LIGHT-HADRON ELECTROPRODUCTION AT
NEXT-TO-LEADING ORDER AND IMPLICATIONS

BERND A. KNIEHL

We review recent results on the inclusive electroproduction of light hadrons at
next-to-leading order in the parton model of quantum chromodynamics imple-
mented with fragmentation functions and present updated predictions for HERA
experiments based on the new AKK set. We also discuss phenomenological impli-
cations of these results.

1. Introduction

In the framework of the parton model of quantum chromodynamics (QCD),
the inclusive production of single hadrons is described by means of frag-
mentation functions (FFs) $D_a^h(x, \mu)$. At lowest order (LO), the value of
$D_a^h(x, \mu)$ corresponds to the probability for the parton $a$ produced at short
distance $1/\mu$ to form a jet that includes the hadron $h$ carrying the frac-
tion $x$ of the longitudinal momentum of $a$. Analogously, incoming hadrons
and resolved photons are represented by (non-perturbative) parton density
functions (PDFs) $F_a^h(x, \mu)$. Unfortunately, it is not yet possible to calcu-
late the FFs from first principles, in particular for hadrons with masses
smaller than or comparable to the asymptotic scale parameter $\Lambda$. How-
ever, given their $x$ dependence at some energy scale $\mu$, the evolution with
$\mu$ may be computed perturbatively in QCD using the timelike Dokshitzer-
Gribov-Lipatov-Altarelli-Parisi (DGLAP) equations. Moreover, the factor-
ization theorem guarantees that the $D_a^h(x, \mu)$ functions are independent of
the process in which they have been determined and represent a universal
property of $h$. This entitles us to transfer information on how $a$ hadronizes
to $h$ in a well-defined quantitative way from $e^+e^-$ annihilation, where the
measurements are usually most precise, to other kinds of experiments, such
as photo-, lepto-, and hadroproduction. Recently, FFs for light charged
hadrons with complete quark flavour separation were determined through
a global fit to $e^+e^-$ data from LEP, PEP, and SLC including for the first time the light-quark tagging probabilities measured by the OPAL Collaboration at LEP$^2$ thereby improving previous analyses.$^{3,4}$

The QCD-improved parton model should be particularly well applicable to the inclusive production of light hadrons carrying large transverse momenta ($p_T$) in deep-inelastic lepton-hadron scattering (DIS) with large photon virtuality ($Q^2$) due to the presence of two hard mass scales, with $Q^2, p_T^2 \gg \Lambda^2$. In Fig. 1, this process is represented in the parton-model picture. The hard-scattering (HS) cross sections, which include colored quarks and/or gluons in the initial and final states, are computed in perturbative QCD. They were evaluated at LO more than 25 years ago.$^5$ Recently, the next-to-leading-order (NLO) analysis was performed independently by three groups.$^6,7,8$ A comparison between Refs. 7, 8 using identical input yielded agreement within the numerical accuracy.
The cross section of $e^+p \rightarrow e^+\pi^0 + X$ in DIS was measured in various distributions with high precision by the H1 Collaboration at HERA in the forward region, close to the proton remnant. This measurement reaches down to rather low values of Bjorken’s variable $x_B = Q^2/(2P \cdot q)$, where $P$ and $q$ are the proton and virtual-photon four-momenta, respectively, and $Q^2 = -q^2$, so that the validity of the DGLAP evolution might be challenged by Balitsky-Fadin-Kuraev-Lipatov (BFKL) dynamics.

In Ref. 7, the H1 data were compared with NLO predictions evaluated with the KKP FFs. In Sec. 2, we summarize the analytical calculation performed in Ref. 7. In Sec. 3, we present an update of this comparison based on the new AKK FFs. Our conclusions are summarized in Sec. 4.

2. Analytical calculation

The partonic subprocesses contributing at LO are

$$
\begin{align*}
\gamma^* + q &\rightarrow q + g, \\
\gamma^* + q &\rightarrow g + q, \\
\gamma^* + g &\rightarrow q + \overline{q},
\end{align*}
$$

where $q$ represents any of the $n_f$ active quarks or antiquarks and it is understood that the first of the final-state partons is the one that fragments into the hadron $h$.

At NLO, processes (1) receive virtual corrections, and real corrections arise through the partonic subprocesses

$$
\begin{align*}
\gamma^* + q &\rightarrow q + g + g, \\
\gamma^* + q &\rightarrow g + q + g, \\
\gamma^* + g &\rightarrow q + \overline{q} + g, \\
\gamma^* + g &\rightarrow g + q + \overline{q}, \\
\gamma^* + q &\rightarrow q + q + \overline{q}, \\
\gamma^* + q &\rightarrow \overline{q} + q + q, \\
\gamma^* + q &\rightarrow q + q' + \overline{q}, \\
\gamma^* + q &\rightarrow q' + \overline{q} + q,
\end{align*}
$$

where $q' \neq q, \overline{q}$. The virtual corrections contain infrared (IR) singularities, both of the soft and/or collinear types, and ultraviolet (UV) ones, which are all regularized using dimensional regularization with $D = 4 - 2\epsilon$ space-time dimensions yielding poles in $\epsilon$ in the physical limit $D \rightarrow 4$. The
latter arise from one-loop diagrams and are removed by renormalizing the 
strong-coupling constant and the wave functions of the external partons in 
the respective tree-level diagrams, while the former partly cancel in combi-
nation with the real corrections. The residual IR singularities are absorbed 
into redefinitions of the PDFs and FFs. We extract the IR singularities in 
the real corrections by performing the phase space integrations using the 
dipole subtraction formalism.11

3. Comparison with H1 data

We work in the modified minimal-subtraction (MS) renormalization and 
factorization scheme with \( n_f = 5 \) massless quark flavors and identify the 
renormalization and factorization scales by choosing \( \mu^2 = \xi [Q^2 + (p_T^*)^2]/2 \), 
where the asterisk labels quantities in the \( \gamma^* p \) center-of-mass (c.m.) frame 
and \( \xi \) is varied between 1/2 and 2 about the default value 1 to estimate 
the theoretical uncertainty. At NLO (LO), we employ set CTEQ6M (CTEQ6L1) of proton PDFs,12 
the NLO (LO) set of AKK FFs,1 
and the two-loop (one-loop) formula for the strong-coupling constant \( \alpha_s^{(n_f)}(\mu) \) with 
\( \Lambda(5) = 226 \text{ MeV} \) (165 MeV).12 

The H1 data9,10 were taken in DIS of positrons with energy \( E_e = 27.6 \text{ GeV} \) on protons with energy \( E_p = 820 \text{ GeV} \) in the laboratory frame, 
yielding a c.m. energy of \( \sqrt{S} = 2 \sqrt{E_e E_p} = 301 \text{ GeV} \). The DIS phase 
space was restricted to \( 0.1 < y < 0.6 \) and \( 2 < Q^2 < 70 \text{ GeV}^2 \), where \( y = Q^2/(x_B S) \). The \( \pi^0 \) mesons were detected within the acceptance 
cuts \( p_T^* > 2.5 \text{ GeV} \) (except where otherwise stated), \( 5^\circ < \theta < 25^\circ \), and 
\( x_E > 0.01 \), where \( \theta \) is their angle with respect to the proton flight direction 
and \( E = x_E E_p \) is their energy in the laboratory frame. The comparisons 
with our updated LO and NLO predictions are displayed in Figs. 2(a)–(d). 
The QCD correction (\( K \)) factors, i.e. the NLO to LO cross section ratios, 
are presented in the downmost frame of each figure.

Comparison of Figs. 2(a)–(d) with Figs. 3, 5(a), 6(c), and 7 in Ref. 7, 
where the KKP FFs3 were used, reveals that the update of our FFs, from 
set KKP to set AKK,1 has hardly any visible impact on the theoretical 
predictions considered here. This may be understood by observing that the 
OPAL light-quark tagging probabilities for charged pions,2 included in the 
AKK analysis, agree well with the assumption made in the KKP one that 
\( D_{u,d}^{\pi^\pm}(x, \mu_0) = D_{d,u}^{\pi^\pm}(x, \mu_0) \) at the starting scale \( \mu_0 \) of the DGLAP evolution. 
In Figs. 3(a) and (b),9 the H1 data10 on \( d\sigma/dp_T^* \) for \( 2 < Q^2 < 4.5 \text{ GeV}^2 \), 
\( 4.5 < Q^2 < 15 \text{ GeV}^2 \), or \( 15 < Q^2 < 70 \text{ GeV}^2 \) and on \( d\sigma/dx_B \) for \( p_T^* > 

\( \Lambda(5) = 226 \text{ MeV} \) (165 MeV).12 

The H1 data9,10 were taken in DIS of positrons with energy \( E_e = 27.6 \text{ GeV} \) on protons with energy \( E_p = 820 \text{ GeV} \) in the laboratory frame, 
yielding a c.m. energy of \( \sqrt{S} = 2 \sqrt{E_e E_p} = 301 \text{ GeV} \). The DIS phase 
space was restricted to \( 0.1 < y < 0.6 \) and \( 2 < Q^2 < 70 \text{ GeV}^2 \), where \( y = Q^2/(x_B S) \). The \( \pi^0 \) mesons were detected within the acceptance

\( D_{u,d}^{\pi^\pm}(x, \mu_0) = D_{d,u}^{\pi^\pm}(x, \mu_0) \) at the starting scale \( \mu_0 \) of the DGLAP evolution. 
In Figs. 3(a) and (b),9 the H1 data10 on \( d\sigma/dp_T^* \) for \( 2 < Q^2 < 4.5 \text{ GeV}^2 \), 
\( 4.5 < Q^2 < 15 \text{ GeV}^2 \), or \( 15 < Q^2 < 70 \text{ GeV}^2 \) and on \( d\sigma/dx_B \) for \( p_T^* > 

3.5 GeV and $2 < Q^2 < 8$ GeV$^2$, $8 < Q^2 < 20$ GeV$^2$, or $20 < Q^2 < 70$ GeV$^2$, respectively, are compared with the LO and NLO predictions evaluated with the KKP FFs$^3$ or those by Kretzer (K).$^4$ While the LO predictions based on the KKP and K sets agree very well, the NLO predictions based on the K set appreciably undershoot those based on the KKP set. If it were not for the theoretical uncertainty, one might conclude that the H1 data prefer the KKP set at NLO.

From the downmost frames in Figs. 2(a)–(d), we observe that the $K$ factors are rather sizable, although the $\mu$ values are reasonably large. In Fig. 4,$^8$ the impact of the H1 forward-selection cuts on the $K$ factor is studied for the case of $d\sigma/dx_B$ for $2 < Q^2 < 8$ GeV$^2$ and $p_T^* > 3.5$ GeV. Towards the lower end of the considered $x_B$ range, the $K$ factor reaches one order of magnitude if these cuts are imposed [see also Fig. 2(c)]. However, if the latter are removed, the $K$ factor collapses to acceptable values of around 3. From this finding, we conclude that these cuts almost quench the LO cross section. In other words, in the extreme forward regime, the latter is effectively generated by the $2 \rightarrow 3$ partonic subprocesses of Eq. (2).

It is interesting to investigate the relative importance of the tagged partons, i.e. the one (a) that originates from the proton and the one (b) that fragments into the hadron. In Fig. 5,$^8$ the NLO contributions from the four most important $ab$ channels to $d\sigma/dx_B$ for $2 < Q^2 < 8$ GeV$^2$ and $p_T^* > 3.5$ GeV with the H1 forward-selection cuts are shown together with the total LO contribution. We observe that the $gg$ channel makes up approximately two thirds of the cross section in the low-$x_B$ regime.

4. Conclusions
We calculated the cross section of $ep \rightarrow e\pi^0 + X$ in DIS for finite values of $p_T^*$ at LO and NLO in the parton model of QCD$^7$ using the new AKK FFs$^1$ and compared it with a precise measurement by the H1 Collaboration at HERA.$^9,10$

We found that our LO predictions always significantly fell short of the H1 data and often exhibited deviating shapes. However, the situation dramatically improved as we proceeded to NLO, where our default predictions, endowed with theoretical uncertainties estimated by moderate unphysical-scale variations, led to a satisfactory description of the H1 data in the preponderant part of the accessed phase space. In other words, we encountered $K$ factors much in excess of unity, except towards the regime of asymptotic freedom characterized by large values of $p_T^*$ and/or $Q^2$. This was
unavoidably accompanied by considerable theoretical uncertainties. Both features suggest that a reliable interpretation of the H1 data within the QCD-improved parton model ultimately necessitates a full next-to-next-to-leading-order analysis, which is presently out of reach, however. For the time being, we conclude that the successful comparison of the H1 data with our NLO predictions provides a useful test of the universality and the scaling violations of the FFs, which are guaranteed by the factorization theorem and are ruled by the DGLAP evolution equations, respectively.

Significant deviations between the H1 data and our NLO predictions only occurred in certain corners of phase space, namely in the photoproduction limit $Q^2 \rightarrow 0$, where resolved virtual photons are expected to contribute, and in the limit $\eta \rightarrow \infty$ of the pseudorapidity $\eta = -\ln[\tan(\theta/2)]$, where fracture functions are supposed to enter the stage. Both refinements were not included in our analysis. Interestingly, distinctive deviations could not be observed towards the lowest $x_B$ values probed, which indicates that the realm of BFKL dynamics has not actually been accessed yet.
