into the $3L$-dimensional space with coordinates $(H_1, \ldots, H_L; x_1, \ldots, x_L; g_1, \ldots, g_L)$. Presumably, a proper compactification of the universal spectral variety encodes information about the spectra of homogeneous spin chain Hamiltonians (when $x_i \to 0$).

Lastly, we would like to point out some unsolved problems and directions for further research.

a) The properly taken limit $\eta \to 0$ should lead to the similar QC correspondence between graded quantum Gaudin models and classical Calogero-Moser systems. This is technically involved but rather straightforward procedure. The details will be published elsewhere.

b) A less straightforward but quite realistic program is the extension to the models based on trigonometric solutions to the (graded) Yang-Baxter equation (the graded XXZ magnets and corresponding vertex models of statistical mechanics). As the results of [1] suggest, one can expect the trigonometric RS model on the classical side of the QC correspondence. The precise relation between eigenvalues of the Lax matrix and the twist parameters of the spin chain is to be elaborated.

c) The extension to quantum integrable models with elliptic $R$-matrices is problematic. Conceivably this might require new ideas. At the same time, the most natural candidate for the classical part of the QC correspondence is the elliptic RS model. The role of the spectral parameter which enters its Lax matrix is to be clarified.

d) There is a well-known duality [22, 23] of the classical RS (and Calogero-Moser) type models when the action variables in a given system are treated as coordinates of particles in the dual one. Equivalently, the soliton-like tau-function whose zeros move as the RS particles becomes the spectral determinant for the dual system and vice versa. An interesting future perspective is to realize the meaning of this duality in the context of quantum spin chains. Presumably, this duality implies some correspondence between spectra of different spin chains.

**Organization of the paper.** In Section 2 we recall the construction of the integrable susy-XXX spin chains starting from the quantum $R$-matrices. For our purpose we need a fully inhomogeneous model with twisted boundary conditions. We introduce the nonlocal commuting Hamiltonians, which are the main observables in the system, and such attendant objects like the higher T-operators (transfer matrices). The master T-operator is introduced in section 2.4 as their generating function. In section 2.5 we present the bilinear identity satisfied by the master T-operator which makes it possible to embed the quantum stuff into the context of classical integrable hierarchies of non-linear PDE’s. In particular, we define the classical Baker-Akhiezer function in terms of the quantum T-operators.

In Section 3 we establish and exploit the link to the RS $L$-body system. The main point here is the reformulation of the eigenvalue problem for the spin chain Hamiltonians in terms of coordinates and velocities of the RS particles. The Lax pair for the RS system is derived from the poles dynamics of the Baker-Akhiezer function in Section 3.2.
Section 4 contains some details of the QC correspondence which is based on the identification of the twist parameters with eigenvalues of the Lax matrix for the RS model (Section 4.1). In Section 4.3 the algebraic equations for eigenvalues of the spin chain Hamiltonians are obtained and the notion of the universal spectral variety is introduced. In Section 5 we give a direct proof of the QC correspondence, using the nested Bethe ansatz solution.

There are also three appendices. In Appendix A we give some technical details needed for deriving the higher T-operators in a more or less explicit form as derivatives of supercharacters. Appendix B is a reference source for the Hamiltonian approach to the RS system. Explicit examples of spin chain spectra for small number of sites ($L = 1, 2, 3$) and their comparison with solutions to the algebraic equations from Section 4.3 are given in Appendix C.

Zotov is supported in part by RFBR grant 14-01-00860, by the D. Zimin’s fund “Dynasty” and by the Program of RAS “Basic Problems of the Nonlinear Dynamics in Mathematical and Physical Sciences” Π19.

**The notation.** Throughout the paper, we use the following notation.

- $\mathcal{B}$: the set $\mathcal{B} = \{1, 2, \ldots, N\}$
- $\mathfrak{F}$: the set $\mathfrak{F} = \{N + 1, N + 2, \ldots, N + M\}$
- $p$: the $\mathbb{Z}_2$-grading parameter, $p(a) = 0$ for $a \in \mathcal{B}$ and $p(a) = 1$ for $a \in \mathfrak{F}$
- $e_{ab}$: generators of $\mathfrak{gl}(N|M)$ identified with (super)matrix units, $(e_{ab})_{a'b'} = \delta_{aa'}\delta_{bb'}$
- $v_a$: orthonormal basis vectors in $\mathbb{C}^{N|M}$ such that $e_{ab}v_c = \delta_{bc}v_a$, $p(v_a) = p(a)$
- $g$: a diagonal group element of $GL(N|M)$, $g = \text{diag}(g_1, \ldots, g_N, g_{N+1}, \ldots, g_{N+M})$
- $\lambda$: a Young diagram with rows $\lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_\ell > 0$
- $\lambda'$: the transposed Young diagram ($\lambda$ reflected in the main diagonal)
- $1$: the identity element in $\text{End}(\mathbb{C}^{N|M})$ or $\text{End}(\mathbb{C}^L)$
- $I$: the identity operator in the tensor product spaces like $(\mathbb{C}^{N|M})^\otimes L$, etc
- $O$: an operator in $(\mathbb{C}^{N|M})^\otimes L$ or $\mathbb{C}^L \otimes (\mathbb{C}^{N|M})^\otimes L$
- $O(x)$: an operator-valued rational function of $x$
- $O(x)$: an operator-valued polynomial function of $x$
The $\mathbb{Z}_2$-grading of the $gl(N|M)$-generators $e_{ab}$ (identified with the matrix units) is defined as $p(e_{ab}) = p(a) + p(b) \mod 2$. The commutation relations obeyed by the generators are $e_{ab}e_{cd} - (-1)^p(e_{ab})p(e_{cd}) e_{cd}e_{ab} = \delta_{bc}e_{ad} - (-1)^p(e_{ab})p(e_{cd})\delta_{ad}e_{cb}$.

Any tensor product in this paper is the $\mathbb{Z}_2$-graded one. Namely, for any homogeneous operators $\{A_i\}_{i=1}^4$ the tensor product satisfies the relation $(A_1 \otimes A_2)(A_3 \otimes A_4) = (-1)^{p(A_2)p(A_3)}(A_1A_3 \otimes A_2A_4)$.

We use the notation $\prod_{j=1}^L O_j = O_1O_2\ldots O_L$ and $\prod_{j=1}^L O_j = O_L\ldots O_2O_1$ for the ordered product of the operators $\{O_j\}_{j=1}^L$.

## 2 The master T-operator for supersymmetric spin chains

### 2.1 Quantum $R$-matrices

The simplest $Y(gl(N|M))$-invariant $R$-matrix has the form

$$R(x) = 1 \otimes 1 + \frac{\eta}{x} \sum_{a,b=1}^K (-1)^{p(b)}e_{ab} \otimes e_{ba}. \quad (2.1)$$

Hereafter, we set $K \equiv N + M$. The variable $x$ is the spectral parameter. The extra parameter $\eta$ is not actually essential because it can be eliminated by a rescaling of $x$ (unless one tends $\eta$ to 0 as in the limit to the Gaudin model). The $R$-matrix is an operator in the space $\mathbb{C}^{N|M} \otimes \mathbb{C}^{N|M}$. It can be represented as $R(x) = 1 \otimes 1 + \frac{2}{x}P$, where $P$ is the graded permutation operator given by $P = \sum_{a,b=1}^K (-1)^{p(b)}e_{ab} \otimes e_{ba}$. It acts on homogeneous vectors as follows: $P x \otimes y = (-1)^{p(x)p(y)}y \otimes x$.

Having in mind the construction of the spin chain on $L$ sites, one can realize the $R$-matrix as an operator in the space $\mathbb{C}^{N|M} \otimes (\mathbb{C}^{N|M})^{\otimes L}$:

$$R^{ij}(x) = 1 \otimes 1^{\otimes L} + \frac{\eta}{x} \sum_{a,b=1}^K (-1)^{p(b)}e_{ab} \otimes e_{ba}^{(j)}, \quad (2.2)$$

where $e_{ba}^{(j)} := 1^{\otimes(j-1)} \otimes e_{ba} \otimes 1^{\otimes(L-j)}$ for $j \in \{1, 2, \ldots, L\}$.\footnote{The definition of the graded tensor product implies that $e_{ab}^{(i)}e_{cd}^{(j)} = (-1)^{p(a) + p(b) + p(c) + p(d)}e_{cd}^{(j)}e_{ab}^{(i)}$ for $i \neq j$.} The first space $\mathbb{C}^{N|M}$ labelled by the index 0 is called the auxiliary space while the space $\mathcal{V} = (\mathbb{C}^{N|M})^{\otimes L}$ is the quantum space of the model. The matrix elements $(R^{ij}(x))_{ab}$ of the operator $R^{ij}(x)$ with respect to the auxiliary space are operators in the quantum space. They are defined by

$$R^{ij}(x)(v_a \otimes 1^{\otimes L}) = \sum_{b=1}^K (v_b \otimes 1^{\otimes L})(1 \otimes (R^{ij}(x))_{ba}) = \sum_{b=1}^K v_b \otimes (R^{ij}(x))_{ba},$$

$$R^{ij}(x)(1^{\otimes L} \otimes v_b) = \sum_{a=1}^K (1^{\otimes L} \otimes v_b)(R^{ij}(x))_{ab} = \sum_{a=1}^K (R^{ij}(x))_{ab} 1^{\otimes L} \otimes v_a.$$
where \( v_a \) are orthonormal basis vectors in \( \mathbb{C}^{|M|} \). From (2.2) we obtain:

\[
(\mathbf{R}^{ij}(x))_{ab} = \delta_{ab} 1^{|L|} + (-1)^{p(a)p(b)} \frac{\eta}{x} e_{ba}^{(j)},
\]

where we have used

\[
(e_{ac} \otimes e_{ca}^{(j)})(v_b \otimes 1^{|L|}) = (-1)^{p(e_{ac}^{(j)})p(v_b)} e_{ac} v_b \otimes e_{ca}^{(j)} = (-1)^{(p(c)+p(a))p(b)} \delta_{cb} v_a \otimes e_{ca}^{(j)}.
\]

For example, in the \( gl(1|1) \)-case the block matrix representation reads

\[
\mathbf{R}^{ij}(x) = 
\begin{pmatrix}
1 + \frac{2}{x} e_{11}^{(j)} & \frac{2}{x} e_{21}^{(j)} \\
\frac{2}{x} e_{12}^{(j)} & 1 - \frac{\eta}{x} e_{22}^{(j)}
\end{pmatrix}.
\]

Here \( I \equiv 1^{|L|} \). Below we will keep the notation \( I \) for identity elements of \( \text{End}(\mathbb{C}^{|M|}) \) and \( \text{End}(\mathbb{C}^{|L|}) \) and will often write \( I \) for the identity operator in any other spaces involved.

One may also extend the definition of the graded permutation to any two tensor factors of the space \( \mathcal{V} \):

\[
\mathbf{P}_{ij} = \sum_{a,b=1}^{K} (-1)^{p(b)} e_{ab}^{(i)} \otimes e_{ba}^{(j)}.
\]

On tensor products of the basis vectors it acts as follows (here \( i < j \)):

\[
\mathbf{P}_{ij}(v_{a_1} \otimes \cdots \otimes v_{a_i} \otimes \cdots \otimes v_{a_j} \otimes \cdots \otimes v_{a_L})
\]

\[
= (-1)^{p(a_i)+(p(a_i)+p(a_j))} \sum_{k=1}^{j-1} p(a_k) (v_{a_1} \otimes \cdots \otimes v_{a_j} \otimes \cdots \otimes v_{a_i} \otimes \cdots \otimes v_{a_L}).
\]

The aforesaid is related to the \( R \)-matrix in the evaluation representation of \( Y(gl(N|M)) \) based on the vector representation of \( gl(N|M) \). More generally, one can consider other irreducible finite-dimensional representations. In this paper we shall restrict our consideration to the class of covariant tensor representations \([24, 25, 26]\). Any partition \( \lambda \) (identified with the Young diagram) labels a covariant representation \( \pi_\lambda \) of the universal enveloping algebra \( U(gl(N|M)) \) if \( \lambda_{N+1} \leq M \). For any such representation one can construct an \( R \)-matrix acting in the tensor product of two spaces, one of which being the representation space \( V_{\lambda} \) where the representation \( \pi_\lambda \) is realized, while the other one is still \( \mathbb{C}^{|M|} \). We distinguish two \( R \)-matrices of this type depending on the order of the spaces. One is the \( R \)-matrix with the auxiliary space \( V_{\lambda} \). It has the form

\[
\mathbf{R}_\lambda(x) = 1 \otimes 1 + \frac{\eta}{x} \sum_{a,b=1}^{K} (-1)^{p(b)} \pi_\lambda(e_{ab}) \otimes e_{ba}.
\]

The auxiliary space of the other one is \( \mathbb{C}^{|N|} \):

\[
\mathbf{R}^\lambda(x) = 1 \otimes 1 + \frac{\eta}{x} \sum_{a,b=1}^{K} (-1)^{p(b)} e_{ab} \otimes \pi_\lambda(e_{ba}).
\]

Clearly, \( \mathbf{R}_\square(x) = \mathbf{R}^\square(x) = \mathbf{R}(x) \).
It is convenient to denote

\[ P_{\lambda}^{0j} = \sum_{a,b=1}^{K} (-1)^{p(b)} \pi_\lambda(e_{ab}) \otimes e_{ba}^{(j)}, \quad P_{0j}^{\lambda} = \sum_{a,b=1}^{K} (-1)^{p(b)} e_{ab} \otimes \pi_\lambda(e_{ba}^{(j)}), \tag{2.9} \]

then the \( R \)-matrix acting non-trivially in the tensor product of the auxiliary space \( V_\lambda \) and the \( j \)th space \( \mathbb{C}^{N|M} \) is \( R_{\lambda}^{0j}(x) = I + \frac{\eta}{x} P_{\lambda}^{0j} \) while the \( R \)-matrix acting non-trivially in the tensor product of the auxiliary space \( \mathbb{C}^{N|M} \) and the \( j \)th space \( V_{\lambda}(j) \) is \( R_{0j}^{\lambda(j)}(x) = I + \frac{\eta}{x} P_{0j}^{\lambda(j)}. \) The \( R \)-matrix \( R_\lambda(x) \) obeys the graded Yang-Baxter equation

\[ R_{12}^{\square}(x_1-x_2)R_{13}^{\lambda}(x_1-x_3)R_{23}^{\lambda}(x_2-x_3) = R_{23}^{\lambda}(x_2-x_3)R_{13}^{\lambda}(x_1-x_3)R_{12}^{\square}(x_1-x_2) \tag{2.10} \]

and possesses the invariance property

\[ \pi_\square(g) \otimes \pi_\lambda(g) R_\lambda(x) = R_\lambda(x) \pi_\square(g) \otimes \pi_\lambda(g) \tag{2.11} \]

valid for any \( g \). The graded Yang-Baxter equation for the \( R \)-matrix \( R_\lambda(x) \) reads

\[ R_{12(\lambda,\mu)}^{\lambda}(x_1-x_2)R_{13}^{\lambda}(x_1-x_3)R_{23}^{\lambda}(x_2-x_3) = R_{23}^{\lambda}(x_2-x_3)R_{13}^{\lambda}(x_1-x_3)R_{12(\lambda,\mu)}^{\lambda}(x_1-x_2), \tag{2.12} \]

where \( R_{12(\lambda,\mu)}^{\lambda}(x) \in \text{End}(V_\lambda \otimes V_\mu) \) is a yet more general \( R \)-matrix. Its explicit form is complicated. The invariance property for the \( R_\lambda(x) \) is similar to (2.11) with the opposite order of the tensor factors.

### 2.2 Inhomogeneous susy-XXX chains

Here we construct, using the \( R \)-matrices from the previous subsection, the inhomogeneous integrable susy-XXX spin chains with twisted boundary conditions.

#### 2.2.1 T-operators, non-local Hamiltonians and integrals of motion

Let \( g \in GL(N|M) \) be a group element represented by a diagonal (super)matrix \( g = \text{diag}(g_1, g_2, \ldots, g_K) = \sum_{a=1}^{K} g_a e_{aa} \). We call it the twist matrix with the twist parameters \( g_i \). It is used for the construction of an integrable spin chain with twisted boundary conditions. The T-operator (the transfer matrix) of the inhomogeneous spin chain with twisted boundary conditions is defined by

\[ T(x) = \text{str}_0\left( R^{0L}(x-x_L) \ldots R^{02}(x-x_2) R^{01}(x-x_1) (g \otimes I) \right), \tag{2.13} \]

where \( x_1, x_2, \ldots, x_L \) are inhomogeneity parameters. We assume that they are in general position meaning that \( x_i \neq x_j \) and \( x_i \neq x_j \pm \eta \) for all \( i \neq j \). As is known, the Yang-Baxter equation implies that the T-operators with fixed inhomogeneous and twist parameters commute: \([ T(x), T(x') ] = 0 \) for any \( x, x' \).

The dynamical variables of the model (which we call “spins” in analogy with the rank 1 case) are vectors in the vector representation of \( gl(N|M) \) realized in the spaces \( \mathbb{C}^{N|M} \)
attached to each site. One can define a set of non-local commuting Hamiltonians \( H_j \) as residues of \( T(x) \) at \( x = x_j \):

\[
T(x) = I_{\text{str}} g + \sum_{j=1}^{L} \frac{\eta H_j}{x - x_j}. \tag{2.14}
\]

In general, the Hamiltonians \( H_j \) imply a long-range interaction involving all spins in the chain (cf. [27]). Their explicit form is

\[
H_j = \prod_{k=1}^{j-1} \left( I + \frac{\eta P_{kj}}{x_j - x_k} \right) \prod_{k=j+1}^{L} \left( I + \frac{\eta P_{jk}}{x_j - x_k} \right) \tag{2.15}
\]

where \( g^{(j)} := 1^\otimes(j-1) \otimes g \otimes 1^\otimes(L-j) \) and \( P_{ij} \) is the graded permutation operator (2.5). In the second line, the sum is taken over all subsets \( I \) of the set \( \{1, 2, \ldots, L\} \setminus \{j\} \) including the empty one; \( |I| \equiv \text{Card} I \).

In addition to the Hamiltonians \( H_j \), there are other integrals of motion. It is easy to see that the operators

\[
M_a = \sum_{j=1}^{L} e^{(j)}_{aa}, \tag{2.17}
\]

referred to as weight operators, commute with the \( H_j \)'s: \([H_j, M_a] = 0\). Therefore, the eigenstates of the Hamiltonians can be classified according to the eigenvalues \((M_1, \ldots, M_K)\) of the weight operators referred to as weights. For example, in the \( gl(2) \)-case, \( M_1 \) and \( M_2 \) are the numbers of spins with positive and negative \( z \)-projections respectively.

Let \( \mathcal{V} = (C^N)^{\otimes M} = \bigoplus_{M_1, \ldots, M_K} \mathcal{V}(\{M_a\}) \) be the "weight decomposition" of the quantum space into the direct sum of weight spaces which are eigenspaces of the weight operators with the eigenvalues \( M_a \in \mathbb{Z}_{\geq 0}, \ a = 1, \ldots, K \). Then any eigenstate of the \( H_j \)'s belongs to some weight space \( \mathcal{V}(\{M_a\}) \). The dimension of the weight space \( \mathcal{V}(\{M_a\}) \) is given by

\[
\dim \mathcal{V}(\{M_a\}) = \frac{L!}{M_1! \ldots M_K!}.
\]

In particular, let \( 1 \leq a_0 \leq K \) be some fixed index, then the space with \( M_a = L\delta_{a_0} \) is one-dimensional. It is spanned by the vector \( v_{a_0} \otimes \ldots \otimes v_{a_0} \) which is an eigenvector of the Hamiltonians (2.15). Indeed, using (2.6) in the particular case \( a_1 = \ldots = a_L = a_0 \), one can see that

\[
H_j(v_{a_0} \otimes \ldots \otimes v_{a_0}) = g_{a_0} \prod_{k=1, k \neq j}^{L} \left( 1 + \frac{(-1)^{p(a_0)}}{x_j - x_k} \right) (v_{a_0} \otimes \ldots \otimes v_{a_0}). \tag{2.18}
\]
The weight operators are not all independent. Since \( \sum_a e_{aa} = 1 \), we have \( \sum_a M_a = L I \) and hence \( \sum_a M_a = L \). Note also that

\[
\sum_a M_a = L I
\]

so the model has \( L+N+M-1 \) independent commuting integrals of motion.

For completeness, we give here the definition of the T-operator for a more general inhomogeneous spin chain model with the quantum space \( \bigotimes_{j=1}^L V_{\Lambda(j)} \) and the auxiliary space \( \mathbb{C}^{N|M} \). The spin chain is defined by the following data:

- The number of sites, \( L \), and the inhomogeneity parameters \( x_i \) at each site;
- Covariant tensor representations of \( gl(N|M) \) indexed by the Young diagrams \( \Lambda(j) = (\Lambda_1^{(j)}, \ldots, \Lambda_K^{(j)}) \in (\mathbb{Z}_{\geq 0})^K \), \( \Lambda_1^{(j)} \geq \Lambda_2^{(j)} \geq \ldots \geq \Lambda_K^{(j)} \geq 0 \) (2.20)
  assigned to each site \( j = 1, \ldots, L \);
- Elements of the diagonal twist matrix \( g = \text{diag}(g_1, \ldots, g_K) \) (the twist parameters).

The T-operator

\[
T^\Lambda(x) = \text{str}_0 \left( R_{0L}^{\Lambda(L)}(x-x_L) \ldots R_{02}^{\Lambda(2)}(x-x_2) R_{01}^{\Lambda(1)}(x-x_1) (g \otimes I) \right) \tag{2.21}
\]

acts in the space \( \bigotimes_{j=1}^L V_{\Lambda(j)} \). One may also introduce a set of Hamiltonians \( H_j^\Lambda \) in the way similar to (2.14):

\[
T^\Lambda(x) = I \text{str} g + \sum_{j=1}^L \frac{\eta H_j^\Lambda}{x-x_j}. \tag{2.22}
\]

Our main objects of interest will be the T-operator \( T(x) \) and the Hamiltonians \( H_j \) of the model with vector representations at the sites corresponding to the choice \( \Lambda(j) = (1, 0, \ldots, 0) \) for all \( j = 1, \ldots, L \).

### 2.2.2 Diagonalization of the T-operator via Bethe ansatz

The algebraic form of the nested Bethe ansatz technique for the twisted \( Y(gl(n)) \) inhomogeneous spin chain [28] can be naturally extended to the \( Y(gl(N|M)) \)-case [2, 15, 29]. The T-operators and the Hamiltonians \( H_j^\Lambda \) can be diagonalized by this method. Although in what follows we need only the result for the choice \( \Lambda(j) = (1, 0, \ldots, 0) \) [3], we give here the general result for future references.

\[3\] The Bethe ansatz for trigonometric models closely related to this case was discussed in [30].
Later we will specify these general formulae for the highest weight conditions are Bethe roots. They satisfy the system of Bethe equations which are equivalent to the Bethe equations have the form:

\[ \prod_{\gamma=1}^{L_b} \frac{x - \mu^b_{\gamma} + (-1)^{p(b)} \eta}{x - \mu^b_{\gamma}} = \prod_{\gamma=1}^{L_b} \frac{x - \mu^{b-1}_{\gamma} + (-1)^{p(b)} \eta}{x - \mu^{b-1}_{\gamma}}, \]

The corresponding eigenvalues of the Hamiltonians (2.14) are as follows:

\[ H_{\Lambda, i} = \eta^{-1} \text{Res}_{x=x_i} T^\Lambda(z) = \sum_{b=1}^{K} \Lambda_b^{(k)} g_b \]

\[ \times \prod_{k=1}^{L} \frac{x-x_k + (-1)^{p(b)} \eta \Lambda_b^{(k)}}{x-x_k} \prod_{\gamma=1}^{L_b} \frac{x - \mu_{\gamma}^b + (-1)^{p(b)} \eta}{x - \mu_{\gamma}^b}. \]

It is convenient to set \( L_0 = L_K = 0 \). The parameters \( \mu^b_\alpha \) with

\[ \alpha = 1, ..., L_b, \quad b = 1, ..., K - 1, \quad L \geq L_1 \geq L_2 \geq ... \geq L_{K-1} \geq 0 \]

are Bethe roots. They satisfy the system of Bethe equations which are equivalent to the conditions

\[ \text{Res}_{x=\mu^b_\alpha} T^\Lambda(x) = 0 \quad \text{for all} \quad \alpha = 1, ..., L_b, \quad b = 1, \ldots, K - 1. \]

The Bethe equations have the form:

\[ g_b \prod_{k=1}^{L} \frac{\mu^b_\beta - x_k + (-1)^{p(b)} \eta \Lambda_b^{(k)}}{\mu^b_\beta - x_k} \prod_{\gamma=1}^{L_b} \frac{\mu^b_{\gamma} - \mu^{b-1}_{\gamma} + (-1)^{p(b)} \eta}{\mu^b_{\gamma} - \mu^{b-1}_{\gamma}} \]

\[ = g_{b+1} \prod_{\gamma \neq \beta}^{L_b} \frac{\mu^b_{\gamma} - \mu^b_{\gamma} + (-1)^{p(b+1)} \eta \Lambda_b^{(b+1)}}{\mu^b_{\gamma} - \mu^b_{\gamma} - (-1)^{p(b+1)} \eta} \prod_{\gamma=1}^{L_b+1} \frac{\mu^b_{\gamma} - \mu^{b+1}_{\gamma} - (-1)^{p(b+1)} \eta}{\mu^b_{\gamma} - \mu^{b+1}_{\gamma}}. \]

Later we will specify these general formulae for the highest weights

\[ \Lambda^{(j)} = (1, 0, ..., 0) \quad \text{for all} \quad j = 1, \ldots, L, \quad \text{i.e.,} \quad \Lambda_0^{(j)} = \delta_{01}. \]

With this choice the first product in the l.h.s. of (5.2) disappears for \( b \geq 2 \).

### 2.3 The higher T-operators

The \( R \)-matrix (2.7) allows one to construct a family of T-operators with the more general auxiliary space:

\[ T^\Lambda(x) = \text{str}_{V_\Lambda} \left( R^{0L}_\Lambda (x - x_L) \ldots R^{02}_\Lambda (x - x_2) R^{01}_\Lambda (x - x_1) (\pi_\Lambda(g) \otimes I) \right). \]
operators with fixed inhomogeneous and twist parameters commute with themselves:

\[ [T_\lambda(x), T_\mu(x')] = 0 \]  

(2.30)

for any \( x, x', \lambda, \mu \). At \( \lambda = 0 \) we put \( T_0(x) \) equal to the identity operator: \( T_0(x) = I \).

It is clear from (2.7) and (2.29) that at \( L = 0 \) (the empty quantum space) as well as in the limit \( x \to \infty \) for any \( L \) the T-operators become equal to the supercharacters \( \chi_\lambda(g) = \text{str}_V \chi_\lambda \). In what follows we also need the next-to-leading term of the expansion of \( T_\lambda(x) \) as \( x \to \infty \). From the definition (2.29) one obtains the expansion

\[ T_\lambda(x) = \chi_\lambda(g) I + \frac{\eta}{x} \sum_{a,b} \sum_{j=1}^L (-1)^{p(b)} \frac{\partial \chi_\lambda(e^{xg_{ab}})}{\partial \varepsilon} \bigg|_{\varepsilon=0} e_{ba}^{(j)} + O(1/x^2). \]  

(2.31)

Indeed, we have \( T_\lambda(x) = \chi_\lambda(g) I + \frac{\eta}{x} \sum_{j=1}^L \text{str}_{V_\lambda} \left( P_\lambda^{0j} \pi_\lambda(g) \right) + O(1/x^2) \) which is converted to the form (2.31) by the following chain of equalities:

\[ \text{str}_{V_\lambda} \left( P_\lambda^{0j} \pi_\lambda(g) \right) = \sum_{a,b} (-1)^{p(b)} \text{str}_{V_\lambda} \pi_\lambda(e_{ab} g) e_{ba}^{(j)} = \sum_{a,b} (-1)^{p(b)} \frac{\partial}{\partial \varepsilon} \left[ \text{str}_{V_\lambda} \pi_\lambda(e^{xg_{ab}}) \right] \bigg|_{\varepsilon=0} e_{ba}^{(j)}. \]

In fact the following explicit expression for the T-operator in terms of the supercharacters is available:

\[ T_\lambda(x) = \sum_{l=0}^L \frac{\eta^l}{l!} \sum_{i_1 < \ldots < i_l} \sum_{b_1, \ldots, b_l} \left( \frac{(-1)^{p(b_{\alpha})} e^{(i_\alpha)}}{x - x_{i_\alpha}} \frac{\partial}{\partial \varepsilon_{\alpha}} \right) \chi_\lambda(e^{x_1 e_{a_1 b_1}} \ldots e^{x_l e_{a_l b_l}}) \bigg|_{\varepsilon_{\alpha}=0} \]

\[ = \prod_{l=1}^L \left( I + \frac{\eta}{\sum_{a,b} (-1)^{p(b)} e^{(l)}} \frac{\partial}{\partial \varepsilon_{l}} \right) \chi_\lambda(e^{x_1 e_{a_1 b_1}} \ldots e^{x_l e_{a_l b_l}}) \bigg|_{\varepsilon_{l}=0}. \]  

(2.32)

Here we assume that \( p(\frac{\partial}{\partial \varepsilon_{\alpha}}) = p(\varepsilon_{\alpha}) = p(e_{b_\alpha a_\alpha}) \) and \( \varepsilon_{\alpha} \varepsilon_{\beta} = (-1)^{p(\varepsilon_{\alpha})} p(\varepsilon_{\beta}) \varepsilon_{\alpha}, \varepsilon_{\alpha} e_{b_\alpha a_\beta} = (-1)^{p(\varepsilon_{\alpha})} p(e_{b_\alpha a_\beta}) e_{b_\alpha a_\beta} \varepsilon_{\alpha} \). The summation over each \( a_\alpha \) and \( b_\alpha \) runs from 1 to \( K = N + M \).

The derivation of (2.32) is sketched in Appendix A.

As is known [32], supercharacters of the covariant tensor representations are expressed by the same formulas as for ordinary groups except for traces replaced by supertraces. In particular, the supercharacters are known to satisfy the Jacobi-Trudi identities [32] which have superficially the same form as the ones for the usual characters:

\[ \chi_\lambda(g) = \det_{1 \leq i,j \leq l_1} \chi_{\lambda_i-\lambda_j}(g) = \det_{1 \leq i,j \leq l_1} \chi_{\lambda_i-\lambda_j}(g). \]  

(2.33)

4 In parentheses in the second line one can recognize the (graded) co-derivative operator [31] which is a version of the matrix derivative. It proved to be a valuable technical tool for the proof of the CBR identities and the master T-operator construction. However, in this paper we do not use the co-derivative explicitly.
Here $\chi_k := \chi^{(k)}$ (respectively, $\chi^k := \chi^{(1^k)}$) is the character corresponding to the one-row (respectively, one-column) diagram of length $k$.

There exist analogues of these identities for the T-operators depending on the spectral parameter. These are the Cherednik-Bazhanov-Reshetikhin (CBR) determinant formulas sometimes called the quantum Jacobi-Trudi identities:

$$T_\lambda(x) = \det_{1 \leq i,j \leq \lambda'_1} T_{\lambda_i-i+j}(x-(j-1)\eta) = \det_{1 \leq i,j \leq \lambda_1} T_{N-i+j}^N(x+(j-1)\eta).$$

The determinants are well-defined because all the T-operators commute. Similarly to \(k\), \(T_k(x) := T^{(k)}(x)\) and \(T^k(x) := T_{(1^k)}(x)\) are the T-operators corresponding to the one-row and one-column diagrams respectively. There are the following “boundary conditions” for them: 

- \(T_k(x) = T^k(x) = 0\) if \(k < 0\) for \(N, M \neq 0\);
- \(T_k(x) = 0\) if \(k < 0\) or \(k > M\) at \(N = 0\);
- \(T^k(x) = 0\) if \(k < 0\), or \(k > N\) at \(M = 0\).

For models based on \(Y(gl(N))\)-invariant R-matrices, the quantum Jacobi-Trudi identities follow from resolutions of modules for the Yangian \(Y(gl(N))\) \[33\]. In the physical literature, they appeared in \[34\] for \(gl(N)\) (see also \[35\]), in \[36\] for \(gl(N|M)\) and in \[37, 38\] for some infinite dimensional representations in the context of AdS/CFT correspondence.

Remarkably, their general form does not depend on the grading, although their matrix elements and eigenvalues of the T-operators do. In fact the assertion that the T-operators for supersymmetric integrable models satisfy the quantum Jacobi-Trudi identities was a conjecture in \[36\]. A direct proof of this fact was given in \[31\] for models based on the \(Y(gl(N|M))\)-invariant R-matrices, where each “spin” of the chain was assumed to be in the vector representation. A proof which is independent of the quantum space is only available \[39\] for models based on the \(q\)-deformed algebra \(U_q(sl(2|1))\) in the case of rectangular Young diagrams.

The eigenvalues of the T-operators \[2.29\] are rational functions of \(x\) with \(L\) poles. Another normalization, where they are polynomials in \(x\) of degree \(L\), is also convenient and even preferable for the link to classical integrable hierarchies. The polynomial form of the T-operators is obtained as follows:

$$T_\lambda(x) = \prod_{j=1}^L (x-x_j) T_\lambda(x).$$

In particular for \(\lambda = \emptyset\), we have \(T_\emptyset(x) = \prod_{j=1}^L (x-x_j)\). The CBR-formulas \[2.34\] in the polynomial normalization acquire the form

- \(T_\lambda(x) = \left( \prod_{k=1}^{\lambda'_1} T_{\lambda_1-k}^N(x-k\eta) \right)^{-1} \det_{1 \leq i,j \leq \lambda'_1} T_{\lambda_i-i+j}(x-(j-1)\eta), \)

- \(T_\lambda(x) = \left( \prod_{k=1}^{\lambda_1} T_{\lambda_1-k}^N(x-k\eta) \right)^{-1} \det_{1 \leq i,j \leq \lambda_1} T_{N-i+j}^N(x+(j-1)\eta). \)

\[5\] There was a minor gap in the proof given in \[31\] which was filled in the appendix of \[4\] for the \(gl(N)\) case. The proof for \(gl(N|M)\) is similar.
2.4 The construction of the master T-operator

The master T-operator is a generating function of the T-operators \( T_\lambda(x) \) of a special form. It can be introduced in the same way as in [4]. (In an implicit form, the notion of the master T-operator appeared in [5].) For this we should recall the definition of the Schur functions.

Let \( t = \{t_1, t_2, t_3, \ldots \} \) be an infinite set of complex parameters (we call them times) and \( s_\lambda(t) \) be the standard Schur functions \((S\text{-}functions)\) which can be introduced as

\[
s_\lambda(t) = \det_{1 \leq i, j \leq \lambda_1} h_{\lambda_i - i + j}(t),
\]

where the polynomials \( h_k(t) = s_{(k)}(t) \) (the elementary Schur functions) are defined by

\[
e^\xi(t, z) = \sum_{k=0}^{\infty} h_k(t) z^k, \quad \xi(t, z) := \sum_{n=1}^{\infty} t_n z^n.
\] (2.38)

It is convenient to put \( h_k(t) = 0 \) for negative \( k \) and \( s_{\emptyset}(t) = 1 \). As is obvious from the definition, the Schur functions are polynomials in the times \( t_i \). The Schur functions are often regarded as symmetric functions of variables \( \xi_\alpha \) such that

\[
t_k = \frac{1}{k} \sum_\alpha \xi_\alpha^k.
\]

The supercharacters can be expressed in terms of the Schur functions\(^6\) as follows [24]. Set \( y_k = \frac{1}{k} \text{str} g^k \), where \( \text{str} g^k \) is the supertrace of \( g^k \) realized in the vector representation as a \( K \times K \) diagonal matrix: \( \text{str} g^k = \sum_{a=1}^{N} g_a^k - \sum_{b=N+1}^{N+M} g_b^k \). Then \( \chi_\lambda(g) = s_\lambda(y) \). This is equivalent to the fact that \( (\text{sdet}(1 - zg))^{-1} \) is the generating function for the supercharacters corresponding to one-row diagrams: \( (\text{sdet}(1 - zg))^{-1} = \sum_{k \geq 0} h_k(y) z^k \). For later use we need the following identity for the supercharacters:

\[
\sum_\lambda \chi_\lambda(g)s_\lambda(t) = \exp\left(\sum_{k \geq 1} t_k \text{str} g^k\right),
\] (2.39)

which is simply the Cauchy-Littlewood identity for the Schur functions [32]. Here and below, the sum \( \sum_\lambda \) goes over all Young diagrams \( \lambda \) including the empty one.

Now we are ready to introduce the master T-operator as an infinite sum over the Young diagrams:

\[
T(x, t) = \sum_\lambda T_\lambda(x)s_\lambda(t). \tag{2.40}
\]

It immediately follows from the definition that the T-operators \( T_\lambda(x) \) can be restored from it by applying the differential operators in the times \( t_i \):

\[
T_\lambda(x) = s_\lambda(\delta t)T(x, t)\Big|_{t=0}, \tag{2.41}
\]

---

6 This expression is equivalent to the one in terms of the so-called supersymmetric Schur functions \((SS\text{-}functions)\) [40] which are symmetric functions of two sets of variables, \( \{g_1, \ldots, g_N\} \) and \( \{g_{N+1}, \ldots, g_{N+M}\} \).
where $\tilde{\partial} := \{ \partial_{t_1}, \frac{1}{2} \partial_{t_2}, \frac{1}{3} \partial_{t_3}, \ldots \}$. In particular, $T_0(x) = T(x, 0) = \prod_{j=1}^L (x - x_j) I$ and $T_\square(x) = \partial_{t_1} T(x, t) \big|_{t=0}$, so that the T-operator $T(x) = T_1(x) = T_\square(x)$ \eqref{2.13} is expressed as the logarithmic derivative of the master T-operator:

$$T(x) = \partial_{t_1} \log T(x, t) \big|_{t=0}. \quad \text{(2.42)}$$

Using \eqref{2.31} and the Cauchy-Littlewood identity \eqref{2.39}, one can derive the following expansion of the master T-operator as $x \to \infty$:

$$\frac{T(x, t)}{T_0(x)} = e^{\text{str}\xi(t, g)} \left( I + \frac{\eta}{x} \sum_{j=1}^L \sum_{k \geq 1} kt_k (g^{(j)})^k + O(1/x^2) \right). \quad \text{(2.43)}$$

Note that the sign factor $(-1)^{\rho(b)}$ coming from the definition of the $P_{\lambda}^{0j}$ \eqref{2.39} cancels against the one coming from the supertrace, so the two leading terms do not actually depend on the grading (except for the supertrace in the common factor). More generally, using \eqref{2.32} and the Cauchy-Littlewood identity one arrives, in a similar way, to the following explicit expression for the master T-operator:

$$\frac{T(x, t)}{T_0(x)} = \sum_{l=0}^L \eta' \sum_{i_1 < \ldots < i_l} \sum_{a_1, \ldots, a_l} \left( \prod_{\alpha=1}^{l} \frac{(-1)^{\rho(b_{a_\alpha}^l)}}{x - x_{i_\alpha}} \frac{\partial}{\partial \varepsilon_{\alpha}} \right) e^{\text{str}\xi(t, e^{i\varepsilon_{a_1} b_1} \ldots e^{i\varepsilon_{a_l} b_l} g)} \bigg|_{\varepsilon_{\alpha}=0}$$

$$= \prod_{l=1}^L \left( I + \eta \sum_{a_1, b_l} \frac{(-1)^{\rho(b_1)}}{x - x_l} \frac{\partial}{\partial \varepsilon_l} \right) e^{\text{str}\xi(t, e^{i\varepsilon_{a_1} b_1} \ldots e^{i\varepsilon_{a_l} b_l} g)} \bigg|_{\varepsilon_l=0} \quad \text{(2.44)}$$

Given $z \in \mathbb{C}$, we will use the standard notation $t \pm [z^{-1}]$ for the following special shift of the time variables:

$$t \pm [z^{-1}] := \{ t_1 \pm z^{-1}, t_2 \pm \frac{1}{2}z^{-2}, t_3 \pm \frac{1}{3}z^{-3}, \ldots \}. $$

As we shall see below, $T(x, t \pm [z^{-1}])$ regarded as functions of $z$ with fixed $x, t$ play an important role. Here we only note that equation \eqref{2.41} implies that $T(x, 0 \pm [z^{-1}])$ are the generating series for the T-operators corresponding to the one-row and one-column diagrams respectively:

$$T(x, [z^{-1}]) = \sum_{s=0}^{\infty} z^{-s} T_s(x), \quad T(x, -[z^{-1}]) = \sum_{a=0}^{\infty} (-z)^{-a} T^a(x). \quad \text{(2.45)}$$

### 2.5 The master T-operator and the mKP hierarchy

#### 2.5.1 The bilinear identity for the master T-operator

The main property of the master T-operator which provides a remarkable link to the theory of classical non-linear integrable equations and their hierarchies is given by the following statement.
Theorem 2.1 The master T-operator (2.40) satisfies the bilinear identity for the mKP hierarchy:
\[
\oint \frac{z^{(x-x')/\eta}e^{\xi(t-t',z)}}{C} T(x, t - [z^{-1}]) T(x', t' + [z^{-1}]) dz = 0
\] (2.46)
for all \( t, t', x \) and \( x' \). The integration contour \( C \) encircles the cut \([0, \infty)\) between 0 and \( \infty \) and does not enclose any singularities coming from the \( T \)-factors.

The bilinear identity has superficially the same form as the one for the master T-operator for the ordinary (non-supersymmetric) spin chains associated with \( Y(gl(N)) \) and can be proved in a similar way. The proof is based on the CBR formulas (2.36) or (2.37). The definition of the master T-operator (2.40) can be interpreted as the expansion of the tau-function in Schur polynomials [10, 41, 42]. The functional relations for quantum transfer matrices [33, 34, 35, 36] are then the Plücker-like relations for coefficients of the expansion [7].

The bilinear identity (2.46) is a source of various bilinear Hirota equations for the master T-operator. For example, setting \( x' = x - \eta, t' = t - [z_1^{-1}] - [z_2^{-1}] \), we obtain the 3-term difference Hirota equation
\[
z_2 T(x + \eta, t - [z_1^{-1}]) T(x, t - [z_1^{-1}]) - z_1 T(x + \eta, t - [z_1^{-1}]) T(x, t - [z_2^{-1}]) + (z_1 - z_2) T(x + \eta, t) T(x, t - [z_1^{-1}] - [z_2^{-1}]) = 0
\] (2.47)
which is in fact equivalent to the bilinear identity (see [16]).

2.5.2 The Baker-Akhiezer functions

Let \( T(x, t) \) be any eigenvalue of the master T-operator. As it follows from (2.46), it is a tau-function of the mKP hierarchy. It is then natural to incorporate other key ingredients of the soliton theory. The most important for us are the Baker-Akhiezer (BA) function and its adjoint. In what follows we refer to both as the BA functions. They are defined as
\[
\psi(x, t; z) = z^{x/\eta} e^{\xi(t,z)} \frac{T(x, t - [z^{-1}])}{T(x, t)}, \quad (2.48)
\]
\[
\psi^*(x, t; z) = z^{-x/\eta} e^{-\xi(t,z)} \frac{T(x, t + [z^{-1}])}{T(x, t)}. \quad (2.49)
\]
We are going to also consider the operator-valued BA functions \( \hat{\psi}(x, t; z) \) defined by the same formulas with \( T(x, t) \) substituted by \( T(x, t) \). Since these operators commute for all \( x, t \), the operator \( \hat{\psi}(x, t; z) \) is well-defined.

\footnote{It is pertinent to note possible generalizations of this picture. There are functional relations [43, 47] and their Wronskian-like determinant solutions [44, 45] related to infinite-dimensional representations of \( gl(N|M) \). The solutions are given by changing the expansion point of the generating function for the T-operators. Therefore, there is a possibility that the master T-operator (2.40) is still relevant for such systems after a sort of analytic continuation. In this paper, we consider only covariant tensor representations of \( gl(N|M) \). There are also contravariant and mixed representations whose characters are labelled by a pair of Young diagrams. It is an interesting open problem whether the corresponding master T-operator is a tau-function of any hierarchy of soliton equations (like the 2D Toda lattice).}
According to the definition of the master $T$-operator, $T(x, \mathbf{t} \mp [z^{-1}])$ is an infinite series in $z^{-1}$. From (2.44), one can see that this series converges to a rational function of $z$ for any $x, \mathbf{t}$ if $|z| > \max \{|g_1|, |g_2|, \ldots, |g_K|\}$. Explicitly, we obtain:

$$
T(x, \mathbf{t} \mp [z^{-1}]) = \prod_{\eta=1}^{L} \left((x - x_i)I + \eta \sum_{a_i,b_i} (-1)^{\rho(b_i)} e_{b_i a_i}^{(l)} \frac{\partial}{\partial \varepsilon_i}\right)
$$

$$
\times \left\{\text{sdet} \left(1 - z^{-1}g_{a_L b_L, \ldots, a_1 b_1}\right)\right\} \left|_{\varepsilon_i=0}^{\pm 1} e^{\text{str} \xi(t, z)}\right\}^{\pm1},
$$

where we have put $g_{a_L b_L, \ldots, a_1 b_1} \equiv e^{\varepsilon_a e_{ab} b_n} \ldots e^{\varepsilon_1 e_{a_1 b_1} g}$ for brevity. Therefore, the function $z^{-x/\eta} e^{-\xi(t, z)} \psi(x, \mathbf{t} \pm z)$ (resp. $z^{x/\eta} e^{\xi(t, z)} \psi^*(x, \mathbf{t} \pm z)$) is a rational function of $z$ with poles at the points $z = g_a$ (the eigenvalues of the matrix $\mathbf{g}$) for $a \in \mathfrak{F}$ (resp., $a \in \mathfrak{B}$) of at least first order. It can be also derived from (2.50)

$$
\lim_{z \to 0} z^{\pm(N-M)} T(x, \mathbf{t} \mp [z^{-1}]) = (-1)^{N-M} (\text{sdet} \mathbf{g})^{\pm1} T(x \pm \eta, \mathbf{t}).
$$

The left hand side is to be understood as the analytic continuation to the point $z = 0$ of the analytic function (rational in our case) defined by the series which converges in a neighbourhood of infinity.

Since any eigenvalue $T(x, \mathbf{t})$ is a polynomial in $x$, the functions $z^{-x/\eta} \psi$ and $z^{x/\eta} \psi^*$, regarded as functions of $x$, are rational functions with $L$ zeros and $L$ poles which are simple in general position. From (2.40), (2.35) and (2.29), using the Cauchy-Littlewood identity, or directly from (2.50), we conclude that

$$
\lim_{z \to \infty} \frac{T(x, \mathbf{t} \mp [z^{-1}])}{T(x, \mathbf{t})} = e^{\text{str} \xi(t, \mp [z^{-1}], \mathbf{g})} = e^{\text{str} \xi(t, \mathbf{g})} = [\text{sdet} \left(1 - z^{-1} \mathbf{g}\right)]^{\pm1},
$$

hence

$$
\lim_{z \to \infty} z^{-x/\eta} e^{-\xi(t, z)} \psi(x, \mathbf{t}, z) = z^{-N+M} \text{sdet}(z \mathbf{1} - \mathbf{g}),
$$

$$
\lim_{z \to \infty} z^{x/\eta} e^{\xi(t, z)} \psi^*(x, \mathbf{t}, z) = z^{N-M} (\text{sdet}(z \mathbf{1} - \mathbf{g}))^{-1}.
$$

---

8 The main underlying statement is that

$$
\left(x I + \eta \sum_{a,b} (-1)^{\rho(b)} e_{b a}^{(l)} \frac{\partial}{\partial \varepsilon}\right) [\text{sdet} (e^{x} e_{ab} g)]^{\pm1} \Phi|_{\varepsilon=0} = [\text{sdet} g]^{\pm1} \left[(x \pm \eta) I + \eta \sum_{a,b} (-1)^{\rho(b)} e_{b a}^{(l)} \frac{\partial}{\partial \varepsilon}\right] \Phi|_{\varepsilon=0}
$$

for any $g \in GL(M|N)$ and any $\Phi \in \text{End}(V_{l+1} \otimes V_{l+2} \otimes \ldots \otimes V_l)$ (here $V_i \cong \mathbb{C}^{N|M}$). It immediately follows from the Leibniz rule and the identity

$$
\frac{\partial}{\partial \varepsilon} [\text{sdet} (e^{x} e_{ab} g)]^{\pm1} \biggr|_{\varepsilon=0} = \text{str}(e_{ab}) [\text{sdet} g]^{\pm1} = (-1)^{\rho(b)} \delta_{ab} [\text{sdet} g]^{\pm1}
$$

which is easy to check.
The (operator-valued) functions $\hat{\psi}(x, z) := \hat{\psi}(x, 0; z)$ and $\hat{\psi}^*(x, z) := \hat{\psi}^*(x, 0; z)$, as well as the corresponding eigenvalues, are called stationary BA functions. Their explicit form directly follows from (2.50):

$$z^{-x/\eta} \hat{\psi}(x, z) = \sum_{l=0}^{L} \eta^l \sum_{i_1 < \cdots < i_l} \sum_{a_1, \ldots, a_l} \left( \prod_{\alpha=1}^{l} \frac{(-1)^{p(b_{\alpha})} e^{(i_{\alpha})}_{b_{\alpha}a_{\alpha}}}{x - x_{i_{\alpha}}} \frac{\partial}{\partial \varepsilon_{\alpha}} \right) \left| \det \left( 1 - z^{-1} g_{a_1 \cdots a_l} b_1 \right) \right|_{\varepsilon_{\alpha}=0},$$

$$z^{x/\eta} \hat{\psi}^*(x, z) = \sum_{l=0}^{L} \eta^l \sum_{i_1 < \cdots < i_l} \sum_{b_1, \ldots, b_l} \left( \prod_{\alpha=1}^{l} \frac{(-1)^{p(b_{\alpha})} e^{(i_{\alpha})}_{b_{\alpha}a_{\alpha}}}{x - x_{i_{\alpha}}} \frac{\partial}{\partial \varepsilon_{\alpha}} \right) \left[ \det \left( 1 - z^{-1} g_{a_1 \cdots a_l} b_1 \right) \right]^{-1}$$

(2.54)

(2.55)

In particular, we have the expansion of $\hat{\psi}(x, z)$ as $|x| \to \infty$:

$$z^{-x/\eta} \hat{\psi}(x, z) = \text{sdet} \left( 1 - z^{-1} g \right) \left( 1 - \frac{\eta}{x} \sum_{j=1}^{K} \sum_{a=1}^{L} g_{a} e^{(j)}_{a} \psi(x, z) + O(1/x^2) \right)$$

(2.56)

(we need it in the next section).

For calculations in the next section we also need the following general properties of the BA functions of the mKP hierarchy.

a) They obey the differential-difference equations of the form

$$\partial_{t_{i}} \psi(x, t; z) = \psi(x + \eta, t; z) + V(x, t) \psi(x, t; z),$$

$$- \partial_{t_{i}} \psi^*(x, t; z) = \psi^*(x - \eta, t; z) + V(x - \eta, t) \psi^*(x, t; z)$$

(2.57)

(2.58)

(the linear problems), where $V(x, t) = \partial_{t_{i}} \log \frac{T(x + \eta, t)}{T(x, t)}$ (see, e.g., [11, 12]);

b) They obey the relation

$$\partial_{m} \log \frac{T(x + \eta, t)}{T(x, t)} = \text{res}_{\infty} \left( \psi(x, t; z) \psi^*(x + \eta, t; z) z^{m} dz \right),$$

(2.59)

where the residue is normalized as $\text{res}_{\infty} z^{-1} dz = 1$. It can be derived from (2.46) and (2.51) in the same way as in [8].

3 From the master T-operator to the classical RS model and back

3.1 Eigenvalues of the spin chain Hamiltonians as velocities of the RS particles

As we already mentioned in the previous section, the eigenvalues of the master T-operator are polynomials in the spectral parameter $x$ of degree $L$:

$$T(x, t) = e^{str_x(t, g)} \prod_{k=1}^{L} (x - x_k(t)).$$

(3.1)
The roots have their own dynamics in the times. The very fact that $T(x, t)$ is a tau-function of the mKP hierarchy implies [16, 17] that the roots $x_i$ move in the time $t_1$ as particles of the RS $L$-body system [18]. Moreover, their motion in the higher times $t_k$ is the same as motion of the RS particles caused by the higher Hamiltonian flows of the RS system (see [17, 18] which extend the methods developed by Krichever [47] and Shiota [48]). We have $T(x, 0) = T_\emptyset(x) = \prod_{k=1}^{L} (x - x_k)$, where $x_k = x_k(0)$. This means that

(i) The inhomogeneity parameters $x_k$ of the spin chain should be identified with initial positions $x_k(0)$ of the RS particles.

With the help of (2.42) we can write:

$$\frac{T_\tau(x)}{T_\emptyset(x)} = \partial_{t_1} \log T(x, t)|_{t=0} = \text{str} g - \sum_{k=1}^{L} \frac{\dot{x}_k(0)}{x - x_k},$$

(3.2)

where $\dot{x}_k(0) := \partial_{t_1} x_k(t)|_{t=0}$. Comparing this with (2.14), we find:

$$\dot{x}_k(0) = -\eta H_k,$$

(3.3)

where $H_k$ is an eigenvalue of $H_k$. Therefore, in addition to (i) we conclude that

(ii) The eigenvalues $H_k$ of the susy-XXX spin chain Hamiltonians are expressed through the initial velocities of the RS particles as $H_i = -\dot{x}_i(0)/\eta$.

In other words, any point in the phase space of the $L$-body RS system with coordinates $\{x_i, \dot{x}_i\}$ corresponds to an eigenstate, with the eigenvalues $H_i = -\dot{x}_i/\eta$, of the Hamiltonians of the susy-XXX spin chain on $L$ sites with the inhomogeneity parameters $x_i$.

This unexpected connection between quantum spin chains and the classical RS model was pointed out in [4] as a corollary of the Hirota bilinear equations for the master T-operator. A similar relation between quantum Hamiltonians in the Gaudin model and velocities of particles in the classical Calogero-Moser model was found in [49] using different methods (see also [50, 51] for further developments). The message of the present paper is that the identifications (i) and (ii) are in fact independent of the grading: their form is the same for all spin chains of the XXX type associated with any (super)algebra $gl(N|M)$ including the ordinary algebras $gl(N|0) = gl(N)$.

### 3.2 Lax pair for the RS model from dynamics of poles

To make the correspondence “quantum spin chains ↔ classical RS systems” (the QC correspondence) complete, we need the Lax matrix for the RS model. At this stage the set-up is exactly the same as in [8]. Here we repeat the main formulas with some comments skipping the details.

Below we will derive equations of motion for the $t_1$-dynamics of the $x_i$’s using Krichever’s method [47], the starting point of which is the linear problem (2.57) for the BA

---

9 In [6] it was obtained from the master T-operator construction for the Gaudin model.
function. Essentially, the derivation is not specific to the master $T$-operator case but only depends on the polynomial form of the tau-function.

One can derive equations of motion for the $x_i$’s performing the pole expansion of the linear problem (2.57). It is convenient to denote $t_1 = t$ and put all higher times equal to 0 because they are irrelevant for this derivation. Below in this section we often write simply $t$ instead of $t$. According to (2.48), the general form of $\psi$ as a function of $x$ is

$$\psi(x, t; z) = z^{x/\eta} e^{t z} \left( c_0(z) + \sum_{j=1}^L \frac{c_j(z, t)}{x - x_j(t)} \right), \quad (3.4)$$

where $c_0(z) = \text{sdet}(1 - z^{-1} g)$ (see (2.52)). One should substitute it into the linear equation (2.57) with

$$V(x, t) = \partial_t \log \frac{T(x + \eta, t)}{T(x, t)} = \sum_{k=1}^L \left( \frac{\dot{x}_k}{x - x_k} - \frac{\dot{x}_k}{x - x_k + \eta} \right), \quad x_k = x_k(t) \quad (3.5)$$

and cancel all the poles at $x = x_i$ and $x = x_i - \eta$ (possible poles of the second order cancel automatically). This yields an overdetermined system of linear equations for the coefficients $c_i$:

$$\begin{cases}
(z1 - Z) \vec{c} = c_0(z) \dot{X} \vec{1} \\
\dot{\vec{c}} = G \vec{c},
\end{cases} \quad (3.6)$$

where $\vec{c} = (c_1, c_2, \ldots, c_L)^t$, $\vec{1} = (1, 1, \ldots, 1)^t$ are $L$-component vectors and the $L \times L$ matrices $X = X(t)$, $Z = Z(t)$, $G = G(t)$ are defined by their matrix elements as follows:

$$X_{ij} = x_i \delta_{ij}, \quad Z_{ij} = \frac{\dot{x}_i}{x_i - x_j - \eta} \quad (3.7)$$

$$G_{ij} = \left( \sum_{k \neq i} \frac{\dot{x}_k}{x_i - x_k} - \sum_{k \neq i} \frac{\dot{x}_k}{x_i - x_k + \eta} \right) \delta_{ij} + \left( \frac{\dot{x}_i}{x_i - x_j} - \frac{\dot{x}_i}{x_i - x_j - \eta} \right) (1 - \delta_{ij}). \quad (3.8)$$

The explicit form of the matrix $G$ is not used in what follows. As is easy to check, the matrix $[X, Z] - Z$ has rank 1. More precisely, these matrices satisfy the commutation relation

$$[X, Z] = \eta Z + \dot{X} E, \quad (3.9)$$

where $E = \vec{1} \otimes \vec{1}$ is the $L \times L$ matrix with all entries equal to 1. As a consequence of this commutation relation, we mention the identity $\vec{1}^t Z^k \dot{X} \vec{1} = -\eta \text{tr} Z^{k+1}$ which holds for any $k \geq 0$ (see [8]).

The compatibility condition of the problems (3.6) is the Lax equation

$$\dot{Z} = [G, Z] \quad (3.10)$$

which is equivalent to the equations of motion

$$\ddot{x}_i = -\sum_{k \neq i} \frac{2\eta^2 \dot{x}_i \dot{x}_k}{(x_i - x_k)^2 - \eta^2}, \quad i = 1, \ldots, L. \quad (3.11)$$
This dynamical system called the RS model is sometimes referred to as the relativistic deformation of the Calogero-Moser model, the parameter $\eta$ being the inverse “velocity of light”. The Hamiltonian formulation is given in the appendix. The integrability of the RS model follows from the Lax representation. The matrix $Z$ is the Lax matrix. As it follows from (3.10), the time evolution preserves its spectrum, i.e., the coefficients $J_k$ of the characteristic polynomial

$$\det(zI - Z(t)) = \sum_{k=0}^{L} J_k z^{L-k}$$

are integrals of motion. Equivalently, one can say that eigenvalues of the Lax matrix are integrals of motion.

For completeness, we also present here the linear problem for coefficients of the adjoint BA function

$$\psi^*(x,t;z) = z^{-x/\eta} e^{-tz} \left( c_0^{-1}(z) + \sum_{j=1}^{L} \frac{c_j^*(z,t)}{x - x_j(t)} \right).$$

As a counterpart of (3.6), we get, using the equations of motion,

$$\begin{align*}
\vec{c}^t \dot{X}^{-1}(z1 - Z) &= -c_0^{-1}(z) \vec{1}^t \\
\partial_t(\vec{c}^t \dot{X}^{-1}) &= -\vec{c}^t \dot{X}^{-1} \mathcal{G}.
\end{align*}$$

Here $\vec{c}^t = (c_1^t, c_2^t, \ldots, c_L^t)$ and $\vec{1}^t = (1, 1, \ldots, 1)$ (note that $\vec{1}^t \mathcal{G} = 0$). Regarding these equations as overdetermined linear problems for the (co)vector $\vec{c}^t \dot{X}^{-1}$, one comes to the same Lax equation (3.10) as their compatibility condition. The adjoint linear problems (3.14), together with general relation (2.59), are used for the extension of the time dynamics of the $x_i$’s to the whole hierarchy, as it has been done in [17, 8], see Appendix B.

### 3.3 The BA function and the master T-operator

The solution for the vector $\vec{c}$ reads $\vec{c}(z,t) = c_0(z)(z1 - Z(t))^{-1} \dot{X} \vec{1}$. The BA function $\psi$ is then given by the formula

$$\psi = c_0(z) z^{-x/\eta} e^{tz} \left( 1 + \vec{1}^t(x1 - X)^{-1}(z1 - Z)^{-1} \dot{X} \vec{1} \right).$$

Similar formulas can be obtained for the adjoint vector $\vec{c}^*$ and the adjoint BA function:

$$\vec{c}^*(z,t) = -c_0^{-1}(z) \vec{1}^t (z1 - Z(t))^{-1} \dot{X},$$

$$\psi^* = c_0^{-1}(z) z^{-x/\eta} e^{-tz} \left( 1 - \vec{1}^t(z1 - Z)^{-1}(x1 - X)^{-1} \dot{X} \vec{1} \right).$$

It is easy to see that for non-zero values of the higher times the BA functions are given by the same formulas with the factor $e^{\pm tz}$ substituted by $e^{\pm \xi(t,z)}$. Writing $\vec{1}^t A \vec{1} = \text{tr}(AE)$
and using the commutation relation (3.9), one can represent these expressions as ratios of determinants:

\[
\psi(x,t; z) = \text{sdet} \left( 1 - z^{-1}g \right) z^{x/\eta} e^{\xi(t, z)} \frac{\det \left[ (x1 - X)(z1 - Z) - \eta Z \right]}{\det(x1 - X) \det(z1 - Z)},
\] (3.17)

\[
\psi^*(x,t; z) = \left[ \text{sdet} \left( 1 - z^{-1}g \right) \right]^{-1} z^{-x/\eta} e^{-\xi(t, z)} \frac{\det \left[ (z1 - Z)(x1 - X) + \eta Z \right]}{\det(x1 - X) \det(z1 - Z)}.
\] (3.18)

In particular, the stationary BA functions are given by

\[
\psi(x,z) = \text{sdet} \left( 1 - z^{-1}g \right) z^{x/\eta} \frac{\det \left[ (x1 - X0)(z1 - Z0) - \eta Z0 \right]}{\det(x1 - X0) \det(z1 - Z0)},
\] (3.19)

\[
\psi^*(x,z) = \left[ \text{sdet} \left( 1 - z^{-1}g \right) \right]^{-1} z^{-x/\eta} \frac{\det \left[ (z1 - Z0)(x1 - X0) + \eta Z0 \right]}{\det(x1 - X0) \det(z1 - Z0)}.
\] (3.20)

Hereafter, we use the notation \(X_0 = X(0), Z_0 = Z(0)\). Using (2.48), one can obtain from (3.17) an explicit determinant formula for eigenvalues of the master T-operator:

\[
T(x,t) = e^{\text{str} \xi(t,g)} \det \left( x1 - X0 + \sum_{k \geq 1} kt_k Z_0^k \right).
\] (3.21)

Formulas (3.17) and (3.21) are not new in the context of classical integrable hierarchies (see, e.g., [48, 52, 17]). The new observation is the close connection with quantum spin chains. It is important to stress that we can understand (3.19) and (3.21) in the operator sense, i.e. as expressions for the quantum operators \(\hat{\psi}(x,z), T(x,t)\) in terms of the matrices \((X_0)_{ij} = x_i \delta_{ij} I, (Z_0)_{ij} = \frac{\eta H_i}{x_j - x_i + \eta}\). The latter is the Lax matrix \(Z_0\) with the operator-valued entries given by equation (3.7) with the substitution (3.3).

To summarize, we have derived equations of motion of the RS model for roots of the master T-operator, together with the Lax representation. Then, embedding the initial quantum problem into the context of the classical RS model, we have obtained explicit operator expressions for the BA function and the master T-operator in terms of the quantum spin chain Hamiltonians. In the next section we show how one can reformulate the spectral problem for the quantum Hamiltonians in terms of an inverse spectral problem for the RS Lax matrix.

4 Spectrum of the spin chain Hamiltonians from the classical RS model

4.1 Twist parameters as eigenvalues of the Lax matrix

The expansion of the stationary operator-valued BA function \(\hat{\psi}\) at large \(|x|\) has the same form as in the \(gl(N)\) case [8] except for the overall super-determinant. In fact we have

\[10\] The order of the factors \(x1 - X\) and \(z1 - Z\) under the determinant upstairs is actually not important because of the identity \(\det(AB + A_1) = \det(BA + A_1)\) valid for any matrices \(A, B, A_1\) such that \([A, A_1] = 0\).
two different (but equivalent) expressions for $\hat{\psi}$: \ref{eq:2.54} and \ref{eq:3.19}. Let us compare their large $|x|$ expansions. The large $|x|$ expansion of \ref{eq:2.54} is given by \ref{eq:2.56}:

$$
\hat{\psi}(x, z) = c_0(z) z^{x/\eta} \left( I - \sum_{j=1}^{L} \sum_{a=1}^{K} \frac{g_a e_{a,j}}{z - g_a} + O(x^{-2}) \right),
$$

where $g_a$ are the twist parameters. The expansion of \ref{eq:3.19} is

$$
\hat{\psi}(x, z) = c_0(z) z^{x/\eta} \left( 1 - \frac{\eta}{x} \text{tr} \frac{Z_0}{z 1 - Z_0} + O(x^{-2}) \right).
$$

Equating the $O(1/x)$ terms of the two expansions leads to the relation

$$
\text{tr} \frac{Z_0}{z 1 - Z_0} = \sum_i \sum_a \frac{e_{a,i} g_a}{z - g_a}
$$

which has to be valid identically. Let us stress that its left hand side is well-defined because the entries of the matrix $Z_0$ are commuting operators. Using the identity $\text{tr} (z 1 - A)^{-1} = \partial_z \log \det (z 1 - A)$ valid for any matrix $A$, we integrate \ref{eq:4.1} to obtain

$$
\det (z 1 - Z_0) = \prod_{a=1}^{K} (z - g_a)^{M_a},
$$

where $M_a$ are the weight operators \ref{eq:2.17}. Since the time evolution is an isospectral deformation, the same is true for the Lax matrix $Z(t)$ for any values of the times. We see that $M_a$ is the “operator multiplicity” of the eigenvalue $g_a$. In the weight space $V(M_a)$ the multiplicities become equal to the $M_a$’s. The conclusion is:

- The Lax matrix $Z$ has eigenvalues $g_a$ with multiplicities $M_a \geq 0$ such that $M_1 + \ldots + M_N = L$.

Our next goal is to formulate the QC correspondence\textsuperscript{11} between the spin chains and the RS model.

### 4.2 The QC correspondence

Consider the Lax matrix $Z_0$ of the $L$-particle RS model, where the inverse “velocity of light”, $\eta$, is identified with the parameter $\eta$ introduced in the quantum $R$-matrix \ref{eq:2.2}, and the initial coordinates and velocities of the particles are identified, respectively, with the inhomogeneity parameters $x$ and eigenvalues of the Hamiltonians $H_i$ through

\textsuperscript{11} The QC correspondence can be traced back to [53], where joint spectra of some commuting finite-dimensional operators were linked to the classical Toda chain.
\[ x_i = -\eta H_i: \]

\[
Z_0 = \begin{pmatrix}
H_1 & \frac{\eta H_1}{x_2-x_1+\eta} & \frac{\eta H_1}{x_3-x_1+\eta} & \cdots & \frac{\eta H_1}{x_L-x_1+\eta} \\
\frac{\eta H_2}{x_1-x_2+\eta} & H_2 & \frac{\eta H_2}{x_3-x_2+\eta} & \cdots & \frac{\eta H_2}{x_L-x_2+\eta} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\frac{\eta H_L}{x_1-x_L+\eta} & \frac{\eta H_L}{x_2-x_L+\eta} & \frac{\eta H_L}{x_3-x_L+\eta} & \cdots & H_L
\end{pmatrix}.
\]  

(4.3)

According to the conclusion of the previous subsection, we claim that if the \( H_i \)'s are eigenvalues of the Hamiltonians of the spin chain in the weight space \( V(M_a) \subset \mathcal{V} \), then

\[
\text{Spec} \left( Z_0 \right) = \left( g_1, \ldots, g_1, g_2, \ldots, g_2, \ldots, g_K, \ldots, g_K \right).
\]  

(4.4)

Equivalently, let \( \mathcal{H}_j = \text{tr} (Z_0^j) \) be the higher integrals of motion of the RS model (see Appendix B), then their level set is defined by \( \mathcal{H}_j = \sum_{a=1}^{K} M_a g_a^j \). In general, the matrix \( Z_0 \) with multiple eigenvalues is not diagonalizable and contains Jordan cells.

One can also say that the eigenstates of the quantum Hamiltonians correspond to the intersection points of two Lagrangian submanifolds in the phase space of the RS model. One of them is the hyperplane defined by fixing all the coordinates \( x_i \) while the other one is the Lagrangian submanifold obtained by fixing values of the \( L \) independent integrals of motion in involution \( \mathcal{H}_k, k = 1, \ldots, L \). In general, there are many intersection points numbered by a finite set \( \mathcal{I} \), with coordinates, say \( (x_1, \ldots, x_L, p_1^{(\alpha)}, \ldots, p_L^{(\alpha)}) \), \( \alpha \in \mathcal{I} \). The values of \( p_j^{(\alpha)} \) give, through equation (B2), the spectrum of \( \mathcal{H}_j \):

\[
H_j^{(\alpha)} = e^{-\eta p_j^{(\alpha)}} \prod_{k=1, k \neq j}^{L} \frac{x_j - x_k + \eta}{x_j - x_k}.
\]

However, we can not claim that all the intersection points correspond to the energy levels of the Hamiltonians for a given spin chain. The examples elaborated below suggest that the set of the intersection points contains the points corresponding to spectra of the Hamiltonians for spin chains with different grading.

Summarizing, we claim that the spectral problem for the non-local inhomogeneous susy-XXX spin chain Hamiltonians \( \mathcal{H}_j \) in the subspace \( \mathcal{V}(\{M_a\}) \) is closely linked to the following inverse spectral problem for the RS Lax matrix \( Z_0 \) of the form (4.3). Let us fix the spectrum of the matrix \( Z_0 \) to be \( (4.4) \), where \( g_1, \ldots, g_K \) are eigenvalues of the (diagonal) twist matrix \( g \). Then we ask what is the set of possible values of the \( H_j \)'s allowed by these constraints. The eigenvalues \( H_j \) of the quantum Hamiltonians are contained in this set.
4.3 Algebraic equations for the spectrum

The characteristic polynomial of the matrix (4.3) can be found explicitly using the simple fact from the linear algebra that the coefficient in front of $z^{L-k}$ in the polynomial

$$\det_{L \times L}(z1 + A)$$

equals the sum of all diagonal $k \times k$ minors of the matrix $A$. All such minors can be found using the decomposition $Z_0 = -HQ$, where $H = \text{diag} (H_1, H_2, \ldots, H_L)$ and

$$Q_{ij} = \frac{\eta}{x_i - x_j - \eta} \quad (4.5)$$

is the Cauchy matrix, and the explicit expression for the determinant of the Cauchy matrix:

$$\det_{L \times L}(z1 - Z_0) = \det_{L \times L}(z1 + HQ) = \sum_{n=0}^{L} J_n z^{L-n}, \quad (4.6)$$

where

$$J_n = (-1)^n \sum_{1 \leq i_1 < \ldots < i_n \leq L} H_{i_1} \ldots H_{i_n} \prod_{1 \leq \alpha < \beta \leq n} \left( 1 - \frac{\eta^2}{(x_{i_\alpha} - x_{i_\beta})^2} \right)^{-1}. \quad (4.7)$$

In particular, the highest coefficient is given by the following simple formula:

$$J_L = (-1)^L H_1 H_2 \ldots H_L \prod_{1 \leq i < j \leq L} \left( 1 - \frac{\eta^2}{(x_i - x_j)^2} \right)^{-1}. \quad (4.8)$$

Let us point out that the integrals $\mathcal{H}_k$ introduced in the previous section are connected with the integrals $\mathcal{J}_k$ by the Newton’s formula \cite{32}: \( \sum_{k=0}^{L} \mathcal{J}_{L-k} \mathcal{H}_k = 0 \) (we have set $\mathcal{H}_0 = \text{tr}(Z)^0 = L$).

Combining (4.4) and (4.7), we see that the eigenvalues $H_i$ of the inhomogeneous susy-XXX Hamiltonians can be found from the system of polynomial equations

$$\sum_{1 \leq i_1 < \ldots < i_n \leq L} H_{i_1} \ldots H_{i_n} \prod_{1 \leq \alpha < \beta \leq n} \left( 1 - \frac{\eta^2}{(x_{i_\alpha} - x_{i_\beta})^2} \right)^{-1} = C_n(\{M_a\}), \quad (4.9)$$

where $n = 1, 2, \ldots, L$ and

$$C_n(\{M_a\}) = \frac{1}{2\pi i} \oint_{|z|=1} \prod_{a=1}^K (1 + zg_a)^{M_a} z^{-n-1} dz \quad (4.9)$$

There are $L$ equations for $L$ unknown quantities $H_1, \ldots, H_L$. Examples for small values of $L$ are given in the appendix.

Here we point out some simple general properties of these equations.
1. This system does not depend on $N|M$ and the grading parameters and is also invariant under the following transformations: a) $\eta \to -\eta$, b) $\{x_i\} \to \{-x_i\}$, c) $\{H_i\} \to \{-H_i\}$ simultaneously with $\{g_a\} \to \{-g_a\}$.

2. For $M_a = L\delta_{a1}$ (in this case $C_n = \frac{L!}{n!(L-n)!} g_{a1}^n$) there are two distinguished solutions

$$H_j = g_{a1} \prod_{k=1, k\neq j}^L \left( 1 \pm \frac{\eta}{x_j - x_k} \right)$$

(4.10)

which give the eigenvalues of the Hamiltonians on the vector $(v_{a1}) \circ L$. The two choices of sign correspond to two possible values of the grading parameter $p(a_1)$.

3. Assume that $L \leq K$ and fix $\{a_1, \ldots, a_L\} \subseteq \{1, \ldots, K\}$ such that all the $a_i$’s are distinct. Set $M_a = \sum_{i=1}^L \delta_{a,i}$, then the right hand sides of equations (4.8) are elementary symmetric polynomials

$$e_k(g_{a1}, \ldots, g_{aL})$$

of the twist parameters $g_{a1}, \ldots, g_{aL}$. Then the system of equations (4.8) has $L!$ solutions (counted with multiplicities). Indeed, at $\eta = 0$ the system is just

$$e_n(H_1, \ldots, H_L) = e_n(g_{a1}, \ldots, g_{aL}), \quad n = 1, \ldots, L$$

(4.11)

All solutions of this system are given by all possible permutations of the set $(g_{a1}, \ldots, g_{aL})$ containing $L$ elements.

The detailed structure of solutions to (4.8) and their correspondence with spectra of particular spin chains is a subject of further study. Some examples are discussed in Appendix C.

One can consider the system (4.8) with the right hand sides being “in general position” meaning that there are $L$ twist parameters $g_i$ which are all distinct. This is the generic situation from which all other possible cases can be obtained by merging some of the twist parameters. The generic system (4.8) contains $L$ equations of the form

$$\sum_{1 \leq i_1 < \ldots < i_n \leq L} H_{i_1} \cdots H_{i_n} \prod_{1 \leq \alpha < \beta \leq n} \left( 1 - \frac{\eta^2}{(x_{i_{\alpha}} - x_{i_{\beta}})^2} \right)^{-1} = e_n(g_1, \ldots, g_L).$$

(4.12)

The complete information about spectra of the Hamiltonians for $L$-site spin chains based on all (super)algebras of the type $gl(N|M)$ is contained in the universal spectral variety

$$\mathcal{S}_L = \left\{ (H_1, \ldots, H_L; x_1, \ldots, x_L; g_1, \ldots, g_L) \mid \text{Equations (4.12)} \right\}.$$  

(4.13)

It is a $2L$-dimensional affine variety embedded into $\mathbb{C}^{3L}$. The spectra of the Hamiltonians for particular spin chains are obtained by intersecting with the hyperplanes with fixed values of $x_i$’s and $g_i$’s. The variety $\mathcal{S}_L$ is not compact. We anticipate that a proper compactification of the universal spectral variety encodes information about the spectra of Hamiltonians for spin chains when some or all $x_i$’s coalesce.

---

12The elementary symmetric polynomials are defined by means of the generating function as follows:

$$\prod_{i=1}^N (1 + y_i z) = \sum_{k=0}^N e_k(y_1, \ldots, y_N) z^k.$$
5 The QC correspondence via nested Bethe ansatz

In this section we give a direct proof of the QC correspondence based on the nested Bethe ansatz solution to the susy-XXX spin chains.

5.1 Bethe ansatz solution for \(Y(gl(N|M))\) spin chain

Here we specify the general nested Bethe ansatz results (2.23), (2.27) for the spin chain with vector representations at the sites. The eigenstates of the T-operator \(T(x)\) are obtained from the reference state \((\psi_1) \otimes L\) with \(M_a = L\delta_{a1}\) by action of creation operators. In the weight space \(\mathcal{V}(M_1, \ldots, M_K)\) with \(M_1 = L - L_1, M_2 = L_1 - L_2, M_3 = L_2 - L_3, \ldots, M_{K-1} = L_{K-2} - L_{K-1}, M_K = L_{K-1}\) such that \(M_1 \geq M_2 \geq \ldots \geq M_K\) the eigenvalues of \(T(x)\) are given by the formula

\[
T(x) = (-1)^{\mu(1)}g_1 \prod_{l=1}^{L} \frac{x - x_l + (-1)^{\mu(1)}\eta}{x - x_l} \prod_{\alpha=1}^{L} \frac{x - \mu_1 - (-1)^{\mu(1)}\eta}{x - \mu_1}
\]

\[
+ \sum_{b=2}^{K} (-1)^{\mu(b)} \frac{gb}{a=1} \prod_{\alpha=1}^{L_{b-1}} \frac{x - \mu_{b-1} + (-1)^{\mu(b)}\eta}{x - \mu_{b-1}} \prod_{\alpha=1}^{L_b} \frac{x - \mu_b - (-1)^{\mu(b)}\eta}{x - \mu_b},
\]

(5.1)

where the parameters \(\mu_b\) (the Bethe roots) obey the system of Bethe equations

\[
gb \prod_{k=1}^{L} \frac{\mu_b - x_k - \delta_{b1}(-1)^{\mu(b)}\eta}{\mu_b - x_k} \prod_{\alpha=1}^{L_b} \frac{\mu_b - \mu_{b-1} + (-1)^{\mu(b)}\eta}{\mu_b - \mu_{b-1}}
\]

\[
= gb+1 \prod_{\alpha=1}^{L_b+1} \frac{\mu_b - \mu_{\gamma} + (-1)^{\mu(b+1)}\eta}{\mu_b - \mu_{\gamma}} \prod_{\alpha=1}^{L_{b+1}} \frac{\mu_b - \mu_{b+1} - (-1)^{\mu(b+1)}\eta}{\mu_b - \mu_{b+1}},
\]

(5.2)

Here \(b\) runs from 1 to \(K - 1 = N + M - 1\) and the convention \(L_0 = L_K = 0\) is implied. Note that at \(b = N\) (and \(M \neq 0\)) the first product in the r.h.s. of (5.2) disappears since \((-1)^{\mu(N)} = 1\) while \((-1)^{\mu(N+1)} = -1\). The Bethe equations are equivalent to the conditions that \(T(x)\) given by (5.1) is regular at the points \(x = \mu_b\) for all \(\beta = 1, \ldots, L_b, \ b = 1, \ldots, K-1\). The corresponding eigenvalues of the Hamiltonians \(H_i\) are

\[
H_i\{(x_i)_{L_1}, \{\mu_{\alpha}^1\}_{L_1}, g_1\} = g_1 \prod_{k=1}^{L_1} \frac{x_i - x_k + (-1)^{\mu(1)}\eta}{x_i - x_k} \prod_{\alpha=1}^{L_1} \frac{x_i - \mu_1 - (-1)^{\mu(1)}\eta}{x_i - \mu_1},
\]

(5.3)

where \(\{x_i\}_L\) emphasizes the dependence on \(L\) variables \(x_i\) (\(\{x_i\}_L\) means \(\{x_i\}_{i=1}^{L}\), in particular, \(\{x_i\}_0 = 0\) and similarly for \(\{\mu_{\alpha}^1\}_{L_1}\).

Example: \(N + M = 2\). In the weight space \(\mathcal{V}(M_1, M_2)\) with \(M_1 \geq M_2\) the Bethe equations are:

\[
gl(2|0) : g_1 \prod_{k=1}^{L} \frac{\mu_1 - x_k + \eta}{\mu_1 - x_k} = g_2 \prod_{\alpha \neq 1}^{M_2} \frac{\mu_1 - \mu_1 + \eta}{\mu_1 - \mu_1 - \eta},
\]

(5.4)
\[ gl(1|1) : \quad g_1 \prod_{k=1}^{L} \frac{\mu_1^1 - x_k + \eta}{\mu_1^1 - x_k} = g_2, \quad (5.5) \]

\[ gl(0|2) : \quad g_1 \prod_{k=1}^{L} \frac{\mu_1^1 - x_k - \eta}{\mu_1^0 - x_k} = g_2 \prod_{\gamma \neq \alpha}^{M_2} \frac{\mu_1^1 - \mu_1^\gamma - \eta}{\mu_1^0 - \mu_1^\gamma + \eta}. \quad (5.6) \]

where \( \alpha = 1, \ldots, M_2 \). Note that the equations for \( gl(0|2) \) are obtained from those for \( gl(2|0) \) by the transformation \( \eta \rightarrow -\eta \). The spectrum is given by (5.3) with \( p(1) = 0 \) for \( gl(2|0) \), \( gl(1|1) \):

\[ H_i = g_1 \prod_{k=1}^{L} \frac{x_i - x_k + \eta}{x_i - x_k} \prod_{\gamma=1}^{M_2} \frac{x_i - \mu_1^\gamma - \eta}{x_i - \mu_1^\gamma + \eta}, \quad (5.7) \]

and \( p(1) = 1 \) for \( gl(0|2) \) which leads to the same expression with \( \eta \rightarrow -\eta \).

### 5.2 The QC correspondence: a direct proof

Here we extend the result of [21] to supersymmetric spin chains.

**Theorem 5.1** Substitute

\[ \dot{x}_i = -\eta H_i (\{x_i\}_L, \{\mu_1^\alpha\}_{L_1}, g_1), \quad i = 1, \ldots, L \quad (5.8) \]

into the Lax matrix for the RS model (3.7), i.e. consider the matrix

\[ (Z_0)_{ij} = \frac{\eta H_i}{x_j - x_i + \eta} \quad (5.9) \]

(see (4.3)), where \( H_j \) are eigenvalues (5.3) of the non-local Hamiltonians of the inhomogeneous graded \( gl(N|M) \) spin chain on \( L \)-sites with \( N + M = K \leq L \) and the set \( \{\mu_1^\alpha\}_{L_1} \) is taken from any solution \( \{\mu_1^b\}_{L_b}, b = 1, \ldots, K - 1 \) of the Bethe equations (5.2). Then the spectrum of the Lax matrix (5.9) is of the form (4.4):

\[ \text{Spec } Z_0 \bigg|_{BE} = \left\{ \begin{array}{c}
g_1, \ldots, g_1, \quad g_2, \ldots, g_2, \ldots, g_{K-1}, \ldots, g_{K-1}, \quad g_K, \ldots, g_K \end{array} \right\}. \quad (5.10) \]

**Proof.** The proof involves three steps. First, we recall the proof for the \( gl(K|0) \) case. Next, we show how to modify it for the \( gl(0|K) \) case. Lastly, the general case is processed by gluing together the previous two proofs in a proper way.

Instead of \( Z_0 \) it is more convenient to deal with the transposed Lax matrix \( Z^*_0 \) given by

\[ (Z^*_0)_{ij}(\{\dot{x}_k\}_L, \{x_k\}_L, \eta) = -\frac{\dot{x}_j}{x_i - x_j + \eta} = \frac{\eta H_j}{x_i - x_j + \eta}, \quad i, j = 1, \ldots, L. \quad (5.11) \]

Its spectrum coincides with that of \( Z_0 \).
1. \( gl(K|0) \) case. The proof given in [21] is based on the identity

\[
\det_{L \times L} \left( Z \left( \{x_i\}_L, \{y_i\}_L, g \right) - \lambda 1 \right) = (g - \lambda)^{L - \tilde{L}} \det_{\tilde{L} \times \tilde{L}} \left( \tilde{Z} \left( \{y_i\}_L, \{x_i\}_L, g \right) - \lambda 1 \right) \tag{5.12}
\]

for the pair of \( L \times L \) and \( \tilde{L} \times \tilde{L} \) matrices

\[
\mathcal{Z}_{ij}(\{x_k\}_L, \{y_k\}_L, g) = \frac{g \eta}{x_i - x_j + \eta} \prod_{k \neq j}^{L} \frac{x_j - x_k + \eta}{x_j - x_k} \prod_{\gamma = 1}^{\tilde{L}} \frac{x_j - y_\gamma + \eta}{x_j - y_\gamma} \tag{5.13}
\]

and

\[
\tilde{\mathcal{Z}}_{\alpha\beta}(\{y_i\}_L, \{x_i\}_L, g) = \frac{g \eta}{y_\alpha - y_\beta + \eta} \prod_{\gamma \neq \beta}^{\tilde{L}} \frac{y_\beta - y_\gamma - \eta}{y_\beta - y_\gamma} \prod_{k = 1}^{L} \frac{y_\beta - x_k - \eta}{y_\beta - x_k} \tag{5.14}
\]

(here \( L \geq \tilde{L} \)). In addition, we have

\[
\det_{L \times L} \left( \mathcal{Z}^0 \left( \{x_i\}_L, g \right) - \lambda 1 \right) = \det_{L \times L} \left( \tilde{\mathcal{Z}}^0 \left( \{y_i\}_L, g \right) - \lambda 1 \right) = (g - \lambda)^L, \tag{5.15}
\]

where

\[
\mathcal{Z}_{ij}^0(\{x_k\}_L, g) = \mathcal{Z}_{ij}(\{x_k\}_L, \{y_k\}_0, g) = \frac{g \eta}{x_i - x_j + \eta} \prod_{k \neq j}^{L} \frac{x_j - x_k + \eta}{x_j - x_k} \tag{5.16}
\]

and

\[
\tilde{\mathcal{Z}}_{\alpha\beta}^0(\{y_k\}_L, g) = \tilde{\mathcal{Z}}_{\alpha\beta}(\{y_k\}_L, \{x_k\}_0, g) = \frac{g \eta}{y_\alpha - y_\beta + \eta} \prod_{\gamma \neq \beta}^{\tilde{L}} \frac{y_\beta - y_\gamma - \eta}{y_\beta - y_\gamma}. \tag{5.17}
\]

The idea is to calculate \( \det(\mathcal{Z}_0 - \lambda 1) \) by sequential usage of the identity (5.12) (which allows one to pass to a smaller matrix) and the Bethe equations (BE) (5.2) with \( p(b) = 0 \) for all \( b \). Schematically\(^{13}\), the procedure of the proof is as follows:

\[
\langle \mathcal{Z}_0^\epsilon \rangle \left( -\eta \{H_j\}_L, \{x_j\}_L, \eta \right) \equiv \langle \mathcal{Z} \rangle \left( \{x_i - \eta\}_L, \{\mu_1\}_L, \{1\}_L, g_1 \right) \tag{5.12}
\]

\[
\langle \mathcal{Z} \rangle \left( \{\mu_1\}_L, \{x_i - \eta\}_L, g_1 \right) \overset{\text{BE}_{b=1}}{=} \langle \mathcal{Z} \rangle \left( \{\mu_1 - \eta\}_L, \{\mu_2\}_L, g_2 \right) \tag{5.18}
\]

\[
\langle \mathcal{Z} \rangle \left( \{\mu_2\}_L, \{\mu_1 - \eta\}_L, g_2 \right) \overset{\text{BE}_{b=2}}{=} \langle \mathcal{Z} \rangle \left( \{\mu_2 - \eta\}_L, \{\mu_3\}_L, g_3 \right) \tag{5.12}
\]

Each time we use (5.12) the characteristic polynomial \( \det(\mathcal{Z} - \lambda 1) \) acquires the factor \( (g_b - \lambda)^{L_b - 1 - L_b} \) except for the last step when we use (5.15) to get \( (g_K - \lambda)^{L_K - 1} \).

\(^{13}\)Here we symbolically write simply \( \langle \mathcal{Z} \rangle \) for the characteristic polynomial \( \det(\mathcal{Z} - \lambda 1) \) with some overall factor.
2. \( gl(0|K) \) case. It is easy to see that this case is similar to the previous one but the roles of \( Z \) and \( \tilde{Z} \) in the scheme (5.18) get interchanged:

\[
\langle Z_0^\lambda \ (-\eta \{ H_j \}_{L}, \{ x_j \}_{L}, \eta \rangle \overset{5.3}{=} \langle \tilde{Z} \rangle (\{ x_i + \eta \}_{L}, \{ \mu_i^L \}_{L^1}, g_1) \overset{5.12}{=} \langle \tilde{Z} \rangle (\{ \mu_i^L \}_{L^1}, \{ x_i + \eta \}_{L}, g_1) BE_{\eta=1} \langle \tilde{Z} \rangle (\{ \mu_i^L \}_{L^2}, \{ \mu_i^2 \}_{L_2}, g_2) \overset{5.12}{=} \langle \tilde{Z} \rangle (\{ \mu_i^2 \}_{L_2}, \{ \mu_i^L \}_{L^2}, g_2) \overset{5.12}{=} \langle \tilde{Z} \rangle (\{ \mu_i^2 \}_{L_3}, \{ \mu_i^3 \}_{L_3}, g_3) \overset{5.12}{=} \ldots
\]

Here we use the BE (5.2) with \( p(b) = 1 \) for all \( b \).

3. \( gl(N|M) \) case. We assume that \( N, M \geq 1 \). The scheme (5.18) works for \( b = 1, \ldots, N-1 \) while (5.19) does for \( b = N+1, \ldots, N+M \). In order to switch from the scheme (5.18) to (5.19) we need an intermediate step. It is accomplished by the BE (5.2) at \( b = N \):

\[
BE_{\eta=N} : \quad g_N \prod_{\gamma=1}^{L_N-1} \frac{\mu_{\beta}^\gamma - \mu_{\gamma}^N - \eta}{\mu_{\beta}^\gamma - \mu_{\gamma}^N + \eta} = g_{N+1} \prod_{\gamma=1}^{L_{N+1}} \frac{\mu_{\beta}^N - \mu_{\gamma}^{N+1} + \eta}{\mu_{\beta}^N - \mu_{\gamma}^{N+1} - \eta} .
\]

Then for

\[
\langle \tilde{Z} \rangle (\{ \mu_i^N \}_{L_N}, \{ \mu_i^{N-1} - \eta \}_{L_{N-1}}, g_N)
\]

we have:

\[
\langle \tilde{Z} \rangle (\{ \mu_i^N \}_{L_N}, \{ \mu_i^{N-1} - \eta \}_{L_{N-1}}, g_N) \overset{5.20}{=} \langle \tilde{Z} \rangle (\{ \mu_i^N + \eta \}_{L_N}, \{ \mu_i^{N+1} \}_{L_{N+1}}, g_{N+1}) .
\]

This finishes the proof.

**Appendix A: The higher T-operators through super-characters**

Here we show how to derive (2.32). We have:

\[
T_\lambda(x) = \text{str}_{V_\lambda} \left[ \left( I + \frac{\eta}{x-x_L} P_{\lambda}^{0L} \right) \cdots \left( I + \frac{\eta}{x-x_2} P_{\lambda}^{02} \right) \left( I + \frac{\eta}{x-x_1} P_{\lambda}^{01} \right) (\pi_\lambda(g) \otimes I) \right]
\]

\[
= \text{str}_{V_\lambda} \pi_\lambda(g) I + \sum_j \frac{\eta}{x-x_j} \text{str}_{V_\lambda} \left( P_{\lambda}^{0j} (\pi_\lambda(g) \otimes I) \right) + \sum_{i<j} \frac{\eta^2}{(x-x_i)(x-x_j)} \text{str}_{V_\lambda} \left( P_{\lambda}^{0j} P_{\lambda}^{0i} (\pi_\lambda(g) \otimes I) \right)
\]

\[
+ \ldots + \frac{\eta^L}{(x-x_1) \ldots (x-x_L)} \text{str}_{V_\lambda} \left( P_{\lambda}^{0j} \cdots P_{\lambda}^{01} (\pi_\lambda(g) \otimes I) \right).
\]

Plugging here the explicit form of \( P_{\lambda}^{0j} \) (2.9), we get:

\[
T_\lambda(x) = \text{str}_{V_\lambda} \pi_\lambda(g) I + \sum_j \sum_{ab} \frac{\eta (-1)^{p(b)} e_{ba}^{(j)}}{x-x_j} \text{str}_{V_\lambda} \left( \pi_\lambda(e_{ab}) \pi_\lambda(g) \right)
\]

32
The last step is based on the following simple lemma:

**Lemma A1.** Let \( \pi \) be a representation of \( U(gl(N|M)) \), \( \chi \) its character and \( h_1, h_2, \ldots, h_n \) be any homogeneous elements of the superalgebra \( gl(N|M) \) such that \([h_i, h_i] = 0\) (here \([ , ]\) means the graded commutator). Then for any group element \( g \in GL(N|M) \) it holds:

\[
\text{str} \left[ \pi(h_1) \pi(h_2) \ldots \pi(h_n) \pi(g) \right] = \frac{\partial}{\partial \varepsilon_n} \ldots \frac{\partial}{\partial \varepsilon_1} \chi(\varepsilon_1 h_1 \ldots \varepsilon_n h_n g) \bigg|_{\varepsilon_i = 0} ,
\]

where it is implied that \( p(\varepsilon_i) = p(h_i) \).

The proof is simple. Since \([h_i, h_i] = 0\), the exponents \( \varepsilon_i h_i \) are supergroup elements for any \( \varepsilon_i \). Therefore, we have the chain of equalities

\[
\pi(\varepsilon_1 h_1 \ldots \varepsilon_n h_n g) = \prod_{j=1}^{\varepsilon_n} \pi(\varepsilon_j h_j) \pi(g) = \prod_{j=1}^{\varepsilon_n} e^{\varepsilon_j \pi(h_j)} \pi(g),
\]

from which it follows directly that

\[
\pi(h_1) \pi(h_2) \ldots \pi(h_n) \pi(g) = \frac{\partial}{\partial \varepsilon_n} \ldots \frac{\partial}{\partial \varepsilon_1} \pi(\varepsilon_1 h_1 \ldots \varepsilon_n h_n g) \bigg|_{\varepsilon_i = 0} .
\]

Taking supertrace of the both sides, we obtain (A1). Applying the lemma to the case \( h_i = e_{a_i b_i} \), we arrive at (2.32).

**Appendix B: Hamiltonian formulation of the RS model**

For completeness, we give here the Hamiltonian formulation of the \( L \)-particle RS model, including the higher flows. The Hamiltonian is

\[
\mathcal{H}_1 = \sum_{i=1}^{L} e^{-\eta p_i} \prod_{k=1, k \neq i}^{L} \frac{x_i - x_k + \eta}{x_i - x_k} ,
\]

with \( \{p_i, x_i\} \) being the canonical variables with the standard Poisson brackets. The Hamiltonian equations of motion \( \begin{pmatrix} \dot{x}_i \\ \dot{p}_i \end{pmatrix} = \begin{pmatrix} \partial_{p_i} \mathcal{H}_1 \\ -\partial_{x_i} \mathcal{H}_1 \end{pmatrix} \) give the connection between velocity and momentum

\[
\dot{x}_i = -\eta e^{-\eta p_i} \prod_{k=1, k \neq i}^{L} \frac{x_i - x_k + \eta}{x_i - x_k} \quad (B2)
\]
and the equations of motion (3.11).

The RS model is known to be integrable, with the higher integrals of motion in involution being given by $H_k = \text{tr} Z_k$, where $Z$ is the Lax matrix of the model (3.7):

$$Z_{ij} = \dot{x}_i - x_i - x_j - \eta = \eta e^{-\eta p_i} \prod_{k=1, \neq i}^L \left(1 + \frac{\eta}{x_i - x_k}\right).$$

(B3)

These integrals of motion can be regarded as Hamiltonians generating flows in the “higher times” $t_k$ via the Hamiltonian equations

$$\left(\begin{array}{c}
\partial_{t_k} x_i \\
\partial_{t_k} p_i
\end{array}\right) = \left(\begin{array}{c}
\partial_{p_i} H_k \\
-\partial_i H_k
\end{array}\right), \quad k \geq 1.$$  

(B4)

Moreover, the dynamics in the higher time $t_k$ is precisely the one induced by the mKP flow on the roots of the tau function (3.1). The fact that the integrals of motion $H_k$ are in involution agrees with the commutativity of the mKP flows. The proof is based on the linear problems (3.6), (3.14) and general relation (2.59). We will not repeat it here since it is technically involved. It can be found in [17, 8].

### Appendix C: Examples for small values of $L$ and limiting cases

$L = 1$. For $L = 1$, $T(\square)(x) = (\text{str} \ g)1 + \frac{\eta}{x-x_1} \sum_{a=1}^{K} g_a e_{aa}$ and $H_1 = \sum_{a=1}^{K} g_a e_{aa} = g$. This case is trivial because there is only one Hamiltonian which is already diagonal. The system (1.8) is in a trivial agreement with this: it states that $H_1 = g_a$. The master T-operator has the form

$$e^{-\text{str} \xi(t,g)} \left| \frac{T(x,t)}{T(\theta)(x)} \right|_{L=1} = I + \eta \sum_{k \geq 1} \frac{kt_k(g^{(1)})^k}{x-x_1}.$$  

(C1)

$L = 2$. The case $L = 2$ is more interesting. We have: $g = g_1 e_{11} + g_2 e_{22}$,

$$T(\square)(x) = (\text{str} \ g)1 \otimes 1 + \frac{\eta}{x-x_1} g \otimes 1 + \frac{\eta}{x-x_2}$$

$$+ \frac{\eta^2}{(x-x_1)(x-x_2)} \sum_{a,b=1}^{K} (-1)^{p(a)p(b)} g_b e_{ba} \otimes e_{ab}.$$  

(C2)

It is convenient to work in the basis $v_a \otimes v_b$ of the space $\mathcal{V} = \mathbb{C}^{N|M} \otimes \mathbb{C}^{N|M}$. The Hamiltonians act as follows:

$$H_1 v_a \otimes v_b = g_a v_a \otimes v_b + \frac{(-1)^{p(a)p(b)} \eta g_b}{x_1 - x_2} v_b \otimes v_a,$$

(C3)

$$H_2 v_a \otimes v_b = g_b v_a \otimes v_b + \frac{(-1)^{p(a)p(b)} \eta g_b}{x_2 - x_1} v_b \otimes v_a,$$

(C4)
where we have used the rule
\[(e_{cd} \otimes e_{dc})(v_a \otimes v_b) = (-1)^{p(e_{dc})}p(v_a)e_{cd}v_a \otimes e_{dc}v_b = (-1)^{(p(d)+p(c))p(a)}\delta_{da}\delta_{cb}v_c \otimes v_d.\]

Therefore, eigenvalues of \(H_1\) in the subspace of \(V\) spanned by the vectors \(v_{a_1} \otimes v_{a_2}\) and \(v_{a_2} \otimes v_{a_1}\) with some fixed \(a_1 \neq a_2\) are given by diagonalizing the \(2 \times 2\) matrix

\[
\begin{pmatrix}
  g_{a_1} & (-1)^{p(a_1)p(a_2)}\eta g_{a_2} \\
  x_1 - x_2 & x_1 - x_2 \\
\end{pmatrix}
\]

Then the spectrum of the operators \((H_1, H_2)\) is

\[
(H_1, H_2) = \left( g_{a_1} + \frac{(-1)^{p(a_1)}\eta g_{a_1}}{x_1 - x_2}, g_{a_1} + \frac{(-1)^{p(a_1)}\eta g_{a_1}}{x_2 - x_1} \right)
\]

in \(Cv_{a_1} \otimes v_{a_1}\) \((M_a = 2\delta_{aa_1})\), \(\qquad \) (C5)

\[
(H_1, H_2) = \left( \frac{g_{a_1} + g_{a_2} + \sqrt{R}}{2}, \frac{g_{a_1} + g_{a_2} - \sqrt{R}}{2} \right), \left( \frac{g_{a_1} + g_{a_2} - \sqrt{R}}{2}, \frac{g_{a_1} + g_{a_2} + \sqrt{R}}{2} \right)
\]

in \(Cv_{a_1} \otimes v_{a_2} + Cv_{a_2} \otimes v_{a_1}\) for \(a_1 \neq a_2\) \((M_a = \delta_{aa_1} + \delta_{aa_2})\). \(\) (C6)

Here \(R = (g_{a_1} - g_{a_2})^2 + 4\eta^2 g_{a_1} g_{a_2}(x_1 - x_2)^2\) and \(1 \leq a_1, a_2 \leq K\) are some fixed indices.

Let us compare these results with solutions of the system (4.8) which in our case reduces to

\[
\begin{cases}
H_1 + H_2 = 2g_{a_1} \\
H_1H_2 = g_{a_1}^2 \left(1 - \frac{\eta^2}{(x_1 - x_2)^2}\right) & \text{for } M_a = 2\delta_{aa_1}
\end{cases}
\]

and

\[
\begin{cases}
H_1 + H_2 = g_{a_1} + g_{a_2} \\
H_1H_2 = g_{a_1}g_{a_2} \left(1 - \frac{\eta^2}{(x_1 - x_2)^2}\right) & \text{for } M_a = \delta_{aa_1} + \delta_{aa_2}.
\end{cases}
\]

Each system has two solutions for the pair \((H_1, H_2)\). One can easily check that the two solutions of the former system are just (C5) for the two possible values \(p(a_1) = 0, 1\) while the two solutions of the latter one are given by (C6).

The master T-operator has the form

\[
e^{-\text{str}(t, g)T(x, t)}|_{L=2} = I + \eta \sum_{i=1}^{2} \sum_{k \geq 1} \frac{kt_k(g^{(i)})^k}{x - x_i} + \frac{\eta^2}{(x - x_1)(x - x_2)} \times \left[ \sum_{k_1 \geq 1} k_1t_{k_1}(g^{(1)})^{k_1} \right] \left[ \sum_{k_2 \geq 1} k_2t_{k_2}(g^{(2)})^{k_2} \right] + \sum_{k \geq 1} k^\alpha \sum_{\alpha = 0}^{k-1} P_1^2(g^{(1)})\alpha(g^{(2)})^{k-\alpha}\right]. \) \ \ (C7)

\(L = 3\). We start with the explicit form of the Hamiltonians \(H_i\). Let us introduce the short-hand notation \(p_i := (-1)^{p(a_i)}, p_{ij} := (-1)^{p(a_i)p(a_j)}\). In the 3-dimensional subspace
spanned by the vectors $v_{a_1} \otimes v_{a_1} \otimes v_{a_2}$, $v_{a_1} \otimes v_{a_2} \otimes v_{a_1}$ and $v_{a_2} \otimes v_{a_1} \otimes v_{a_1}$ for $a_1 \neq a_2$, we have

$$H_1 = \begin{pmatrix} g_{a_1} \left( \frac{\eta_{11}^2}{x_{12}} + 1 \right) & \eta_{11}^2 g_{a_1} p_{12} & \eta_{11} g_{a_1} p_{12} & 0 \\ 0 & g_{a_1} \left( \frac{\eta_{13}^2}{x_{13}} + 1 \right) & \eta_{13} g_{a_1} p_{12} & 0 \\ \eta_{a_2}(x_{12} p_{11} + \eta) & 0 & g_{a_2} & 0 \end{pmatrix}, \quad \text{(C8)}$$

$$H_2 = \begin{pmatrix} g_{a_1} \left( \frac{\eta_{12}^2}{x_{12}} + 1 \right) & 0 & \eta_{12} g_{a_1} p_{12} & 0 \\ \eta_{a_2}(x_{12} p_{11} + \eta) & g_{a_2} & 0 & 0 \\ 0 & 0 & g_{a_1} \left( \frac{\eta_{13}^2}{x_{13}} + 1 \right) & 0 \end{pmatrix}, \quad \text{(C9)}$$

$$H_3 = \begin{pmatrix} 0 & -\eta_{a_2} g_{a_1} p_{12} & 0 & 0 \\ \eta_{a_2}(x_{13} p_{11} - \eta) & 0 & g_{a_2} & 0 \\ 0 & 0 & g_{a_1} \left( \frac{\eta_{12}^2}{x_{12}} + 1 \right) & 0 \end{pmatrix}. \quad \text{(C10)}$$

In the 6-dimensional subspace spanned by the vectors $\{v_{a_r(1)} \otimes v_{a_r(2)} \otimes v_{a_r(3)}\}_{r \in S_3}$, where $S_3$ is the permutation group over $\{1, 2, 3\}$ and $a_i \neq a_j$ if $i \neq j$, we have

$$H_1 = \begin{pmatrix} \eta_{a_2} p_{12} & 0 & \eta_{a_2} p_{12} & 0 & \eta_{a_2} p_{12} & \eta_{a_2} p_{12} & \eta_{a_2} p_{12} \\ 0 & \eta_{a_2} p_{12} & 0 & \eta_{a_2} p_{12} & 0 & \eta_{a_2} p_{12} & 0 \\ \eta_{a_2} p_{12} & \eta_{a_2} p_{12} & 0 & \eta_{a_2} p_{12} & \eta_{a_2} p_{12} & 0 & 0 \\ \eta_{a_2} p_{12} & 0 & \eta_{a_2} p_{12} & \eta_{a_2} p_{12} & 0 & 0 & 0 \\ \eta_{a_2} p_{12} & 0 & \eta_{a_2} p_{12} & \eta_{a_2} p_{12} & 0 & 0 & 0 \\ \eta_{a_2} p_{12} & 0 & \eta_{a_2} p_{12} & \eta_{a_2} p_{12} & 0 & 0 & 0 \end{pmatrix}, \quad \text{(C11)}$$

$$H_2 = \begin{pmatrix} \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & 0 & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} \\ \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & 0 & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & 0 \\ \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & 0 & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & 0 \\ \eta_{a_2} p_{23} & 0 & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} \\ \eta_{a_2} p_{23} & 0 & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} \\ \eta_{a_2} p_{23} & 0 & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} & \eta_{a_2} p_{23} \end{pmatrix}, \quad \text{(C12)}$$
Here we show the spectra of the spin chains. In the case a) we have found the following sets of solutions

\[
\begin{pmatrix}
\eta_g a_1 P_{12} P_{23} & \eta g a_2 P_{23} & 0 & -\eta^2 g a_1 P_{12} P_{13} & 0 & \eta g a_1 P_{12} P_{13} P_{23} \\
\eta g a_1 P_{23} & \eta^2 g a_2 P_{12} P_{23} & x_{32} & 0 & \eta g a_1 P_{12} P_{13} P_{23} & 0 \\
0 & -\eta^2 g a_2 P_{12} P_{23} & x_{31} & 0 & \eta g a_1 P_{12} P_{13} P_{23} & 0 \\
0 & \eta g a_1 P_{12} P_{13} P_{23} & x_{31} & \eta^2 g a_2 P_{12} P_{23} & x_{32} & 0 \\
-\eta^2 g a_1 P_{12} P_{13} P_{23} & x_{31} & 0 & -\eta^2 g a_2 P_{12} P_{23} & x_{32} & 0 \\
\eta g a_1 P_{12} P_{23} & x_{31} & 0 & \eta g a_1 P_{12} P_{13} P_{23} & x_{32} & \eta g a_1 P_{12} P_{13} P_{23}
\end{pmatrix}
\]

(C13)

For general \( g_1, g_2, g_3 \) the analytic diagonalization of these matrices is not possible. However, it can be done numerically for any particular values of the parameters.

For \( L = 3 \) the system (4.13) looks as follows:

\[
\begin{align*}
H_1 + H_2 + H_3 &= C_1(\{M_a\}) \\
H_1 H_2 + H_2 H_3 + H_1 H_3 &= C_2(\{M_a\}) \\
H_1 H_2 H_3 &= C_3(\{M_a\})
\end{align*}
\]

(C14)

where \( x_{ij} \equiv x_i - x_j \),

\begin{align*}
C_1(\{M_a\}) &= \sum_{a=1}^{K} M_a g_a \\
C_2(\{M_a\}) &= \frac{1}{2} \left( \sum_{a=1}^{K} M_a g_a \right)^2 - \frac{1}{2} \sum_{a=1}^{K} M_a g_a^2 \\
C_3(\{M_a\}) &= \frac{1}{6} \left( \sum_{a=1}^{K} M_a g_a \right)^3 - \frac{1}{2} \left( \sum_{a=1}^{K} M_a g_a^2 \right) \left( \sum_{b=1}^{K} M_b g_b \right) + \frac{1}{3} \sum_{a=1}^{K} M_a g_a^3.
\end{align*}

and \( M_1 + \ldots + M_K = 3 \). Correspondingly, there are 3 possibilities:

a) \( M_a = 3 \delta_{a_1} \), then \( C_1 = 3 g_{a_1}, C_2 = 3 g_{a_1}^2, C_3 = g_{a_1}^3; \)

b) \( M_a = 2 \delta_{a_1} + \delta_{a_2} \) \((a_1 \neq a_2)\), then \( C_1 = 2 g_{a_1} + g_{a_2}, C_2 = 2 g_{a_1} g_{a_2} + g_{a_1}^2, C_3 = g_{a_1}^2 g_{a_2}; \)

c) \( M_a = \delta_{a_1} + \delta_{a_2} + \delta_{a_3} \) \((a_0 \neq a_2 \neq a_3), \)

then \( C_1 = g_{a_1} g_{a_2} + g_{a_3}, C_2 = g_{a_1} g_{a_2} + g_{a_1} g_{a_3} + g_{a_2} g_{a_3}, C_3 = g_{a_1} g_{a_2} g_{a_3}. \)

Here \( 1 \leq a_1, a_2, a_3 \leq K \) are 3 fixed indices.

It is instructive to solve the system and to figure out how the solutions correspond to the spectra of the spin chains. In the case a) we have found the following sets of solutions.
for the triple \((H_1, H_2, H_3)\):

\[
H_j = g_{a_1} \prod_{k=1 \atop k \neq j}^{3} \left( 1 \pm \frac{\eta}{x_{jk}} \right), \quad j = 1, 2, 3, \quad (C15)
\]

\[
H_\alpha = g_{a_1} \left( 1 + \frac{\eta^2 \pm \eta \sqrt{Q}}{2x_{\alpha\beta}x_{\gamma\alpha}} \right), \quad Q \equiv 2(x^2_{12} + x^2_{13} + x^2_{23}) - 3\eta^2, \quad (C16)
\]

where \(\{\alpha, \beta, \gamma\}\) in the second line stands for any cyclic permutation of \(\{1, 2, 3\}\). The multiplicity of each of the solutions \((C15)\) is 1 and that of \((C16)\) is 2 (thus there are \(2 \times 1 + 2 \times 2 = 6\) solutions in total). For the case b) with \(g_{a_1} = g_{a_2}\) or for the case c) with \(g_{a_1} = g_{a_2} = g_{a_3}\), the system of equations has exactly the same form as for the case a). Therefore, these three cases share the same sets of solutions.

Let us give a more detailed description based on the analytic solutions as well as on numerical calculations. By a solution of \((C14)\) we mean here the ordered set \((H_1, H_2, H_3)\).

In case a), \((M_1, M_2, M_3) = (3, 0, 0)\), there are 6 solutions. One of them (the one in \((C15)\) with plus) coincides with the eigenvalues of \((H_1, H_2, H_3)\) in the one-dimensional space \(\mathcal{V}(3, 0, 0)\) with the grading parameter \(p(1) = 0\). Another one (the one in \((C15)\) with minus) coincides with the eigenvalue in the space \(\mathcal{V}(3, 0, 0)\) but with the grading parameter \(p(1) = 1\) (that is the same as changing \(\eta \to -\eta\)). The rest 4 solutions \((C16)\) do not correspond to eigenvalues of \((H_1, H_2, H_3)\) in the same model if all the twist parameters are different. Instead, they can be found among the sets of eigenvalues in the 3-dimensional space \(\mathcal{V}(2, 1, 0)\) for the model with \(g_1 = g_2\) and \(p(1) = 0, 1\) or in the 6-dimensional space \(\mathcal{V}(1, 1, 1)\) for the model with \(g_1 = g_2 = g_3\) independently of the grading parameters.

In case b), \((M_1, M_2, M_3) = (2, 1, 0)\), among 6 solutions of \((C14)\), three coincide with three sets of eigenvalues of \((H_1, H_2, H_3)\) in the 3-dimensional space \(\mathcal{V}(2, 1, 0)\) with the grading parameter \(p(1) = 0\). The rest three solutions coincide with three sets of eigenvalues in the space \(\mathcal{V}(2, 1, 0)\) but with the grading parameter \(p(1) = 1\).

Lastly, in case c), \((M_1, M_2, M_3) = (1, 1, 1)\), the 6 solutions of \((C14)\) coincide with the 6 sets of eigenvalues of \((H_1, H_2, H_3)\) in the six-dimensional space \(\mathcal{V}(1, 1, 1)\). They do not depend on the grading parameters. It is the case of “general position”. The other cases can be obtained form it by a degeneration procedure. We conjecture that this is true for any \(L\).
The master T-operator for $L = 3$ has the form
\[
e^{-str \xi(t,g)} \left. \frac{T(x,t)}{T_0(x)} \right|_{L=3} = I + \eta \sum_{i=1}^{3} \sum_{k \geq 1} \frac{k t_k (g^{(i)})^k}{x - x_i} + \eta^2 \sum_{1 \leq i < j \leq 3} \frac{1}{(x - x_i)(x - x_j)} \times \left( \sum_{k_1 \geq 1} k_1 t_{k_1} (g^{(1)})^{k_1} \right) \left( \sum_{k_2 \geq 1} k_2 t_{k_2} (g^{(2)})^{k_2} \right) \left( \sum_{k_3 \geq 1} k_3 t_{k_3} (g^{(3)})^{k_3} \right) + \sum_{k \geq 1} k t_k \sum_{\alpha_2 = 0}^{k-1} P_{23}(g^{(2)})^{\alpha_2} (g^{(3)})^{k-\alpha_2} \left( \sum_{\alpha_1 = 0}^{\alpha_2-1} P_{12}(g^{(1)})^{\alpha_1} (g^{(2)})^{\alpha_2-\alpha_1} \right) (g^{(3)})^{k-\alpha_2} + \sum_{k \geq 1} k t_k \sum_{\alpha_2 = 0}^{k-1} P_{23}(g^{(2)})^{\alpha_2} \left( \sum_{\alpha_1 = 0}^{k-\alpha_2-1} P_{13}(g^{(1)})^{\alpha_1} (g^{(3)})^{k-\alpha_1-\alpha_2} \right) \right].
\]

(C17)

Limiting cases. There are two limits, where one can obtain the spectrum explicitly: \( \eta \to 0, \infty \). Here we assume that the twist parameters do not depend on \( \eta \). Thus, the limit \( \eta \to 0 \) discussed here differs from the one to the Gaudin model.

(i) \( \eta \to 0 \). The operator \( H_j^{(0)} = \lim_{\eta \to 0} H_j = g^{(j)} \) is diagonal in the basis \( v_{a_1} \otimes v_{a_2} \otimes \ldots \otimes v_{a_L} \). It has the eigenvalues \( g_{a_i} \). The degeneracy of each eigenvalue is \( K^{L-1} \).

The system of algebraic equations (4.8) degenerates into (4.11). The solutions of (4.11) correspond to this case if \( L \leq K \) and all the \( \{a_i\}_{i=1}^{L} \) are distinct. If some of \( M_i \)'s are bigger than 1 (this is always the case if \( L > K \)), then the eigenvalues of the Hamiltonians can be obtained by merging some of the twist parameters in (4.11). Such solutions of (4.11) also correspond to the above eigenvalues when some of the \( a_i \)'s or \( g_{a_i} \)'s coincide.

(ii) \( \eta \to \infty \). Consider the operator \( H_j^{(\infty)} = \lim_{\eta \to \infty} \eta^{-L} H_j \). It acts on the basis vectors
as follows (see (2.15)): 

\[ H_j^{(\infty)}(v_{a_1} \otimes v_{a_2} \otimes \ldots \otimes v_{a_L}) = \frac{(-1)^{p(a_L)} \sum_{k=1}^{L-1} p(a_k) g_{a_L}}{\prod_{k=1}^{L} (x_j - x_k)} (v_{a_L} \otimes v_{a_1} \otimes \ldots \otimes v_{a_{L-1}}). \] 

(C18)

Then we find that \( H_j^{(\infty)} \) has an eigenvector 

\[ \sum_{k=0}^{L-1} (-1)^{\frac{2a_k}{L}} \frac{2^{L-k}}{L \cdot \sum_{i=0}^{k-1} p(a_i(L))} \prod_{i=1}^{L} g_{a_k(i)} \bigg( v_{a_k(i)} \otimes \ldots \otimes v_{a_k(L)} \bigg) \] 

for each \( \alpha \in \{0, 1, \ldots, L-1\} \), where \( \sigma(i) = i - 1 \) for \( i \in \{2, 3, \ldots, L\} \), \( \sigma(1) = L \). The corresponding eigenvalue is 

\[ (-1)^{\frac{2a_k}{L}} \prod_{k=1}^{L} \frac{g_{a_k}}{x_j - x_k}. \] 

(C20)

Apparently, degeneracy of each eigenvalue is \((L-1)!\) if \( a_i \neq a_k \) for any \( i \neq k \). Note that the eigenvalue (C20) does not depend on the grading parameters, although the corresponding eigenvector (C19) does.

The system (4.8) in the limit \( \eta \to \infty \) reduces to 

\[ \sum_{1 \leq i_1 < \ldots < i_n \leq L} H_{i_1}^{(\infty)} \ldots H_{i_n}^{(\infty)} \prod_{\alpha=1}^{n} \prod_{\beta=1, \beta \neq \alpha}^{n} (x_{i_\alpha} - x_{i_\beta}) = \delta_{n,L} C_L, \quad n = 1, \ldots, L, \] 

(C21)

where we denote \( H_j^{(\infty)} = \lim_{\eta \to \infty} \eta^{1-L} H_j \). Note that (C20) satisfies (C21), at least for the case \( L = K \) and \( M_j = 1 \) (for all \( 1 \leq j \leq K \)). This fact follows from the following identities:

\[ \sum_{I \subseteq \{1, 2, \ldots, L\}, |I|=n} \prod_{\alpha \in I} \prod_{\beta \in \bar{I}} \frac{1}{x_\alpha - x_\beta} = 0, \quad n = 1, 2, \ldots, L-1. \] 

(C22)

Here we assume that all the \( \{x_i\}_{i=1}^{L} \) are distinct. The case \( L = 2 \) is trivial. Let us take \( L \geq 3 \). One can regard the left hand side of (C22) as a function of \( x_1 \) and denote it as \( f(x_1) \). Apparently, \( f(x_1) \) has a simple pole at \( x_1 = x_i \) for each \( i \in \{2, 3, \ldots, L\} \). However, the residues of \( f(x_1) \) at all these poles vanish. For example, the terms that can contribute to the residue at \( x_1 = x_2 \) (coming from the terms with \( 1 \in I, 2 \in \bar{I} \) or \( 2 \in I, 1 \in \bar{I} \)) have the form

\[ \sum_{J \subseteq \{3, 4, \ldots, L\}, |J|=n-2} \frac{1}{x_1 - x_2} \left\{ \prod_{\beta \in J} (x_1 - x_\beta) \right\} \prod_{\alpha \in J} \frac{1}{x_\alpha - x_2} \prod_{\alpha \in J} \prod_{\beta \in J} (x_\alpha - x_\beta) \]

\[- \prod_{\beta \in J} (x_2 - x_\beta) \prod_{\alpha \in J} (x_\alpha - x_1) \prod_{\alpha \in J} \prod_{\beta \in J} (x_\alpha - x_\beta) \] 

One can easily see that the residue at \( x_1 = x_2 \) is 0. All other cases are considered in a similar way. In addition, \( \lim_{x_1 \to \infty} f(x_1) = 0 \). This proves (C22).
