Differences between perfect powers: prime power gaps

Michael A. Bennett and Samir Siksek
Differences between perfect powers: prime power gaps

Michael A. Bennett and Samir Siksek

We develop machinery to explicitly determine, in many instances, when the difference $x^2 - y^n$ is divisible only by powers of a given fixed prime. This combines a wide variety of techniques from Diophantine approximation (bounds for linear forms in logarithms, both archimedean and nonarchimedean, lattice basis reduction, methods for solving Thue–Mahler and $S$-unit equations, and the primitive divisor theorem of Bilu, Hanrot and Voutier) and classical algebraic number theory, with results derived from the modularity of Galois representations attached to Frey–Hellegouarch elliptic curves. By way of example, we completely solve the equation

$$x^2 + q^2 = y^n,$$

where $2 \leq q < 100$ is prime, and $x, y, \alpha$ and $n$ are integers with $n \geq 3$ and $\gcd(x, y) = 1$.

1. Introduction

The Lebesgue–Nagell equation

$$x^2 + D = y^n$$

has a very extensive literature, motivated, at least in part, by attempts to extend Mihăilescu’s theorem [2004] (Catalan’s conjecture) to larger gaps in the sequence of perfect powers, in an attempt to attack Pillai’s conjecture [1936]. In (1), we will suppose that $x$ and $y$ are coprime nonzero integers, and that the prime divisors of $D$ belong to a fixed, finite set of primes $S$. Under these assumptions, bounds for linear forms in logarithms, $p$-adic and complex, imply that the set of integer solutions $(x, y, n)$ to (1), with $|y| > 1$ and $n \geq 3$, is finite and effectively determinable. If, in addition, we suppose that $D$ is positive and that $y$ is odd, then these solutions may be explicitly determined, provided $|S|$ is not too large, through appeal to the primitive divisor theorem of Bilu, Hanrot and Voutier [Bilu et al. 2001], in conjunction with techniques from Diophantine approximation.

If either $D > 0$ and $y$ is even, or if $D < 0$, the primitive divisor theorem cannot be applied to solve (1) and we must work rather harder, appealing to either bounds for linear forms in logarithms or to results based upon the modularity of Galois representations associated to certain Frey–Hellegouarch elliptic curves. In a companion paper [Bennett and Siksek 2023], we develop machinery for handling (1) in the first difficult case where $D > 0$ and $y$ is even. Though the techniques we discuss in the present paper are more widely applicable, we will, for simplicity, restrict attention to the case where $D$ in (1) is divisible by a single prime $q$, whilst treating both the cases $D < 0$ and $D > 0$. That is, we will concern ourselves primarily with the equation

$$x^2 + (-1)^\delta q^n = y^n, \quad q \nmid x,$$

where $\delta \in \{0, 1\}$ and $\alpha$ is a nonnegative integer. In the case $\delta = 0$, our main result is the following.

Theorem 1. If $x, y, q, \alpha$ and $n$ are positive integers with $q$ prime, $2 \leq q < 100$, $q \nmid x$, $n \geq 3$ and

$$x^2 + q^n = y^n,$$

then $(q, \alpha, y, n)$ is one of

$$(2, 1, 3, 3), (2, 2, 5, 3), (2, 5, 3, 4), (3, 5, 7, 3), (3, 4, 13, 3), (7, 1, 2, 3), (7, 3, 8, 3), (7, 1, 32, 3), (7, 2, 65, 3), (7, 1, 2, 4), (7, 2, 5, 4), (7, 1, 2, 5), (7, 1, 8, 5), (7, 1, 2, 7), (7, 3, 2, 9), (7, 1, 2, 15), (11, 1, 3, 3), (11, 1, 15, 3), (11, 2, 5, 3), (11, 3, 443, 3), (13, 1, 17, 3), (17, 1, 3, 4), (19, 1, 7, 3), (19, 1, 55, 5), (23, 1, 3, 3), (23, 3, 71, 3), (23, 3, 78, 4), (23, 1, 2, 5), (23, 1, 2, 11), (29, 2, 5, 7), (31, 1, 4, 4), (31, 1, 2, 5), (31, 1, 2, 8), (41, 2, 29, 4), (41, 2, 5, 5), (47, 1, 6, 3), (47, 1, 12, 3), (47, 1, 63, 3), (47, 2, 17, 3), (47, 3, 74, 3), (47, 1, 3, 5), (47, 1, 2, 7), (53, 1, 9, 3), (53, 1, 29, 3), (53, 1, 3, 6), (61, 1, 5, 3), (67, 1, 23, 3), (71, 1, 8, 3), (71, 1, 6, 4), (71, 1, 3, 7), (71, 1, 2, 9), (79, 1, 20, 3), (79, 1, 2, 7), (83, 1, 27, 3), (83, 1, 3, 9), (89, 1, 5, 3), (97, 2, 12545, 3), (97, 1, 7, 4).$$
One might note that the restriction $q \nmid x$ can be removed, with a modicum of effort, at least for certain values of $q$. The cases where primitive divisor arguments are inapplicable correspond to $q \in \{7, 23, 31, 47, 71, 79\}$ and $y$ even (and this is where the great majority of work lies in proving Theorem 1). If $q = 7$, Theorem 1 generalizes recent work of Koutsianas [2020], who established a similar result under certain conditions upon $\alpha$ and $q$, and, in particular, showed that (3) has no solutions with $q = 7$ and prime $n \equiv 13, 23 \pmod{24}$. We note that the solution(s) with $q = 83$ were omitted in the statement of Theorem 1 of Berczes and Pink [2012].

Our results for (2) with $\delta = 1$ are less complete, at least when $\alpha$ is odd.

**Theorem 2.** Suppose that
\[ q \in \{7, 11, 13, 19, 23, 29, 31, 43, 47, 53, 59, 61, 67, 71, 79, 83\}. \]  
If $x$ and $n$ are positive integers, $q \nmid x$, $n \geq 3$ and
\[ x^2 - q^{2k+1} = y^n, \] where $y$ and $k$ are integers, then $(q, k, y, n)$ is one of
\[
(7, 2, 393, 3), \quad (7, 1, -3, 5), \quad (11, 1, 37, 3) \quad (11, 0, 5, 5), \quad (11, 1, 37, 3), \quad (13, 0, 3, 5), \\
(19, 0, 5, 3), \quad (19, 2, -127, 3), \quad (19, 0, -3, 4), \quad (19, 0, 3, 4), \quad (23, 1, 1177, 3), \\
(31, 0, -3, 3), \quad (43, 0, -3, 3), \quad (71, 0, 5, 3), \quad (71, 1, -23, 3), \quad (79, 0, 45, 3). 
\]

To the best of our knowledge, these are the first examples of primes $q$ for which (5) has been completely solved (though the cases with $k = 0$ are treated in the thesis of Barros [2010]). There are eight other primes in the range $3 \leq q < 100$ for which we are unable to give a similarly satisfactory statement. For four of these, namely $q = 3, 5, 17$ and $37$, the equation (5) has a solution with $y = \pm 1$. For such primes we are unaware of any results that would enable us to completely treat fixed exponents $n$ of moderate size; this difficulty is well known for the $D = -2$ case of (1). One should note that it is relatively easy to solve (5) for $q \in \{3, 5, 37\}$, under the additional assumption that $y$ is even (and somewhat harder if $q = 17$ and $y$ is even). For the other four primes, namely $q = 41, 73, 89$ and $97$, we give a method which appears theoretically capable of success, but is alas prohibitively expensive, computationally speaking. We content ourselves by proving the following modest result for these primes.

**Theorem 3.** Let $q \in \{41, 73, 89, 97\}$. The only solutions to (5) with $q \nmid x$ and $3 \leq n \leq 1000$ are with $(q, k, y, n)$ equal to one of
\[
(41, 0, -2, 5), \quad (41, 0, 2, 3), \quad (41, 0, 2, 7), \quad (41, 1, 10, 5), \quad (73, 0, -6, 4), \\
(73, 0, -4, 3), \quad (73, 0, 2, 3), \quad (73, 0, 3, 3), \quad (73, 0, 6, 3), \quad (73, 0, 6, 4), \quad (73, 0, 72, 3), \\
(89, 0, -4, 3), \quad (89, 0, -2, 3), \quad (89, 0, 2, 5), \quad (89, 0, 2, 13), \quad (97, 0, 2, 7). 
\]

There are no solutions to (5) with $n > 1000$, $q \nmid x$ and either $q = 73$ and $y \equiv 0 \pmod{2}$, or with $q = 97$ and $y \equiv 1 \pmod{2}$. 

The additional assumption that the exponent of our prime \( q \) is even simplifies matters considerably. In the case of (3), Berczes and Pink [2008] deduced Theorem 1 for even values of \( \alpha \) (whence primitive divisor technology works efficiently). For completeness, we extend this to \( q < 1000 \); the results for \( q < 100 \) are, of course, just a special case of Theorem 1.

**Theorem 4.** If \( x, y, q, k \) and \( n \) are positive integers with \( q \) prime, \( 2 \leq q < 1000 \), \( q \nmid x \), \( n \geq 3 \) and
\[
x^2 + q^{2k} = y^n,
\]
then \((q, k, y, n)\) is one of
\[
(2, 1, 5, 3), \quad (3, 2, 13, 3), \quad (7, 1, 65, 3), \quad (7, 1, 5, 3), \quad (11, 1, 5, 3), \quad (29, 1, 5, 7), \quad (41, 1, 29, 4), \quad (41, 1, 5, 5), \quad (47, 1, 17, 3), \quad (97, 1, 12545, 3), \quad (107, 1, 37, 3), \quad (191, 1, 65, 3), \quad (239, 1, 169, 4), \quad (239, 1, 13, 8), \quad (431, 1, 145, 3), \quad (587, 1, 197, 3), \quad (971, 1, 325, 3).
\]

More interesting for us is the case where the difference \( x^2 - y^n \) is positive (so that primitive divisor arguments are inapplicable and there are no prior results available in the literature). We prove the following.

**Theorem 5.** If \( x, q, k \) and \( n \) are positive integers with \( q \) prime, \( 2 \leq q < 1000 \), \( q \nmid x \), \( n \geq 3 \) and
\[
x^2 - q^{2k} = y^n,
\]
where \( y \) is an integer, then \((q, k, y, n)\) is one of
\[
(3, 1, -2, 3), \quad (3, 1, 40, 3), \quad (3, 1, \pm 2, 4), \quad (3, 2, -2, 5), \quad (5, 2, 6, 3), \quad (7, 2, 15, 3), \quad (7, 1, 2, 5), \quad (11, 1, 12, 3), \quad (11, 2, 3, 5), \quad (13, 1, 3, 3), \quad (13, 1, 12, 5), \quad (17, 1, -4, 3), \quad (17, 1, \pm 12, 4), \quad (17, 2, 42, 3), \quad (29, 1, -6, 3), \quad (31, 1, 2, 7), \quad (43, 1, -12, 3), \quad (43, 1, 126, 3), \quad (43, 4, 96222, 3), \quad (47, 1, 6300, 3), \quad (53, 1, 6, 3), \quad (71, 1, 30, 3), \quad (71, 2, -136, 3), \quad (89, 1, 84, 3), \quad (97, 2, 3135, 3), \quad (101, 1, 24, 3), \quad (109, 1, 20, 3), \quad (109, 1, 35, 3), \quad (127, 1, -10, 3), \quad (127, 1, 8, 3), \quad (127, 1, 198, 3), \quad (127, 1, 2, 9), \quad (179, 1, -30, 3), \quad (193, 1, 63, 3), \quad (197, 1, 260, 3), \quad (223, 1, 30, 3), \quad (251, 1, -10, 3), \quad (251, 1, -6, 5), \quad (257, 1, -4, 5), \quad (263, 1, 2418, 3), \quad (277, 1, -30, 3), \quad (307, 1, 60, 3), \quad (307, 1, 176, 3), \quad (307, 2, 2262, 3), \quad (359, 1, -28, 3), \quad (383, 2, 25800, 3), \quad (397, 1, -42, 3), \quad (431, 1, 12, 3), \quad (433, 1, -12, 3), \quad (433, 1, 143, 3), \quad (433, 2, 26462, 3), \quad (479, 1, 90, 3), \quad (499, 1, -12, 5), \quad (503, 1, 828, 3), \quad (557, 1, -60, 3), \quad (577, 1, \pm 408, 4), \quad (593, 1, -70, 3), \quad (601, 1, 72, 3), \quad (659, 1, 42, 3), \quad (683, 1, 193346, 3), \quad (701, 1, 4452, 3), \quad (727, 1, 18, 3), \quad (739, 1, 234, 3), \quad (769, 1, 255, 3), \quad (811, 1, -70, 3), \quad (857, 1, -72, 3), \quad (997, 1, 48, 3).
\]

We note that, with sufficient computational power, there is no obstruction to extending the results of Theorems 4 and 5 to larger prime values \( q \). Without fundamentally new ideas, it is not clear that the same may be said of, for example, Theorem 1. In this case, the bounds we obtain upon the exponent \( n \) via linear forms in logarithms, even for relatively small \( q \), leave us with a computation which, while finite, is barely tractable.
Equation (8) has been completely resolved [Ivorra 2003; Siksek 2003] for \( q = 2 \), except for the case \((\alpha, \delta) = (1, 1)\) which corresponds to \( D = -2 \) in (1). The solutions for \( q = 2 \) in our theorems are included for completeness. For the remainder of the paper, we suppose that \( q \) is an odd prime. In particular, we are concerned with the equation
\[
\begin{align*}
  x^2 + (-1)^\delta q^\alpha &= y^n, & \gcd(x, y) = 1, & \alpha > 0,
\end{align*}
\]
where \( q \) is a fixed odd prime, \( n \geq 3 \), and \( \delta \in \{0, 1\} \).

Our proofs will use a broad combination of techniques, which include

- lower bounds for linear forms in complex and \( p \)-adic logarithms which yield bounds for the exponent \( n \) in (8);
- Frey–Hellegouarch curves and their Galois representations which provide a wealth of local information regarding solutions to (8);
- the celebrated primitive divisor theorem of Bilu, Hanrot and Voutier, that can be used to treat most cases of (8) when \( y \) is odd and \( \delta = 0 \);
- elementary descent arguments that reduce (8) for a fixed exponent \( n \) to Thue–Mahler equations, which are possible to resolve thanks to the Thue–Mahler solver associated to [Gherga and Siksek 2022].

The outline of this paper is as follows. In Section 2, we solve the equation \( x^2 + (-1)^\delta q^\alpha = y^n \) for \( n \in \{3, 4\} \) and \( 3 \leq q < 100 \) by reducing the problem to the determination of \( S \)-integral points on elliptic curves. In Section 3, we solve the equation \( x^2 - q^{2k} = y^n \), for \( q \) in the range \( 3 \leq q < 1000 \), with \( y \) odd, using an elementary sieving argument; this completes the proof of Theorem 5 in the case \( y \) is odd. Next, Section 4 provides a short overview of Lucas sequences, their ranks of apparition, and the primitive divisor theorem of Bilu, Hanrot and Voutier. We make use of this machinery in Section 5 to solve the equation \( x^2 + q^{2k} = y^n \) for \( q \) in the range \( 3 \leq q < 1000 \), thereby proving Theorem 4. Section 6 reduces the equation \( x^2 - q^{2k} = y^n \), for even values of \( y \), to Thue–Mahler equations of the form
\[
y^n_1 - 2^{n-2}y^n_2 = q^k.
\]
In Section 7, we give a brief outline of the modular approach to Diophantine equations. Section 8 applies this modular approach, particularly the \((n, n, n)\) Frey–Hellegouarch elliptic curves of Kraus [1997], to (9); this allows us to deduce that there are no solutions for \( 3 \leq q < 1000 \) except for possibly \( q \in \{31, 127, 257\} \), where the mod \( n \) representation of the Frey–Hellegouarch curve arises from that of an elliptic curve with full 2-torsion and conductor \( 2q \). Before we can complete the proof of Theorem 5, we need an upper bound for the exponent \( n \). We give a sharpening of Bugeaud’s bound [1997] for the equation \( x^2 - q^{2k} = y^n \), which uses (9) and the theory of linear forms in real and \( p \)-adic logarithms. In Section 10, we complete the proof of Theorem 5; our approach makes use of a sieving technique that builds on the information obtained from the modular approach in Section 8 and the upper bound for \( n \) established in Section 9. The remainder of the paper is concerned with (8) where \( \alpha = 2k + 1 \), and for \( 3 \leq q < 100 \). In Section 11, we
solve $x^2 + q^{2k+1} = y^n$ with $y$ odd with the help of the primitive divisor theorem, and in Section 12 we solve $x^2 - q^{2k+1} = y^5$ by reducing to Thue–Mahler equations.

It remains, then, to handle the equations $x^2 - q^{2k+1} = y^n$ and $x^2 + q^{2k+1} = y^n$ where, in the latter case, we may additionally assume that $y$ is even. In Section 13, we study the more general equation

$$y^n + q^\alpha z^n = x^2, \quad \gcd(x, y) = 1,$$

where $q$ is prime, using Galois representations of Frey–Hellegouarch curves. Our approach builds on previous work of Bennett and Skinner [2004], and also on the work of Ivorra and Kraus [2006]. We then restrict ourselves in Section 14 to the case $z = \pm 1$ and $\alpha$ odd in (10). In this section, we develop a variety of sieves based upon local information coming from the Frey–Hellegouarch curves that allows us, in many situations, to eliminate values of $q$ from consideration completely and, in the more difficult cases, to solve (8) for a fixed pair $(q, n)$. In particular, we employ this strategy to complete the proofs of Theorems 2 and 3. Finally, in Section 15, we return to bounds for linear forms in $p$-adic and complex logarithms to derive explicit upper bounds upon $n$ in (8), and then report upon a (somewhat substantial) computation to use the arguments of Section 14 to solve (8) for all remaining pairs $(q, n)$ required to finish the proof of Theorem 1.

2. Reduction to $S$-integral points on elliptic curves for $n \in \{3, 4\}$

In the following sections, it will be of value to us to assume that the exponent $n$ in (8) is not too small. This is primarily to ensure that the Frey–Hellegouarch curve we attach to a putative solution has a corresponding mod $n$ Galois representation that is irreducible. For suitably large prime values of $n$ (typically, $n \geq 7$), the desired irreducibility follows from Mazur’s isogeny theorem. In Section 4, such an assumption allows us to (mostly) ignore so-called defective Lucas sequences.

In this section, we treat separately the cases $n = 3$ and $n = 4$ for $q < 100$, where the problem of solving (8) reduces immediately to one of determining $S$-integral points on specific models of genus one curves; here $S = \{q\}$. This approach falts for many values of $q$ in the range $100 < q < 1000$ as we are often unable to compute the Mordell–Weil groups of the relevant elliptic curves. Thus for the proofs of Theorems 4 and 5 for exponents $n = 3, n = 4$, where we treat values of $q$ less than 1000, we shall employ different techniques including sieving arguments and reduction to Thue–Mahler equations.

The case $n = 3$. Supposing that we have a coprime solution to (8) with $n = 3$, we can write $\alpha = 6b + c$, where $0 \leq c \leq 5$. Taking $X = y/q^{2b}$ and $Y = x/q^{3b}$, it follows that $(X, Y)$ is an $S$-integral point on the elliptic curve

$$Y^2 = X^3 + (-1)^{\delta+1} q^c,$$

where $S = \{q\}$. Here, for a particular choice of $\delta \in \{0, 1\}$ and prime $q$ we may use the standard method for computing $S$-integral points on elliptic curves based on lower bounds for linear forms in elliptic logarithms (e.g., [Pethő et al. 1999]). We made use of the built-in Magma [Bosma et al. 1997] implementation of this
The case $n = 4$. Next we consider the case $n = 4$ separately. Write $\alpha = 4b + c$ where $0 \leq c \leq 3$. Let $X = (y/q^b)^2, Y = xy/q^{3b}$. Then $(X, Y)$ is an $S$-integral point on the elliptic curve

$$Y^2 = X(X^2 + (-1)^{\delta+1}q^\gamma),$$

(12)
Table 2. Solutions to the equation $x^2 + (-1)^\delta q^\alpha = y^4$ for primes $2 \leq q < 100$, $\delta \in \{0, 1\}$ and $x, y, \alpha$ integers satisfying $\alpha > 0$, $x > 0$, $y > 0$, and $\gcd(x, y) = 1$.

where $S = \{q\}$. We again appealed to the built-in Magma [Bosma et al. 1997] implementation of this method to compute these $S$-integral points on (12) for $\delta \in \{0, 1\}$ and $2 \leq q < 100$. We obtained a total of 16 solutions to (8) for these values of $q$ with $\alpha > 0$, $x > 0$, $y > 0$ and $\gcd(x, y) = 1$. These are given in Table 2.

3. An elementary approach to $x^2 − q^{2k} = y^n$ with $y$ odd

In this section, we apply an elementary factorization argument to prove Theorem 5 for $y$ odd. In other words, we consider the equation

$$x^2 − q^{2k} = y^n, \quad x, k, n \text{ positive integers, } n \geq 3, \gcd(x, y) = 1, \ y \text{ an odd integer.}$$

(13)

Here $q \geq 3$ is a prime. From this, we immediately see that

$$x + q^k = y_1^n \quad \text{and} \quad x − q^k = y_2^n,$$

(14)

with $y = y_1 y_2$, so that we have

$$y_1^n − y_2^n = 2q^k.$$

(15)

If $2 \mid n$, then $y_1^n \equiv y_2^n \equiv 1 \pmod{4}$, a contradiction. We may suppose henceforth, without loss of generality, that $n$ is an odd prime. Observe that

$$(y_1 − y_2)(y_1^{n−1} + y_1^{n−2}y_2 + \cdots + y_2^{n−1}) = y_1^n − y_2^n = 2q^k.$$  

(16)

Clearly $y_1 > y_2$ and, as they are both odd, $y_1 − y_2 \geq 2$ and $2 \mid (y_1 − y_2)$. Write

$$d = \gcd(y_1 − y_2, y_1^{n−1} + y_1^{n−2}y_2 + \cdots + y_2^{n−1})$$

so that $y_2 \equiv y_1 \pmod{d}$ and

$$0 \equiv y_1^{n−1} + y_1^{n−2}y_2 + \cdots + y_2^{n−1} \equiv ny_1^{n−1} \pmod{d}.$$  

Similarly, we have $ny_2^{n−1} \equiv 0 \pmod{d}$ and so $d \in \{1, n\}$.
We first deal with the case \( d = n \), whereby, from (16), \( q = n \). Let \( r = \text{ord}_n(y_1 - y_2) \geq 1 \) and write \( y_1 = y_2 + n'\kappa \) where \( n \nmid \kappa \). Then
\[
\text{ord}_n\left(y_1^{n-1} + y_1^{n-2}y_2 + \ldots + y_2^{n-1}\right) = \text{ord}_n\left(\frac{(y_2 + n'\kappa)^n - y_2^n}{n'\kappa}\right) = 1.
\]
Hence
\[
y_1 - y_2 = 2n^{k-1} \quad \text{and} \quad y_1^{n-1} + y_1^{n-2}y_2 + \ldots + y_2^{n-1} = n,
\]
and so
\[
n = \prod_{i=1}^{n-1} |y_1 - \zeta_n^i y_2| \geq |y_1| - |y_2|^{n-1}.
\]
Recall that \( y_1 \) and \( y_2 \) are both odd. If \( y_2 \neq \pm y_1 \), then the right-hand side of this last inequality is at least \( 2^{n-1} \), which is impossible. Thus \( y_2 = \pm y_1 \), so that, from (17), \( y_1^{n-1} | n \). It follows that \( |y_1| = |y_2| = 1 \), contradicting (14).

Thus \( d = 1 \), whence
\[
y_1 - y_2 = 2 \quad \text{and} \quad y_1^{n-1} + y_1^{n-2}y_2 + \ldots + y_2^{n-1} = q^k.
\]
Since the polynomial \( X^{n-1} + X^{n-2} + \ldots + 1 \) has a root modulo \( q \), the Dedekind–Kummer theorem tells us that \( q \) splits in \( \mathbb{Z}[\zeta_n] \) and so \( q \equiv 1 \pmod{n} \). We therefore have the following.

**Proposition 3.1.** If \( x, y, q, k \) and \( n \) are positive integers satisfying (13) with \( n \) and \( q \) prime, then \( n \mid (q-1) \) and there exists an odd positive integer \( X \) such that \( y = X(X + 2) \) and
\[
(X + 2)^n - X^n = 2q^k.
\]

This last result makes it an extremely straightforward matter to solve (7) in the case \( y \) is odd.

**Lemma 3.2.** The only solutions to (13) with \( 3 \leq q < 1000 \) prime correspond to the identities
\[
76^2 - 7^4 = 15^3, \quad 122^2 - 11^4 = 35, \quad 14^2 - 13^2 = 3^3, \quad 175784^2 - 97^4 = 3135^3, \\
234^2 - 109^2 = 35^3, \quad 536^2 - 193^2 = 63^3, \quad 1764^2 - 433^2 = 143^3, \quad 4144^2 - 769^2 = 255^3.
\]

**Proof.** Suppose first that \( n = 3 \), where (19) becomes
\[
3(X + 1)^2 + 1 = q^k.
\]
From [Cohn 1997; 2003], we know that the equation \( 3u^2 + 1 = y^m \) has no solutions with \( m \geq 3 \). We conclude that \( k = 1 \) or \( 2 \). Solving (20) with \( k = 1 \) or \( 2 \) and \( 3 \leq q < 1000 \) leads to the seven solutions with \( n = 3 \).

We now suppose that \( n \geq 5 \) is prime. By a theorem of Bennett and Skinner [2004, Theorem 2], the only solutions to the equation \( X^n + Y^n = 2Z^2 \) with \( n \geq 5 \) prime and \( \gcd(X, Y) = 1 \) are with either \( |XY| = 1 \) or \( (n, X, Y, Z) = (5, 3, -1, \pm 11) \). We note that if \( k \) is even then (19) can be rewritten as \( (X + 2)^n - X^n = 2(q^{k/2})^2 \), and therefore \( n = 5, X = 1 \) and \( q^{k/2} = 11 \). This yields the solution \( 122^2 - 11^4 = 3^5 \).
We may therefore suppose that \( k \) is odd. Recalling that \( n \mid (q - 1) \) leaves us with precisely 191 pairs \((q, n)\) to consider, ranging from \((11, 5)\) to \((997, 83)\). Fix one of these pairs \((q, n)\) and let \( \ell \mid nq \) be an odd prime. Let \( \mathcal{Z}_\ell \) be the set of \( \beta \in \mathbb{Z}/(\ell - 1)\mathbb{Z} \) such that \( \beta \) is odd and the polynomial
\[
(X + 2)^n - X^n - 2q^\beta
\]
has a root in \( \mathbb{F}_\ell \). We note that the value of \( q^k \) modulo \( \ell \) depends only on the residue class of \( k \) modulo \( \ell - 1 \). From (19), we deduce that \( (k \mod \ell) \in \mathcal{Z}_\ell \). Now let \( \ell_1, \ell_2, \ldots, \ell_m \) be a collection of odd primes with \( \ell_i \not\mid nq \) for \( 1 \leq i \leq m \). Let
\[
M = \text{lcm}(\ell_1 - 1, \ell_2 - 1, \ldots, \ell_m - 1)
\]
and set
\[
\mathcal{Z}_{\ell_1, \ldots, \ell_m} = \{ \beta \in \mathbb{Z}/M\mathbb{Z} : (\beta \mod \ell_i) \in \mathcal{Z}_{\ell_i} \text{ for } i = 1, \ldots, m \}.
\]
It is clear that \( (k \mod M) \in \mathcal{Z}_{\ell_1, \ldots, \ell_m} \). We wrote a short \texttt{Magma} script which, for each pair \((q, n)\), computed \( \mathcal{Z}_{\ell_1, \ldots, \ell_m} \) where \( \ell_1, \ell_2, \ldots, \ell_m \) are the odd primes \( \leq 101 \) distinct from \( n \) and \( q \). In all 191 cases we found that \( \mathcal{Z}_{\ell_1, \ldots, \ell_m} = \emptyset \), completing the desired contradiction. \( \square \)

4. Lucas sequences and the primitive divisor theorem

The primitive divisor theorem of Bilu, Hanrot and Voutier [Bilu et al. 2001] shall be our main tool for treating (8) when \( \delta = 0 \) and \( y \) is odd. In this section, we state this result and a related theorem of Carmichael that shall be useful later. A pair of algebraic integers \((\gamma, \delta)\) is called a Lucas pair if \( \gamma + \delta \) and \( \gamma \delta \) are nonzero coprime rational integers, and \( \gamma/\delta \) is not a root of unity. We say that two Lucas pairs \((\gamma_1, \delta_1)\) and \((\gamma_2, \delta_2)\) are equivalent if \( \gamma_1/\gamma_2 = \pm 1 \) and \( \delta_1/\delta_2 = \pm 1 \). Given a Lucas pair \((\gamma, \delta)\) we define the corresponding Lucas sequence by
\[
L_m = \frac{\gamma^m - \delta^m}{\gamma - \delta}, \quad m = 0, 1, 2, \ldots
\]
A prime \( \ell \) is said to be a primitive divisor of the \( m \)-th term if \( \ell \) divides \( L_m \) but \( \ell \) does not divide \( (\gamma - \delta)^2 \cdot L_1 L_2 \cdots L_{m-1} \).

**Theorem 6** [Bilu et al. 2001]. Let \((\gamma, \delta)\) be a Lucas pair and write \( \{L_m\} \) for the corresponding Lucas sequence.

(i) If \( m \geq 30 \), then \( L_m \) has a primitive divisor.

(ii) If \( m \geq 11 \) is prime, then \( L_m \) has a primitive divisor.

(iii) \( L_7 \) has a primitive divisor unless \((\gamma, \delta)\) is equivalent to \((a - \sqrt{b})/2, (a + \sqrt{b})/2\) where
\[
(a, b) \in \{(1, -7), (1, -19)\}.
\]

(iv) \( L_5 \) has a primitive divisor unless \((\gamma, \delta)\) is equivalent to \((a - \sqrt{b})/2, (a + \sqrt{b})/2\) where
\[
(a, b) \in \{(1, 5), (1, -7), (2, -40), (1, -11), (1, -15), (12, -76), (12, -1364)\}.
\]
Let \( \ell \) be a prime. We define the \textit{rank of apparition} of \( \ell \) in the Lucas sequence \( \{L_m\} \) to be the smallest positive integer \( m \) such that \( \ell \mid L_m \). We denote the rank of apparition of \( \ell \) by \( m_\ell \). The following theorem will be useful for us; a concise proof may be found in [Bennett et al. 2022, Theorem 8].

**Theorem 7** [Carmichael 1913]. Let \( (\gamma, \delta) \) be a Lucas pair, and \( \{L_m\} \) the corresponding Lucas sequence. Let \( \ell \) be a prime.

(i) If \( \ell \mid \gamma \delta \) then \( \ell \nmid L_m \) for all positive integers \( m \).

(ii) Suppose \( \ell \nmid \gamma \delta \). Write \( D = (\gamma - \delta)^2 \in \mathbb{Z} \).

(a) If \( \ell \neq 2 \) and \( \ell \mid D \), then \( m_\ell = \ell \).

(b) If \( \ell \neq 2 \) and \( \left( \frac{D}{\ell} \right) = 1 \), then \( m_\ell \mid (\ell - 1) \).

(c) If \( \ell \neq 2 \) and \( \left( \frac{D}{\ell} \right) = -1 \), then \( m_\ell \mid (\ell + 1) \).

(d) If \( \ell = 2 \), then \( m_\ell = 2 \) or \( 3 \).

(iii) If \( \ell \nmid \gamma \delta \) then

\[
\ell \mid L_m \iff m_\ell \mid m.
\]

5. The equation \( x^2 + q^{2k} = y^n \): the proof of Theorem 4

In this section, we prove Theorem 4 with the help of the primitive divisor theorem. We are concerned with the equation

\[
x^2 + q^{2k} = y^n, \quad x, k, n \text{ positive integers, } n \geq 3, \gcd(x, y) = 1.
\] (25)

Here \( q \geq 3 \) is a prime. Considering this equation modulo 8 immediately tells us that \( y \) is odd and \( x \) is even. Without loss of generality, we may suppose that \( 4 \mid n \) or that \( n \) is divisible by an odd prime.

**Lemma 5.1.** Solutions to (25) with \( 4 \mid n \) and odd prime \( q \) satisfy \( k = 1 \), \( q^2 = 2y^{n/2} - 1 \) and \( x = (q^2 - 1)/2 \). In particular, the only solutions to (25) with \( 4 \mid n \) and prime \( 3 \leq q < 1000 \) correspond to the identities

\[
24^2 + 7^2 = 5^4, \quad 840^2 + 41^2 = 29^4 \quad \text{and} \quad 28560^2 + 239^2 = 13^8 = 169^4.
\]

**Proof.** Suppose that \( 4 \mid n \). Then \( (y^{n/2} + x)(y^{n/2} - x) = q^{2k} \), and so

\[
y^{n/2} + x = q^{2k} \quad \text{and} \quad y^{n/2} - x = 1.
\]

Thus \( 2y^{n/2} = q^{2k} + 1 \). By Theorem 1 of [Bennett and Skinner 2004], the only solutions to the equation \( A^r + B^r = 2C^2 \) with \( r \geq 4 \), \( ABC \neq 0 \) and \( \gcd(A, B) = 1 \) are with \( |AB| = 1 \) or \( (r, A, B, C) = (5, 3, -1, \pm 11) \). It follows that the equation \( 2y^{n/2} = q^{2k} + 1 \) has no solutions with \( k \geq 2 \) and \( 4 \mid n \). Therefore \( k = 1 \), and hence \( q^2 = 2y^{n/2} - 1 \). The only primes in the range \( 3 \leq q < 1000 \), such that \( q^2 = 2y^{n/2} - 1 \) with \( 4 \mid n \), are \( q = 7, 41 \) and \( 239 \), which lead to the solutions stated in the lemma. \( \square \)
Henceforth, we will suppose that \( n \) is an odd prime. Thus \( x + q^k i = \alpha^n \), where we can write \( \alpha = a + bi \), for \( a \) and \( b \) coprime integers with \( y = a^2 + b^2 \). Subtracting this equation from its conjugate yields
\[
q^k = b \cdot \frac{\alpha^n - \overline{\alpha}^n}{\alpha - \overline{\alpha}}.
\]

Lemma 5.2. Solutions to (25) with \( n = 3 \) and odd prime \( q \) must satisfy

(i) either \( q = 3 \) and \( (k, x, y) = (2, 46, 13) \);
(ii) or \( q = 3a^2 - 1 \) for some positive integer \( a \) and \( (k, x, y) = (1, a^3 - 3a, a^2 + 1) \);
(iii) or \( q^2 = 3a^2 + 1 \) for some positive integer \( a \) and \( (k, x, y) = (1, 8a^3 + 3a, 4a^2 + 1) \).

In particular, the only solutions to (25) with \( n = 3 \) and prime \( 3 \leq q < 1000 \) correspond to the identities
\[
46^2 + 3^4 = 13^3, \quad 524^2 + 7^2 = 65^3, \quad 2^2 + 11^2 = 5^3, \quad 52^2 + 47^2 = 17^3, \\
1405096^2 + 97^2 = 12545^3, \quad 198^2 + 107^2 = 37^3, \quad 488^2 + 191^2 = 65^3, \\
1692^2 + 431^2 = 145^3, \quad 2702^2 + 587^2 = 197^3, \quad 5778^2 + 971^2 = 325^3.
\]

Proof. Let \( n = 3 \). Thanks to Table 1, we know that the only solution with \( q = 3 \) is the one given in (i). We may thus suppose that \( q \geq 5 \). Equation (26) gives
\[
q^k = b(3a^2 - b^2).
\]
By the coprimality of \( a \) and \( b \), we have \( b = \pm 1 \) or \( b = \pm q^k \). We note that \( b = -1 \) gives \( q^k = 1 - 3a^2 \) which is impossible. Also if \( b = q^k \) then \( 3a^2 - q^{2k} = 1 \) which is impossible modulo 3. Thus either \( b = 1 \) or \( b = -q^k \). If \( b = 1 \), then
\[
q^k = 3a^2 - 1,
\]
and if \( b = -q^k \) then
\[
q^{2k} = 3a^2 + 1.
\]
From Theorem 1.1 of [Bennett and Skinner 2004], these equations have no solutions in positive integers if \( k \geq 4 \) or \( k \geq 2 \), respectively. If \( k = 3 \), the elliptic curve corresponding to the first equation has Mordell–Weil rank 0 over \( \mathbb{Q} \) and it is straightforward to show that the equation has no integer solutions. We therefore have that \( k = 1 \) in either case. Thus \( q = 3a^2 - 1 \) or \( q^2 = 3a^2 + 1 \), and these yield the parametric solutions in (ii) and (iii). For \( 5 \leq q < 1000 \), the primes \( q \) of the form \( 3a^2 - 1 \) are
\[
11, 47, 107, 191, 431, 587, 971.
\]
For \( 5 \leq q < 1000 \), the primes \( q \) satisfying \( q^2 = 3a^2 + 1 \) are \( q = 7 \) and 97. These yield the solutions given in the statement of the lemma.

We expect that there are infinitely many primes \( q \) of the form \( 3a^2 - 1 \), but are very unsure about the number of primes \( q \) satisfying \( q^2 = 3a^2 + 1 \) (the only ones known are 7, 97 and 708158977). Quantifying such results, in any case, is well beyond current technology.
In view of Lemma 5.2, we henceforth suppose that \( n \geq 5 \) and prime. The following lemma now completes the proof of Theorem 4.

**Lemma 5.3.** Let \((k, x, y, n)\) be a solution to (25) with prime \( n \geq 5 \) and odd prime \( q \). Then \( k \) is odd,

\[
\begin{cases}
  n \mid (q - 1) & \text{if } q \equiv 1 \pmod{4}, \\
  n \mid (q + 1) & \text{if } q \equiv 3 \pmod{4},
\end{cases}
\quad (27)
\]

and there is an integer \( a \) such that

\[
y = a^2 + 1, \quad x = \frac{(a + i)^n + (a - i)^2}{2}, \quad \frac{(a + i)^n - (a - i)^n}{2i} = \pm q^k.
\]

In particular, the only solutions to (25) with prime \( 3 \leq q < 1000 \) and prime \( n \geq 5 \) correspond to the identities

\[
38^2 + 41^2 = 5^5, \quad 278^2 + 29^2 = 5^7.
\]

**Proof.** Suppose \( n \geq 5 \) and prime in (25). By Theorem 1 of [Bennett et al. 2010], the equation \( A^4 + B^2 = C^m \) has no solutions satisfying \( \gcd(A, B) = 1, AB \neq 0 \) and \( m \geq 4 \). We conclude that \( k \) is odd. We note that \((\alpha, \overline{\alpha})\) is a Lucas pair and write \([L_m]\) for the corresponding Lucas sequence. By Theorem 6, \( L_n \) must have a primitive divisor, and from (26) this primitive divisor is \( q \). In particular, \( q \) does not divide \( D = (\alpha - \overline{\alpha})^2 = -4\beta^2 \). Thus by (26) we have \( b = \pm 1 \) and \( D = -4 \). Moreover, the rank of apparition of \( q \) in the sequence is \( n \). By Theorem 7, we have \( n \mid (q - 1) \) if \( q \equiv 1 \pmod{4} \) and \( n \mid (q + 1) \) if \( q \equiv 3 \pmod{4} \).

We now let \( q \) be a prime in the range \( 3 \leq q < 1000 \). There are 168 pairs \((q, n)\) with \( q \) in this range and \( n \) a prime \( \geq 5 \) satisfying (27), ranging from \((19, 5)\) to \((997, 83)\). For each of these pairs \((q, n)\), and each sign \( \eta = \pm 1 \), we need to consider the equation

\[
\frac{(a + i)^n - (a - i)^n}{2i} = \eta \cdot q^k,
\]

where \( k \) is an odd integer. We shall follow the sieving approach of Lemma 3.2 to eliminate all but two of the possible \( 2 \times 168 = 336 \) triples \((q, n, \eta)\). Fix such a triple \((q, n, \eta)\). Let \( f_n \in \mathbb{Z}[X] \) be the polynomial

\[
f_n(X) = \frac{(X + i)^n - (X - i)^n}{2i}.
\]

Let \( \ell \mid nq \) be an odd prime, and let \( \mathcal{Z}_\ell \) be the set \( \beta \in \mathbb{Z}/(\ell - 1)\mathbb{Z} \) such that \( \beta \) is odd and \( f_n(X) - \eta \cdot q^\beta \) has a root in \( \mathbb{F}_\ell \). It follows that \((k \pmod{\ell}) \in \mathcal{Z}_\ell \). Now let \( \ell_1, \ell_2, \ldots, \ell_m \) be a collection of odd primes \( \nmid qn \). Define \( M \) and \( \mathcal{Z}_{\ell_1, \ldots, \ell_m} \) by (21) and (22), respectively. It is clear that \((k \pmod{M}) \in \mathcal{Z}_{\ell_1, \ldots, \ell_m} \). We wrote a short Magma script which, for each triple \((q, n, \eta)\), computed \( \mathcal{Z}_{\ell_1, \ldots, \ell_m} \) where \( \ell_1, \ldots, \ell_m \) are the odd primes \( < 150 \) distinct from \( n \) and \( q \). In all but two of the 336 cases we found that \( \mathcal{Z}_{\ell_1, \ldots, \ell_m} = \emptyset \). The two exceptions are \((q, n, \eta) = (41, 5, 1)\) and \((29, 7, -1)\), and so these are the only two cases we need to consider. Let

\[
F_n(X, Y) = \frac{(X + iY)^n - (X - iY)^n}{2iY}.
\]
This is a homogeneous degree \( n - 1 \) polynomial belonging to \( \mathbb{Z}[X, Y] \). Now (28) can be written as \( F_n(a, 1) = \eta \cdot q^k \). Thus it is sufficient to solve the Thue–Mahler equations \( F_n(X, Y) = \eta \cdot q^k \) for \((q, n, \eta) = (41, 5, 1)\) and \((29, 7, -1)\). Explicitly these equations are
\[
5X^4 - 10X^2Y^2 + Y^4 = 41^k
\]
and
\[
7X^6 - 35X^4Y^2 + 21X^2Y^4 - Y^6 = -29^k.
\]
Using the Magma implementation of the Thue–Mahler solver described in [Gherga and Siksek 2022], we find that the solutions to (29) are \((X, Y, k) = (\pm 2, \pm 1, 1)\) and \((0, \pm 1, 0)\), and that the solutions to (30) are also \((X, Y, k) = (\pm 2, \pm 1, 1)\) and \((0, \pm 1, 0)\). These lead to the two solutions stated in the lemma. \( \square \)

6. The equation \( x^2 - q^{2k} = y^n \) with \( y \) even: reduction to Thue–Mahler equations

Section 3 dealt with (7) in the case that \( y \) is odd, using purely elementary means. We now turn our attention to (7) with \( y \) even, and consider the equation
\[
x^2 - q^{2k} = y^n, \quad x, k, n \text{ positive integers, } n \geq 3, \gcd(x, y) = 1, \ y \text{ an even integer.} \quad (31)
\]
Here \( q \geq 3 \) is a prime and, without loss of generality, \( n = 4 \) or \( n \) is an odd prime.

**Lemma 6.1.** Write \( \gamma = 1 + \sqrt{2} \). Any solution to (31) with \( n = 4 \) and \( q \) an odd prime must satisfy \( k = 1 \),
\[
q = \frac{\gamma^{2m} + \gamma^{-2m}}{2}, \quad x = \frac{\gamma^{4m} + \gamma^{-4m}}{8} \text{ and } \ y = \frac{\gamma^{2m} - \gamma^{-2m}}{2\sqrt{2}},
\]
for some integer \( m \). In particular, the only solutions with \( 3 \leq q < 1000 \) correspond to the identities
\[
5^2 - 3^2 = (\pm 2)^4, \quad 145^2 - 17^2 = (\pm 12)^4 \quad \text{and} \quad 166465^2 - 577^2 = (\pm 408)^4.
\]

**Proof.** Suppose \( n = 4 \). Then \((x + y^2)(x - y^2) = q^{2k}\), and so, by the coprimality of \( x \) and \( y \),
\[
x + y^2 = q^{2k} \quad \text{and} \quad x - y^2 = 1,
\]
or equivalently
\[
x = \frac{q^{2k} + 1}{2} \quad \text{and} \quad q^{2k} - 2y^2 = 1. \quad (33)
\]
First we show that \( k = 1 \). From the second equation, we have \((q^k + 1)(q^k - 1) = 2y^2\). Since the greatest common divisor of the two factors on the left is 2 we see that one of the two factors must be a perfect square, i.e., \( q^k + 1 = z^2 \) or \( q^k - 1 = z^2 \) for some nonzero integer \( z \), and it is easy to see that \( k \) must be odd. The impossibility of these cases for \( k \geq 3 \) follows from Mihăilescu’s theorem [2004] (Catalan’s conjecture). Hence \( k = 1 \).

The second equation in (33) implies that \( q + y\sqrt{2} \) is a totally positive unit in \( \mathbb{Z}[\sqrt{2}] \). Thus
\[
q + y\sqrt{2} = \gamma^{2m} \quad \text{and} \quad q - y\sqrt{2} = \gamma^{-2m}, \quad (34)
\]
for some integer $m$. The formulae for $q$ and $y$ in (32) follow from this, and the formula for $x$ follows from the first relation in (33).

We focus on primes $3 \leq q < 1000$. From the first relation in (34),
\[ |m| < \frac{\log(2q)}{2\log \gamma} < \frac{\log 2000}{2\log(1 + \sqrt{2})} < 5. \]
Thus $-4 \leq m \leq 4$. The values $m = \pm 1, \pm 2, \pm 4$, respectively, give the three solutions in the statement of the lemma. If $m = 0$ or $\pm 3$, then we obtain $q = 1$ or $99$ which are not prime.

In view of Lemma 6.1, we may henceforth suppose that $n \geq 3$ is odd. Let $x'$ be either $x$ or $-x$, chosen so that $x' \equiv q^k \pmod{4}$. From (31), we deduce the existence of relatively prime integers $y_1$ and $y_2$ for which
\[ x' + q^k = 2y_1^n \quad \text{and} \quad x' - q^k = 2^{n-1}y_2^n, \tag{35} \]
with $y = 2y_1y_2$, so that we have
\[ y_1^n - 2^{n-2}y_2^n = q^k. \tag{36} \]
We have thus reduced the resolution of (31) for particular $q$ and $n$ to solving a degree $n$ Thue–Mahler equation.

**Lemma 6.2.** The only solutions to (31) with $n \in \{3, 5\}$ and $3 \leq q < 1000$ an odd prime correspond to the identities
\[
\begin{align*}
53^2 - 3^2 &= 40^3, \\
1^2 - 3^2 &= (-2)^3, \\
7^2 - 3^4 &= (-2)^5, \\
29^2 - 5^4 &= 6^3, \\
9^2 - 7^2 &= 2^5, \\
43^2 - 11^2 &= 12^3, \\
499^2 - 13^2 &= 12^5, \\
15^2 - 17^2 &= -4^3, \\
397^2 - 17^4 &= 42^3, \\
25^2 - 29^2 &= (-6)^3, \\
11^2 - 43^2 &= (-12)^3, \\
1415^2 - 43^2 &= 126^3, \\
30042907^2 - 43^8 &= 96222^3, \\
500047^2 - 47^2 &= 6300^3, \\
55^2 - 53^2 &= 6^3, \\
179^2 - 71^2 &= 30^3, \\
4785^2 - 71^4 &= (-136)^3, \\
775^2 - 89^2 &= 84^3, \\
155^2 - 101^2 &= 24^3, \\
13609^2 - 109^2 &= 570^3, \\
141^2 - 109^2 &= 20^3, \\
129^2 - 127^2 &= 8^3, \\
123^2 - 127^2 &= (-10)^3, \\
2789^2 - 127^2 &= 198^3, \\
71^2 - 179^2 &= (-30)^3, \\
4197^2 - 197^2 &= 260^3, \\
277^2 - 223^2 &= 30^3, \\
249^2 - 251^2 &= (-10)^3, \\
235^2 - 251^2 &= (-6)^5, \\
255^2 - 257^2 &= -4^5, \\
118901^2 - 263^2 &= 2418^3, \\
223^2 - 277^2 &= (-30)^3, \\
2355^2 - 307^2 &= 176^3, \\
143027^2 - 307^4 &= 2262^3, \\
557^2 - 307^2 &= 60^3, \\
327^2 - 359^2 &= (-28)^3, \\
4146689^2 - 383^2 &= 25800^3, \\
289^2 - 397^2 &= (-42)^3, \\
433^2 - 431^2 &= 12^3, \\
431^2 - 433^2 &= (-12)^3, \\
4308693^2 - 433^4 &= 26462^3, \\
979^2 - 479^2 &= 90^3, \\
13^2 - 499^2 &= (-12)^5, \\
23831^2 - 503^2 &= 828^3, \\
307^2 - 557^2 &= (-60)^3, \\
93^2 - 593^2 &= (-70)^3, \\
857^2 - 601^2 &= 72^3, \\
713^2 - 659^2 &= 42^3, \\
85016415^2 - 683^2 &= 193346^3, \\
297053^2 - 701^2 &= 4452^3, \\
731^2 - 727^2 &= 18^3, \\
3655^2 - 739^2 &= 234^3, \\
561^2 - 811^2 &= (-70)^3, \\
601^2 - 857^2 &= (-72)^3, \\
1051^2 - 997^2 &= 48^3. 
\end{align*}
\]

**Proof.** For $n \in \{3, 5\}$ and primes $3 \leq q < 1000$, we solved the Thue–Mahler equation (36) using the Magma implementation of the Thue–Mahler solver described in [Ghera and Siksek 2022]. The computation resulted in the solutions given in the statement of the lemma. \qed
7. The modular approach to Diophantine equations: some background

Let $F/\mathbb{Q}$ be an elliptic curve over the rationals of conductor $N_F$ and minimal discriminant $\Delta_F$. Let $p \geq 5$ be a prime. The action of $\text{Gal}((\overline{\mathbb{Q}})/\mathbb{Q})$ on the $p$-torsion $F[p]$ gives rise to a 2-dimensional mod $p$ representation

$$\bar{\rho}_{F,p} : \text{Gal}((\overline{\mathbb{Q}})/\mathbb{Q}) \rightarrow \text{GL}_2(\mathbb{F}_p).$$

Suppose $\bar{\rho}_{F,p}$ is irreducible (that is, $F$ does not have an $p$-isogeny); this can often be established by appealing to Mazur’s isogeny theorem [1978]. A standard consequence of Ribet’s lowering theorem [1990], building on the modularity of elliptic curves over $\mathbb{Q}$ due to Wiles and others [Wiles 1995; Breuil et al. 2001], is that $\bar{\rho}_{F,p}$ arises from a weight-2 newform of level $\ell$. More precisely, there is a newform $f$ of weight 2 and level $N$ with normalized $q$-expansion

$$f = q + \sum_{m=2}^{\infty} c_m q^m$$

such that

$$\bar{\rho}_{F,p} \sim \bar{\rho}_{f,p},$$

where $p$ is a prime ideal above $p$ of the ring of integers $\mathcal{O}_f$ of the Hecke eigenfield $K_f = \mathbb{Q}(c_1, c_2, \ldots)$. The original motivation for the great theorems of Ribet and Wiles included Fermat’s last theorem. To motivate what is to come in later sections, we quickly sketch the deduction of FLT from the above. Let $x, y, z$ be nonzero coprime rational integers satisfying $x^p + y^p + z^p = 0$ where $p \geq 5$ is prime. After appropriately permuting $x, y, z$, we may suppose that $2 \mid y$ and that $x^n \equiv -1 \pmod{4}$. Let $F$ be the Frey–Hellegouarch curve

$$Y^2 = X(X - x^p)(X + y^p).$$

It follows from Mazur’s isogeny theorem and related results that $\bar{\rho}_{E,p}$ is irreducible. A short computation reveals that

$$\Delta_F = 2^{-8}(xyz)^{2p} \quad \text{and} \quad N_F = 2 \text{Rad}(xyz),$$

where $\text{Rad}(m)$ denotes the product of the prime divisors of $m$. We find that $N = 2$. Thus $\bar{\rho}_{F,p}$ arises from a newform $f$ of weight 2 and level 2; the nonexistence of such newforms provides the desired contradiction.

It is possible to use a similar strategy to treat various Diophantine problems including generalized Fermat equations $Ax^p + By^q = Cz^r$, for certain signatures $(p, q, r)$. This is done by Kraus [1997] for signature $(p, p, p)$ and by Bennett and Skinner [2004] for signature $(p, p, 2)$. Fortunately, these papers provide recipes for the Frey–Hellegouarch curves $F$ and for the levels $N$, and establish the required
irreducibility of $\tilde{\rho}_{F,n}$. We shall make frequent use of these recipes in later sections. It is known (and easily checked using standard dimension formulae) that there are no weight-2 newforms at levels

$$1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 13, 16, 18, 22, 25, 28, 60, \tag{39}$$

but there are newforms at all other levels. Thus, if the level $N$ predicted by the recipes is not in the list (39) then we do not immediately obtain a contradiction. Instead, we may compute the possible newforms using implementations (for example, in Magma or SAGE) of modular symbols algorithms due to Cremona [1997] and Stein [2007]. We then use the relation (38) to help us extract information about the solutions to our Diophantine equation. In doing this, we shall often make use of the following standard result; see, for example, [Kraus and Oesterlé 1992; Siksek 2012, Section 5].

**Lemma 7.1.** Let $F/\mathbb{Q}$ be an elliptic curve of conductor $N_F$. Let $f$ be a weight-2 newform of level $N$ having $q$-expansion as in (37). Suppose (38) holds for some prime $p \geq 5$. Let $\ell \neq p$ be a rational prime.

(i) If $\ell \mid N_F$ then $a_\ell(F) \equiv c_\ell \pmod{p}$.

(ii) If $\ell \nmid N_F$ but $\ell \mid| N_F$ then $\ell + 1 \equiv \pm c_\ell \pmod{p}$.

If $f$ is a rational newform (i.e., $K_f = \mathbb{Q}$) then (i), (ii) also hold for $\ell = p$.

We will also make frequent use of the following theorem.

**Theorem 8** [Kraus 1997, Proposition 2]. Let $f$ be a newform of weight 2 and level $N$ with $q$-expansion as in (37), and Hecke eigenfield $K_f$ with ring of integers $\mathcal{O}_f$. Write

$$M = \text{lcm}(4, N) \quad \text{and} \quad \mu(M) = M \cdot \prod_{\substack{r \mid M \\text{prime} \atop r \mid M}} \left(1 + \frac{1}{r}\right).$$

Let $\mathfrak{p}$ be a prime ideal of $\mathcal{O}_f$ and suppose the following two conditions hold.

(i) For all primes $\ell \leq \mu(M)/6$, $\ell \mid 2N$, we have

$$\ell + 1 \equiv c_\ell \pmod{p}.$$

(ii) For all primes $\ell \leq \mu(M)/6$, $\ell \mid 2N$, $\ell^2 \mid 4N$, we have

$$(\ell + 1)(c_\ell - 1) \equiv 0 \pmod{p}.$$  

Then $\ell + 1 \equiv c_\ell \pmod{p}$ for all primes $\ell \mid 2N$.

8. **The equation $x^2 - q^{2k} = y^n$ with $y$ even: an approach via Frey curves**

We are still concerned with (31). In view of the results of Section 6, we may suppose that $n \geq 7$ is prime. To show that (31) has no solutions for a particular pair $(q, n)$, it is enough to show the same for (36). We shall think of (36) as a Fermat equation of signature $(n, n, n)$ by writing it as $y_1^n - 2^{n-2}y_2^n = q^k \cdot 1^n$. This enables us to apply recipes of Kraus [1997] for Frey–Hellegouarch curves and level lowering. The following lemma will eliminate some cases when applying those recipes.
Lemma 8.1. Suppose \( n \geq 7 \) is prime. Then \( \gcd(k, 2n) = 1 \).

Proof: Theorem 1.2 of [Bennett and Skinner 2004] asserts that the equation \( A^p + 2^\alpha B^p = C^2 \) with prime \( p \geq 7 \) has no solutions in nonzero integers with \( \gcd(A, B, C) = 1 \) and \( \alpha \geq 2 \). It immediately follows from (36) that \( k \) is odd. Moreover, Theorem 3 of [Ribet 1997] asserts that the equation \( A^p + 2^\alpha B^p + C^p = 0 \) has no solutions with \( ABC \neq 0 \) for prime \( p \geq 7 \) and \( 2 \leq \alpha \leq p - 1 \). It follows that \( n \nmid k \). □

Following Kraus, we attach to a solution of (36) a Frey–Hellegouarch curve \( F \), where

\[
F : Y^2 = X(X + y_1^n)(X + 2^{n-2}y_2^n) \quad (40)
\]

if \( q \equiv 1 \pmod{4} \), and

\[
F : Y^2 = X(X - q^k)(X + 2^{n-2}y_2^n), \quad (41)
\]

if \( q \equiv 3 \pmod{4} \). The Frey–Hellegouarch curve \( F \) is semistable, and has minimal discriminant and conductor, respectively, given by

\[
\Delta_F = 2^{2n-12}q^{2k}(y_1y_2)^n \quad \text{and} \quad N_F = 2q \cdot \text{Rad}_2(y_1y_2), \quad (42)
\]

where \( \text{Rad}_2(m) \) denotes the product of the odd primes dividing \( m \). From Kraus [1997], the mod \( n \) representation of \( F \) arises from a newform \( f \) of weight 2 and level \( N = 2q \).

Let \( \ell \nmid 2q \) be a prime. Write

\[
T = \{ a \in \mathbb{Z} \cap [-2\sqrt{\ell}, 2\sqrt{\ell}] : a \equiv \ell + 1 \pmod{4} \}.
\]

Let

\[
D'_{f,\ell} = ((\ell + 1)^2 - c_\ell^2) \cdot \prod_{a \in T} (a - c_\ell),
\]

and

\[
D_{f,\ell} = \begin{cases} 
\ell \cdot D'_{f,\ell} & \text{if } K_f \neq \mathbb{Q}, \\
D'_{f,\ell} & \text{if } K_f = \mathbb{Q}, 
\end{cases}
\]

Lemma 8.2. Let \( f \) be a newform of weight 2 and level \( 2q \), and suppose that (38) holds. Let \( \ell \nmid 2q \) be a prime. Then \( n \mid D_{f,\ell} \).

Proof. If \( \ell \nmid y_1y_2 \), then \( \ell \nmid N_F \) and so is a prime of good reduction for \( F \). As \( F \) has full 2-torsion we deduce that \( 4 \mid (\ell + 1 - a_\ell(F)) \). By the Hasse–Weil bounds, \( a_\ell(F) \) belongs to the set \( T \). If \( \ell \mid y_1y_2 \), then \( \ell \mid N_F \). The lemma now follows from Lemma 7.1. □

It is straightforward from Lemma 8.2 and the fact that \( n \mid n \) that \( n \mid \text{Norm}(D_{f,\ell}) \). Thus if \( D_{f,\ell} \neq 0 \), we immediately obtain an upper bound upon the exponent \( n \). This approach will result in a bound on the exponent \( n \) in (31) unless \( f \) corresponds to an elliptic curve over \( \mathbb{Q} \) with full 2-torsion and conductor \( N = 2q \); for this see [Siksek 2012, Section 9]. Mazur showed that such an elliptic curve exists if and only if \( q \geq 31 \) is a Fermat or a Mersenne prime; see, for example, [Siksek 2012, Theorem 8]. We note that 31, 127 and 257 are the only such primes in our range \( 3 \leq q < 1000 \). We shall exploit this approach to prove the following.
Proposition 8.3. Let $n \geq 7$ and $3 \leq q < 1000$ be primes.

(i) If $q \not\in \{31, 127, 257\}$, then (31) has no solutions.

(ii) Suppose $q \in \{31, 127, 257\}$, write $q = 2^m + \eta$ where $\eta = \pm 1$, and let

$$E_q : Y^2 = X(X + 1)(X - \eta \cdot 2^m).$$

(43)

Suppose $(k, x, y)$ is a solution to (31) and let $F$ be as above. Then

$$\tilde{\rho}_{F, n} \sim \tilde{\rho}_{E_q, n}.$$  

In Cremona’s notation, these $E_q$ are the elliptic curves 62a2, 254d2 and 514a2, for $q = 31, 127$ and 257, respectively.

Proof: There are no newforms of weight 2 and levels 6, 10 and 22. Therefore the proof is complete in the cases where $q \in \{3, 5, 11\}$. We may thus suppose that $7 \leq q < 1000$ is prime and that $q \neq 11$.

For a newform $f$ of weight 2 and level $2q$, and a collection of primes $\ell_1, \ldots, \ell_m$ (all coprime to $2q$), we write $D_{f, \ell_1, \ldots, \ell_m}$ for the ideal of $\mathcal{O}_f$ generated by $D_{f, \ell_1}, \ldots, D_{f, \ell_m}$. Let $B_{f, \ell_1, \ldots, \ell_m} \in \mathbb{Z}$ be the norm of the ideal $D_{f, \ell_1, \ldots, \ell_m}$. If $\tilde{\rho}_{F, n} \sim \tilde{\rho}_{f, n}$, then $n \mid D_{f, \ell_1, \ldots, \ell_m}$ by Lemma 8.2. As $n \mid n$, we deduce that $n \mid B_{f, \ell_1, \ldots, \ell_m}$. In our computations we will take $\ell_1, \ldots, \ell_m$ to be all the primes $< 200$ distinct from 2 and $q$, and write $B_f$ for $B_{f, \ell_1, \ldots, \ell_m}$.

We wrote a short Magma script which computed, for all newforms $f$ at all levels $2q$ under consideration, the integer $B_f$. We found that $B_f \neq 0$ for all newforms $f$ except for three rational newforms of levels 62, 254 and 514 (corresponding to $q = 31, 127$ and 257, respectively). Thus, for all other newforms, we at least obtain a bound on $n$. In many cases this bound is already sharp enough to contradict our assumption that $n \geq 7$. We give a few examples.

Let $q = 13$. Then there are two eigenforms $f_1, f_2$ of level $2q = 26$, and

$$B_{f_1} = 3 \times 5, \quad B_{f_2} = 3 \times 7.$$  

Thus we eliminate $f_1$ from consideration, and also conclude that $n = 7$. It is natural to wonder if $n = 7$ can be eliminated by increasing the size of our set of primes $\ell_1, \ldots, \ell_m$, but this is not the case. The newform $f_2$ is rational and corresponds to the elliptic curve 26b1 with Weierstrass model

$$E' : Y^2 + XY + Y = X^3 - X^2 - 3X + 3.$$  

The torsion subgroup of $E'\left(\mathbb{Q}\right)$ is isomorphic to $\mathbb{Z}/7\mathbb{Z}$, generated by the point $(1, 0)$. In particular, for any prime $\ell \mid 26$, we have $7 \mid (\ell + 1 - a_\ell(E'))$. Since $a_\ell(E') = c_\ell(f_2)$, we have $7 \mid B_{f_2, \ell}$. Thus $7 \mid B_{f, \ell_1, \ldots, \ell_m}$ regardless of the set of primes $\ell_1, \ldots, \ell_m$ that we choose. However we can still obtain a contradiction for $n = 7$ in this case. Indeed, we have $\tilde{\rho}_{F, 7} \sim \tilde{\rho}_{f_2, 7} \sim \tilde{\rho}_{E', 7}$. Since $E'$ has nontrivial 7-torsion, the representation $\tilde{\rho}_{E', 7}$ is reducible. However, the representation of the Frey curve $\tilde{\rho}_{F, 7}$ is irreducible as shown by Kraus [1997, Lemme 4], contradicting the fact that $F$ has full rational 2-torsion.
For \( q = 31 \), there are two newforms, \( g_1 \) and \( g_2 \). We find that \( B_{g_1} = 0 \) and \( B_{g_2} = 2^3 \times 3^2 \); thus we may eliminate \( g_2 \) for consideration. The eigenform \( g_1 \) is rational and corresponds to the elliptic curve \( E_{31} \) with Cremona label 62a2. Hence \( \tilde{\rho}_{F,p} \sim \tilde{\rho}_{g_1,p} \sim \tilde{\rho}_{E_{31},p} \), whence the proof is complete for \( q = 31 \).

For \( q = 37 \), there are two newforms, \( h_1 \) and \( h_2 \). We find that \( B_{h_1} = 3^3 \) and \( B_{h_2} = 19 \). Thus \( n = 19 \) and

\[
\tilde{\rho}_{F,19} \sim \tilde{\rho}_{h_2,19}.
\]

The newform \( h_2 \) has \( q \)-expansion

\[
h_2 = q + q^2 + \alpha q^3 + q^4 + (-3\alpha - 1)q^5 + \alpha q^6 + 2\alpha q^7 + \cdots,
\]

where \( \alpha = \frac{-1 + \sqrt{5}}{2} \), and Hecke eigenfield \( K = \mathbb{Q}(\sqrt{5}) \). Let \( n \) be the prime ideal \( n = (4 - \alpha) \cdot O_K \) having norm 19. We checked, using Theorem 8, that \( \ell + 1 \equiv c_\ell \pmod{n} \) for all primes \( \ell \not| 2 \cdot 37 \), where \( c_\ell \) is the \( \ell \)-th coefficient of \( h_2 \). From relation (44), we know that

\[
a_\ell(F) \equiv c_\ell \pmod{n}
\]
for all primes \( \ell \) of good reduction for \( F_{3,1} \). Thus 19 \( \mid (\ell + 1 - a_\ell(F_{3,1})) \) for all primes \( \ell \) of good reduction.

As before, this now implies that \( \tilde{\rho}_{F,19} \) is reducible [Serre 1975, IV-6], giving a contradiction. The proof is thus complete for \( q = 37 \).

The above arguments allow us to prove (ii) in the statement of the proposition, and to obtain a contradiction for all \( 3 \leq q < 1000, q \not\in \{31, 127, 257\} \), except when \( n = 7 \) and \( q \) belongs to the list

\[
43, 101, 103, 139, 163, 379, 467, 509, 557, 569, 839, 937, 947, 977.
\]

For \( n = 7 \) and these values of \( q \), we checked using the aforementioned Thue–Mahler solver that the only solutions to (36) are \((y_1, y_2, k) = (1, 0, 0)\). Since \( k \not= 0 \) in (31), the proof is complete. \( \square \)

**Symplectic criteria.** When \( q \geq 31 \) is a Fermat or Mersenne prime, it does not seem to be possible, working purely with Galois representations of elliptic curves, to eliminate the possibility that \( \tilde{\rho}_{F,n} \sim \tilde{\rho}_{E_q,n} \). However, the so-called ‘symplectic method’ of Halberstadt and Kraus [2002] allows us to derive an additional restriction on the solutions to (31).

**Lemma 8.4.** Let \( q = 2^m + \eta \) be a Fermat or Mersenne prime. Let \( n \geq 7 \) be a prime \( \neq q \). Suppose \((x, y, k)\) is a solution to (31), and let \( F \) be the Frey–Hellegouarch curve constructed above, and \( E_q \) be given by (43). Suppose \( \tilde{\rho}_{F,n} \sim \tilde{\rho}_{E_q,n} \). Then either \( n \mid (m - 4) \) or

\[
\left( \frac{(24 - 6m)k}{n} \right) = 1.
\]

**Proof.** We note that the curves \( F \) and \( E_q \) have multiplicative reduction at both 2 and \( q \). Write \( \Delta_1 \) and \( \Delta_2 \) for the minimal discriminants of \( F \) and \( E_q \), respectively. By [Halberstadt and Kraus 2002, Lemme 1.6], the ratio

\[
\frac{\text{ord}_2(\Delta_1) \cdot \text{ord}_q(\Delta_1)}{\text{ord}_2(\Delta_2) \cdot \text{ord}_q(\Delta_2)}
\]
is a square modulo $n$, provided $n \nmid \text{ord}_2(\Delta_i)$, $n \nmid \text{ord}_q(\Delta_i)$. It is in invoking this result of Halberstadt and Kraus that we require the assumption that $n \neq q$. We find that

$$\Delta_1 = 2^{2n-12} q^{2k} (y_1 y_2)^{2n} \quad \text{and} \quad \Delta_2 = 2^{2m-8} q^2.$$ 

We have previously noted that $n \nmid k$ by appealing to a result of Ribet. Suppose $n \nmid (m - 4)$. Then the valuations $\text{ord}_2(\Delta_i)$ and $\text{ord}_q(\Delta_i)$ are all indivisible by $n$. The result follows.

9. The equation $x^2 - q^{2k} = y^n$: an upper bound for the exponent $n$

To help us complete the proof of Theorem 5, we begin by deriving an upper bound for $n$. Our approach is essentially a minor sharpening of Theorem 3 of [Bugeaud 1997] in a slightly special case. Since this result is valid for an arbitrary prime $q$, it may be of independent interest.

**Theorem 9.** Let $x$, $y$, $q$, $k \geq 1$ and $n \geq 3$ be integers satisfying (7), with $n$ and $q$ prime, and $q \nmid x$. Then

$$n < 1000 q \log q.$$ 

**Proof.** If $q = 2$, then we have that $n \leq 5$ from Theorem 1.2 of [Bennett and Skinner 2004]. We may thus suppose that $q$ is odd and, additionally, that $y$ is even, or, via Proposition 3.1, we immediately obtain the much stronger result that $n \mid (q - 1)$. We are therefore in case (35). By Proposition 8.3, we may suppose that $q = 31$ or that $q \geq 127$. Set $Y = \max\{|y_1|, |2y_2|\}$ and suppose first that

$$q^k \geq Y^{n/2},$$

or equivalently

$$2k \log q \geq n \log Y.$$  

(47)

We set

$$\Lambda = \frac{q^k}{(2y_2)^n} \left( \frac{y_1}{2y_2} \right)^n - \frac{1}{4};$$

we wish to apply an upper bound for linear forms in $q$-adic logarithms to $\Lambda$, in order to bound $k$. To do this, we must first treat the case where $y_1/2y_2$ and $1/4$ are multiplicatively dependent, i.e., where $y_1 y_2$ has no odd prime divisors. Under this assumption, since $y_1$ is odd, we find from (36) that

$$2^{j} \pm 1 = q^k,$$

for an integer $j$ with $j \equiv -2 \pmod{n}$. Via Mihăilescu’s theorem [2004], if $n \geq 7$, necessarily $k = 1$, $y_1 = \pm 1$, $y_2 = -2^\kappa$ for some integer $\kappa$ and

$$q = 2^{(\kappa+1)n-2} \pm 1.$$ 

In this case, we find a solution to (7) corresponding to the identity

$$(-q \pm 2)^2 - q^2 = 4 \mp 4q = (\mp 2^{k+1})^n,$$

whereby, certainly $n < 1000 q \log q$. 

Otherwise, we may suppose that $y_1/2y_2$ and $\frac{1}{4}$ are multiplicatively independent and that $Y \geq 3$. We will appeal to Théorème 4 of Bugeaud and Laurent [1996], with, in the notation of that result, $(\mu, \nu) = (10, 5)$ (see also Proposition 1 of Bugeaud [1997]). Before we state this result, we require some notation. Let $\overline{Q}_q$ denote an algebraic closure of the $q$-adic field $Q_q$, and define $\nu_q$ to be the unique extension to $\overline{Q}_q$ of the standard $q$-adic valuation over $Q_q$, normalized so that $\nu_q(q) = 1$. For any algebraic number $\alpha$ of degree $d$ over $Q$, define the absolute logarithmic height of $\alpha$ via the formula

$$h(\alpha) = \frac{1}{d} \left( \log |a_0| + \sum_{i=1}^{d} \log \max(1, |\alpha^{(i)}|) \right), \quad (48)$$

where $a_0$ is the leading coefficient of the minimal polynomial of $\alpha$ over $Z$ and the $\alpha^{(i)}$ are the conjugates of $\alpha$ in $C$.

**Theorem 10** (Bugeaud–Laurent). Let $q$ be a prime number and let $\alpha_1, \alpha_2$ denote algebraic numbers which are $q$-adic units. Let $f$ be the residual degree of the extension $Q_q(\alpha_1, \alpha_2)/Q_q$ and put

$$D = \left[ Q_q(\alpha_1, \alpha_2) : Q_q \right] / f.$$ 

Let $b_1$ and $b_2$ be positive integers and put

$$\Lambda_1 = \alpha_1^{b_1} - \alpha_2^{b_2}.$$ 

Denote by $A_1 > 1$ and $A_2 > 1$ real numbers such that

$$\log A_i \geq \max\left\{ h(\alpha_i), \frac{\log q}{D} \right\}, \quad i \in \{1, 2\},$$

and put

$$b' = \frac{b_1}{D \log A_2} + \frac{b_2}{D \log A_1}.$$ 

If $\alpha_1$ and $\alpha_2$ are multiplicatively independent, then we have the bound

$$\nu_q(\Lambda_1) \leq \frac{24q(q^f - 1)}{(q - 1) \log^4 q} D^4 \left( \max\left\{ \log b' + \log \log q + 0.4, \frac{10 \log q}{D}, 5 \right\} \right)^2 \cdot \log A_1 \cdot \log A_2.$$ 

We apply this with

$$f = 1, \quad D = 1, \quad \alpha_1 = \frac{y_1}{2y_2}, \quad \alpha_2 = \frac{1}{4}, \quad b_1 = n, \quad b_2 = 1,$$

so that we may choose

$$\log A_1 = \max\{\log Y, \log q\}, \quad \log A_2 = \max\{2 \log 2, \log q\},$$

and

$$b' = \frac{n}{\log A_2} + \frac{1}{\log A_1}.$$ 

Let us assume now that

$$n \geq 1000 q \log q, \quad (49)$$
whilst recalling that either \( q = 31 \) or \( q \geq 127 \). We therefore have

\[
b' < 1.001 \frac{n}{\log q}
\]

and hence find that

\[
k \leq 24 \frac{q}{\log^3 q} (\max\{\log n + 0.401, 10 \log q\})^2 \log A_1.
\]

whence, from (47),

\[
n \log Y \leq 48 \frac{q}{\log^2 q} (\max\{\log n + 0.401, 10 \log q\})^2 \log A_1.
\]

Let us suppose first that

\[
\log n + 0.401 \geq 10 \log q.
\]

If \( q \geq Y \), we have that \( \log A_1 = \log q \) and hence

\[
\frac{n \log Y}{(\log n + 0.401)^2} \leq 48 \frac{q}{\log q}.
\]

From (49), we thus have

\[
\frac{\log^2 q}{(\log(1000 q \log q) + 0.401)^2} \leq \frac{0.048}{\log Y} \leq \frac{0.048}{\log 3},
\]

contradicting \( q \geq 31 \). If, on the other hand, \( q < Y \), then \( \log A_1 = \log Y \) and so

\[
\frac{n}{(\log n + 0.401)^2} \leq 48 \frac{q}{\log^2 q}.
\]

With (49), this implies that

\[
\log^3 q < 0.048(\log(1000 q \log q) + 0.401)^2,
\]

again contradicting \( q \geq 31 \).

We may therefore assume that

\[
\log n + 0.401 < 10 \log q,
\]

so that

\[
n \log Y \leq 4800 q \log A_1.
\]

If \( q \geq Y \), then, from (49),

\[
\log Y < 4.8,
\]

whereby \( 3 \leq Y \leq 121 \). If \(|y_1| \geq 2|y_2|\), it follows from (36) that

\[
q^k \geq |y_1|^n - \frac{1}{4} |y_1|^n = \frac{3}{4} Y^n.
\]

Suppose, conversely, that \(|y_1| \leq 2|y_2| - 1\) (so that \( 1 \leq |y_2| \leq 60 \)). If \( y_1 > 0 \) and \( y_2 < 0 \), it follows from (36) that

\[
q^k > \frac{1}{4} Y^n.
\]
We may thus suppose that $y_1$ and $y_2$ have the same sign, whence, from (36), (49) and $|y_2| \leq 60$,

\[ q^k = 2^{n-2}|y_2|^n - |y_1|^n > 0.24 \cdot |2y_2|^n = 0.24 \cdot Y^n. \]  

Combining (53), (54) and (55), we thus have from (50) that

\[ n \log Y + \log 0.24 < k \log q \leq 2400 \cdot q \log q, \]

contradicting (49) and $q \geq 31$. If $q < Y$, then, via (49),

\[ 1000 \cdot q \log q \leq n \leq 4800 \cdot q, \]  

(56)

a contradiction for $q \geq 127$. We may thus suppose that $q = 31$, $Y > 31$ and, from (52), $n \leq 12119$, which contradicts (49).

Next suppose that inequality (46) (and hence also inequality (47)) fails to hold. In this case, we will apply lower bounds for linear forms in two complex logarithms. Following Bugeaud, we take

\[ \log |3_1| = 2 \log 2 + k \log q - n \log |2y_2|, \]  

(57)

If $Y = \max(|y_1|, |2y_2|) = |y_1|$, then, from (35), it follows that

\[ q^k \geq \frac{3}{4} |y_1|^n = \frac{3}{4} Y^n, \]

contradicting $q^k < Y^{n/2}$. It follows that $Y = |2y_2|$ and so, from (57),

\[ \log |\Lambda_1| = 2 \log 2 + k \log q - n \log Y \leq 2 \log 2 - \frac{n}{2} \log Y. \]  

(58)

From (49), we have that $|\Lambda_1| \leq \frac{1}{2000}$, so that

\[ \left| n \log \left( \frac{2y_2}{y_1} \right) - 2 \log 2 \right| \leq |\log(1 - \Lambda_1)| \leq 1.001 \cdot |\Lambda_1|. \]  

(59)

We will appeal to the following.

**Theorem 11** [Laurent 2008, Corollary 1]. *Consider the linear form*

\[ \Lambda = c_2 \log \beta_2 - c_1 \log \beta_1, \]

where $c_1$ and $c_2$ are positive integers, and $\beta_1$ and $\beta_2$ are multiplicatively independent algebraic numbers. *Define $D = [\mathbb{Q}(\beta_1, \beta_2) : \mathbb{Q}] / [\mathbb{R}(\beta_1, \beta_2) : \mathbb{R}]$ and set*

\[ b' = \frac{c_1}{D \log B_2} + \frac{c_2}{D \log B_1}, \]

where $B_1, B_2 > 1$ are real numbers such that

\[ \log B_i \geq \max \left\{ h(\beta_i), \frac{|\log \beta_i|}{D}, \frac{1}{D} \right\}, \quad i \in \{1, 2\}. \]
Then
\[ \log |\Lambda| \geq -CD^4 \left( \max \left\{ \log b' + 0.21, \frac{m}{D}, 1 \right\} \right)^2 \log B_1 \log B_2, \]
for each pair \((m, C)\) in the following set
\( \{(10, 32.3), (12, 29.9), (14, 28.2), (16, 26.9), (18, 26.0), (20, 25.2), (22, 24.5), (24, 24.0), (26, 23.5), (28, 23.1), (30, 22.8)\}. \)
Applying this result to the left-hand side of (59), with \((m, C) = (10, 32.3)\),
\[ \beta_2 = \frac{2y_2}{y_1}, \quad \beta_1 = 4, \quad c_2 = n, \quad c_1 = 1, \quad D = 1, \]
\[ \log B_2 = \log Y, \quad \log B_1 = 2 \log 2 \quad \text{and} \quad b' = \frac{n}{2 \log 2} + \frac{1}{\log Y} < \frac{1.001n}{2 \log 2}, \]
we may conclude that
\[ \log |\Lambda_1| \geq -0.001 - 44.8(\max\{\log n - 0.11, 10\})^2 \log Y. \]
Combining this with (58), we thus have
\[ n \leq 89.6(\max\{\log n - 0.11, 10\})^2 + \frac{1.4}{\log Y}. \]
After a little work we find that
\[ n \leq 8961, \]
contradicting (49) and \(q \geq 31. \)

10. The equation \(x^2 - q^{2k} = y^n\): proof of Theorem 5

In this section, we complete the proof of Theorem 5. Let \(3 \leq q < 1000\) be a prime and let \((k, x, y, n)\) be a solution to (7) where \(x, k \geq 1\) and \(n \geq 3\) are positive integers satisfying \(q \nmid x\). Thanks to Lemmata 3.2, 6.1 and 6.2, we may suppose that \(y\) is even and that \(n \geq 7\) is prime. It follows from Proposition 8.3 that \(q = 31, 127\) or 257 and \(\tilde{\rho}_{F,n} \sim \tilde{\rho}_{E_q,n}\), where \(E_q\) is given in (43), and \(F\) is the Frey–Hellegouarch curve given in (40) or (41) according to whether \(q \equiv 1\) or 3 (mod 4). From Theorem 9, we have
\[ n < 1000 \times 257 \times \log 257 < 1.5 \times 10^6. \]
We now give a method, which for a given exponent \(n\) and prime \(q \in \{31, 127, 257\}\), is capable of showing that (36) has no solutions. This is an adaptation of the method called ‘predicting the exponents of constants’ in [Siksek 2012, Section 13]. Let \(n \geq 7\) be prime and choose \(\ell \neq q\) to be a prime satisfying
(i) \(\ell = tn + 1\) for some positive integer \(t\);
(ii) \(n \nmid ((\ell + 1)^2 - a_\ell(E_q))^2\).
For \( \kappa \in \mathbb{F}_\ell, \kappa \notin \{0, 1\} \), set
\[
E(\kappa) : Y^2 = X(X - 1)(X - \kappa).
\]
Let \( g \) be a primitive root for \( \ell \) (that is, a generator for \( \mathbb{F}_\ell^\ast \)) and let \( h = g^n \). Define \( X_\ell \subset \mathbb{F}_\ell^\ast \) via
\[
X_\ell = \left\{ \frac{1}{4} h^r : 0 \leq r \leq t - 1 \text{ and } h^r \not\equiv 4 \pmod{\ell} \right\}
\]
and
\[
Y_\ell = \{(\kappa - 1) \cdot (\mathbb{F}_\ell^*)^n : \kappa \in X_\ell \text{ and } a_\ell(E(\kappa))^2 \equiv a_\ell(E_q)^2 \pmod{n}\} \subset \mathbb{F}_\ell^*/(\mathbb{F}_\ell^*)^n.
\]
Define further
\[
\phi : \mathbb{Z}/n\mathbb{Z} \to \mathbb{F}_\ell^*/(\mathbb{F}_\ell^*)^n \quad \text{via} \quad \phi(s) = q^s \cdot (\mathbb{F}_\ell^*)^n.
\]
Finally, let
\[
Z_\ell = \left\{ s \in \phi^{-1}(Y_\ell) : \left(\frac{(24 - 6m)s}{n}\right) = 1 \right\}.
\]
where \( q = 2^m \pm 1 \); thus \( m = 5, 7 \) and \( 8 \) for \( q = 31, 127 \) and \( 257 \), respectively. We note that \( n \nmid (m - 4) \) in all cases, so that (45) holds.

**Lemma 10.1.** Let \( q \in \{31, 127, 257\} \) and \( n \geq 7, n \neq q \) be prime. Let \( \ell_1, \ldots, \ell_t \) be primes \( \neq q \) satisfying (i) and (ii) above, and also
\[
\bigcap_{i=1}^{t} Z_{\ell_i} = \emptyset. \tag{60}
\]
Then (7) has no solutions with \( k \geq 1 \) and \( q \nmid x \).

**Proof.** From Proposition 8.3, \( \tilde{\rho}_{F,n} \sim \tilde{\rho}_{E_q,n} \). The minimal discriminant and conductor of \( F \) are given in (42). Thus a prime \( \ell \nmid 2q \) satisfies \( \ell \mid N_F \) if and only if \( \ell \mid y_1y_2 \), otherwise \( \ell \nmid N_F \). Let \( \ell \neq q \) be a prime satisfying (i) and (ii). By (ii) we know, thanks to Lemma 7.1, that \( \ell \mid y_1y_2 \), and so \( a_\ell(F) \equiv a_\ell(E_q) \pmod{n} \). Let \( \kappa \in \mathbb{F}_\ell \) satisfy
\[
\kappa \equiv \frac{2n-2y_2^n}{y_1^n} \pmod{\ell}.
\]
Then \( E(\kappa)/\mathbb{F}_\ell \) is a quadratic twist of \( F/\mathbb{F}_\ell \) and so \( a_\ell(E(\kappa)) = \pm a_\ell(F) \). We conclude that \( a_\ell(E(\kappa))^2 \equiv a_\ell(E_q)^2 \pmod{n} \).

Recall that \( \ell = tn + 1 \) and \( h = g^n \), where \( g \) is a primitive root of \( \mathbb{F}_\ell \). Observe that
\[
4\kappa \equiv \frac{2y_2^n}{y_1^n} \equiv h^r \pmod{\ell},
\]
for some \( 0 \leq r \leq t - 1 \). Moreover,
\[
\kappa - 1 \equiv \frac{2n-2y_2^n}{y_1^n} - 1 \equiv -q^k \pmod{\ell},
\]
for some \( 0 \leq k \leq t - 1 \) and
\[
q^k \equiv -\frac{y_1^n}{y_2^n} \pmod{\ell}.
\]
In particular, \( \kappa \neq 1 \) and so \( \kappa \in \mathcal{X}_\ell \) and \( q^k \cdot (\mathbb{F}_p^*)^n = (\kappa - 1) \cdot (\mathbb{F}_p^*)^n \in \mathcal{Y}_\ell \). Hence \( s \in \phi^{-1}(\mathcal{Y}_\ell) \), where \( s = \bar{k} \in \mathbb{Z}/n\mathbb{Z} \). Since \( k \) also satisfies (45), we conclude that \( s \in \mathcal{Z}_\ell \). As this is true for \( \ell = \ell_1, \ldots, \ell_t \), the element \( s \) belongs to the intersection (60) giving a contradiction.

\[ \square \]

**Corollary 10.2.** For \( q \in \{31, 127, 257\} \) and prime \( n \) with \( 7 \leq n < 1.5 \times 10^6 \), equation (7) has no solutions with \( k \geq 1 \) and \( q \nmid x \).

**Proof.** For \( n \neq q \), we ran a short Magma script that searches for suitable primes \( \ell_i \) and verifies the criterion of Lemma 10.1. This succeeded for all the primes \( 7 \leq n < 1.5 \times 10^6 \) in a few minutes, except for \((q, n) = (31, 7)\). In this case, we found that \( \bigcap \mathcal{Z}_{\ell_i} = \{1\} \) no matter how many primes \( \ell_i \) we chose. The reason for this is that there is a solution to (36) with \( n = 7 \) and \( k = 1 \), namely \((-1)^7 - 2^5 \cdot (-1)^7 = 31^1\).

In the case \( n = q \), we are unable to appeal directly to Lemma 10.1 as we no longer necessarily have (45). We can, however, still derive a slightly weaker analogue of Lemma 10.1 with the \( \mathcal{Z}_\ell \) replaced by the (typically) larger sets

\[ \mathcal{Z}'_\ell = \phi^{-1}(\mathcal{Y}_\ell). \]

For \( n = q \), we find that

\[ \mathcal{Z}'_{311} \cap \mathcal{Z}'_{373} = \emptyset, \quad \mathcal{Z}'_{309} \cap \mathcal{Z}'_{2287} = \emptyset \quad \text{and} \quad \mathcal{Z}'_{1543} = \emptyset, \]

for \( q = 31, 127 \) and \( 257 \), respectively.

To complete the proof of Theorem 5, it remains only to solve the Thue–Mahler equation

\[ y_1^7 - 32y_2^7 = 31^k. \]

Using the Magma implementation of [Gherga and Siksek 2022], we find that the only solution with \( k \) positive is with \( k = 1 \) and \( y_1 = y_2 = -1 \), corresponding to the solution \((q, k, y, n) = (31, 1, 2, 7)\) to (7).

\[ \square \]

**11. The equation \( x^2 + q^{2k+1} = y^n \) with \( y \) odd**

In previous sections, we have completed the proofs of Theorems 4 and 5, therefore solving (8) with \( 3 \leq q < 1000 \) prime, for even exponents \( \alpha \). The remainder of the paper is devoted to solving (8) for odd exponents \( \alpha \), and for the more modest range \( 3 \leq q < 100 \). In this section, we focus on the equation

\[ x^2 + q^{2k+1} = y^n, \quad x, y, k \text{ integers, } k \geq 0, \gcd(x, y) = 1, \ y \text{ odd}, \]

with exponent \( n \geq 5 \) prime; here \( q \geq 3 \) is prime.

**Theorem 12** (Arif and Abu Muriefah). Suppose \( q \geq 3 \) and \( n \geq 5 \) are prime, and that \( n \) does not divide the class number of \( \mathbb{Q}(\sqrt{-q}) \). Then the only solution to (61) corresponds to the identity

\[ 22434^2 + 19 = 55^5. \]

**Proof.** The proof given by Arif and Abu Muriefah [2002] is somewhat lengthy and slightly incorrect. For the convenience of the reader we give a corrected and simplified proof. Let \( M = \mathbb{Q}(\sqrt{-q}) \) and
suppose that $n$ does not divide the class number of $M$. This and the assumptions in (61) quickly lead us to conclude that

$$x + q^k \sqrt{-q} = \alpha^n$$

for some $\alpha \in \mathcal{O}_M$ with $\text{Norm}(\alpha) = y$. Thus

$$\alpha^n - \bar{\alpha}^n = 2q^k \sqrt{-q}.$$ (63)

If $\alpha/\bar{\alpha}$ is a root of unity, then by the coprimality of $\alpha$ and $\bar{\alpha}$, we can conclude that $\alpha$ is a unit and so $y = 1$ giving a contradiction. Thus $\alpha/\bar{\alpha}$ is not a root of unity. Therefore

$$u_m = \frac{\alpha^m - \bar{\alpha}^m}{\alpha - \bar{\alpha}}$$

is a Lucas sequence. Since $\alpha\bar{\alpha} = y$, we note that $\alpha\bar{\alpha}$ is coprime to $2q$. Suppose that the term $u_n$ has a primitive divisor $\ell$. By definition, this is a prime $\ell$ dividing $u_n$ that does not divide $(\alpha - \bar{\alpha})^2 \cdot u_1 u_2 \cdots u_{n-1}$. However $\alpha = u + v \sqrt{-q}$ or $\alpha = (u + v \sqrt{-q})/2$ where $u, v \in \mathbb{Z}$. Thus $(\alpha - \bar{\alpha})^2 = -4q$ or $-q$, respectively. In particular $\ell \neq q$. It follows from (26) that $\ell = 2$. By Theorem 7 and the primality of $n$, we have $n = m_2$, the rank of apparition of $\ell = 2$ in the sequence $u_n$. Again by Theorem 7, $n = m_2 = 2$ or $3$ contradicting our assumption that $n \geq 5$. It follows that $u_n$ does not have a primitive divisor.

We now invoke the primitive divisor theorem (Theorem 6) to conclude that $n = 5$ or $7$ and that $(\alpha, \bar{\alpha})$ is equivalent to $((a - \sqrt{b})/2, (a + \sqrt{b})/2)$ where possibilities for $(a, b)$ are given by (24) if $n = 5$, and by (23) if $n = 7$. For illustration, we take $n = 5$ and $(a, b) = (12, -76)$. Thus $\alpha = (\pm 12 \pm \sqrt{-76})/2 = \pm 6 \pm \sqrt{-19}$, whence $q = 19$ and $y = \text{Norm}(\alpha) = 55$, quickly giving the solution in (62). The other possibilities for $(a, b)$ in (23) and (24) do not yield solutions to (61).

**Corollary 11.1.** The only solutions to (61) with $3 \leq q < 100$ and $n \geq 5$ prime correspond to the identities

$$22434^2 + 19 = 55^5, \quad 14^2 + 47 = 3^5 \quad \text{and} \quad 46^2 + 71 = 3^7.$$ 

**Proof.** Write $h_q$ for the class number of $M = \mathbb{Q}(\sqrt{-q})$. Thanks to Theorem 12, if $n \nmid h_q$ then the only corresponding solution is $22434^2 + 19 = 55^5$. Thus we may suppose that $n \mid h_q$. The only values of $q$ in our range with $h_q$ divisible by a prime $\geq 5$ are $q = 47, 71$ and 79, where $h_q = 5, 7$ and 5, respectively. We therefore reduce to considering the three cases $(q, n) = (47, 5), (71, 7)$ and $(79, 5)$, with $h_q = n$ in all three cases. From (61), we have

$$(x + q^k \sqrt{-q}) \cdot \mathcal{O}_M = \mathfrak{A}^n.$$ 

If $\mathfrak{A}$ is principal, then we are in the situation of the proof of Theorem 12 and we obtain a contradiction. Thus $\mathfrak{A}$ is not principal. Now for the three quadratic fields under consideration the class group is generated by the class $[\mathfrak{P}]$ where

$$\mathfrak{P} = 2 \cdot \mathcal{O}_M + \frac{(1 + \sqrt{-q})}{2} \cdot \mathcal{O}_M$$
is one of the two prime ideals dividing 2. We conclude that \([\mathfrak{A}] = [\mathfrak{B}]^{-r}\) for some \(1 \leq r \leq n - 1\). Observe that \(\mathfrak{C}\bar{\mathfrak{C}}\) is principal for any ideal \(\mathfrak{C}\) of \(\mathcal{O}_M\), so \([\mathfrak{C}] = [\mathfrak{C}]^{-1}\). We choose \(\mathfrak{B} = \mathfrak{A}\) or \(\mathfrak{A}\) so that \([\mathfrak{B}] = [\mathfrak{B}]^{-r}\) where \(1 \leq r \leq (n - 1)/2\). We note that

\[(x \pm q^k \sqrt{-q}) \cdot \mathcal{O}_M = \mathfrak{B}^n = (\mathfrak{B}^{-n})^r \cdot (\mathfrak{B}^r \mathfrak{B})^n,\]

where the ± sign is + if \(\mathfrak{B} = \mathfrak{A}\) and − if \(\mathfrak{B} = \mathfrak{A}\). We note that both \(\mathfrak{B}^{-n}\) and \(\mathfrak{B}^r \mathfrak{B}\) are principal. We find that \(\mathfrak{B}^{-n} = 2^{-n-1}(u + v\sqrt{-q}) \cdot \mathcal{O}_M\) where \(u, v\) are given by

\[(u, v) = \begin{cases} (-9, 1) & \text{if } q = 47, \\ (-21, 1) & \text{if } q = 71, \\ (7, 1) & \text{if } q = 79. \end{cases}\]

The ideal \(\mathfrak{B}^r \mathfrak{B}\) is integral as well as principal, and so has the form \((X' + Y' \sqrt{-q}) \cdot \mathcal{O}_M\) where \(X'\) and \(Y'\) are either both integers, or both halves of odd integers. We conclude that

\[2^{s+r^n+r}(x \pm q^k \sqrt{-q}) = (u + v\sqrt{-q})^r \cdot (X + Y \sqrt{-q})^n,\]

where \(X, Y \in \mathbb{Z}\) and \(s = 0\) or \(n\). Equating imaginary parts gives

\[G_r(X, Y) = \pm 2^{s+r^n+r}q^k,\]

where \(G_r \in \mathbb{Z}[X, Y]\) is a homogeneous polynomial of degree \(n\). We solved this Thue–Mahler equation using the Thue–Mahler solver associated to the paper [Gherga and Siksek 2022], for each of our three pairs \((q, n)\) and each \(0 \leq r \leq (n - 1)/2\). For illustration, we consider the case \(q = 47, n = 5, r = 2\). Thus \((u, v) = (-9, 1)\). We find

\[G_2(X, Y) = 2(-9X^5 + 85X^4Y + 4230X^3Y^2 - 7990X^2Y^3 - 99405XY^4 + 37553Y^5)\]

and are therefore led to solve the Thue–Mahler equation

\[-9X^5 + 85X^4Y + 4230X^3Y^2 - 7990X^2Y^3 - 99405XY^4 + 37553Y^5 = \pm 2^j q^k.\]

We find that the solutions are

\[(X, Y, j, k) = (1, 1, 16, 0) \quad \text{and} \quad (-1, -1, 16, 0),\]

and compute \(G_2(1, 1) = -2^{17}, G_2(-1, -1) = 2^{17}\). We note that \(17 = n + rn + r\); therefore \(s = n = 5\). We deduce that

\[x \pm 47^k \sqrt{-47} = \pm (-9 + \sqrt{-47})^2 \cdot (1 + \sqrt{-47})^5 = \pm (14 - \sqrt{-47}).\]

Thus \(x = \pm 14\) and \(k = 0\), giving the solution \(14^2 + 47 = 3^5\). The other cases are similar. □
12. The equation \( x^2 + (-1)^\delta q^{2k+1} = y^5 \)

We will soon apply Frey–Hellegouarch curves to study the equation \( x^2 + (-1)^\delta q^{2k+1} = y^n \) for prime exponents \( n \geq 7 \), and for \( q \) a prime in the range \( 3 \leq q < 100 \). In Section 2, we have solved this equation for \( n \in \{3, 4\} \). This leaves only the exponent \( n = 5 \) which we now treat through reduction to Thue–Mahler equations.

**Lemma 12.1.** Let \( 3 \leq q < 100 \) be a prime. The only solutions to the equation

\[
x^2 - q^{2k+1} = y^5, \quad x, y, k \text{ integers, } k \geq 0, \gcd(x, y) = 1,
\]

correspond to the identities

\[
\begin{align*}
2^2 - 3 &= 1^5, \\
2^2 - 5 &= (-1)^5, \\
10^2 - 7^3 &= (-3)^5, \\
56^2 - 11 &= 5^5, \\
16^2 - 13 &= 3^5, \\
4^2 - 17 &= (-1)^5, \\
7^2 - 17 &= 2^5, \\
6^2 - 37 &= (-1)^5, \\
3788^2 - 37 &= 27^5, \\
3^2 - 41 &= (-2)^5, \\
411^2 - 41^3 &= 10^5, \\
11^2 - 89 &= 2^5.
\end{align*}
\]

**Proof.** Let \( M = \mathbb{Q}(\sqrt{q}) \). For \( q \) in our range, the class number of \( M \) is 1, unless \( q = 79 \) in which case the class number is 3. Suppose first that \( y \) is odd. Then

\[
(x + q^k \sqrt{q}) \mathcal{O}_M = \mathfrak{A}^5,
\]

where \( \mathfrak{A} \) is an ideal of \( \mathcal{O}_M \). Since the class number is not divisible by 5, we see that \( \mathfrak{A} \) is principal and conclude that

\[
x + q^k \sqrt{q} = \epsilon^r \cdot \alpha^5,
\]

(64)

where \( \epsilon \) is some fixed choice of a fundamental unit for \( M \), \( -2 \leq r \leq 2 \), and \( \alpha \in \mathcal{O}_M \). Note that

\[
-x + q^k \sqrt{q} = \epsilon^{-r} \cdot \beta^5,
\]

where \( \beta \) is one of \( \pm \alpha \). Thus we may, without loss of generality, suppose that \( 0 \leq r \leq 2 \). The case \( r = 0 \) is easily shown not to lead to any solutions by following the approach in the proof of Theorem 12. Thus we suppose \( r = 1 \) or 2.

Let

\[
\theta = \begin{cases} \\
\sqrt{q} & \text{if } q \equiv 3 \pmod{4}, \\
(1 + \sqrt{q})/2 & \text{if } q \equiv 1 \pmod{4}.
\end{cases}
\]

Then \( \{1, \theta\} \) is a \( \mathbb{Z} \)-basis for \( \mathcal{O}_M \) and so we may write \( \alpha = X + Y \theta \) where \( X, Y \in \mathbb{Z} \). It follows that

\[
\epsilon^r \cdot \alpha^5 = F_r(X, Y) + G_r(X, Y) \theta,
\]

where \( F_r, G_r \) are homogeneous degree-5 polynomials in \( \mathbb{Z}[X, Y] \). Equating the coefficients of \( \theta \) in (64) yields the Thue–Mahler equations

\[
G_r(X, Y) = \begin{cases}
q^k & \text{if } q \equiv 3 \pmod{4}, \\
2q^k & \text{if } q \equiv 1 \pmod{4}.
\end{cases}
\]
Solving these equations for prime $3 \leq q < 100$ and for $r \in \{1, 2\}$ leads to the solutions given in the statement of the theorem with $y$ odd.

Next we consider the case when $y$ is even, so that $q \equiv 1 \pmod{8}$. The possible values of $q$ in our range are $17, 41, 73, 89$ and $97$ (where, in each case, $M$ has class number $1$). We can rewrite the equation $x^2 - q^{2k+1} = y^5$ as

$$
\left(\frac{x + q^k \sqrt{-q}}{2}\right)\left(\frac{x - q^k \sqrt{-q}}{2}\right) = 2^3 y_1^5,
$$

where $y_1 = y/2$. The two factors on the left-hand side are coprime. Let $\beta$ be a generator of

$$
\mathfrak{P} = 2\mathcal{O}_M + \left(\frac{1 + \sqrt{-q}}{2}\right) \cdot \mathcal{O}_M
$$

which is one of the two prime ideals above $2$. After possibly replacing $x$ by $-x$ we obtain

$$
\frac{x - q^k}{2} + q^k \theta = \frac{x + q^k \sqrt{-q}}{2} = \epsilon' \beta \alpha^5,
$$

where $-2 \leq r \leq 2$. Writing $\alpha = X + Y \theta$ and equating the coefficients of $\theta$ on both sides gives, for each choice of $q$ and $r$, a Thue–Mahler equation. Solving these leads to the solutions in the statement of the theorem with $y$ even.

\[\square\]

**Lemma 12.2.** Let $3 \leq q < 100$ be a prime. The only solutions to the equation

$$
x^2 + q^{2k+1} = y^5, \quad x, y, k \text{ integers, } k \geq 0, \gcd(x, y) = 1,
$$

correspond to the identities

\[5^2 + 7 = 2^5, \quad 181^2 + 7 = 8^5, \quad 22434^2 + 19 = 55^5, \quad 32 + 23 = 2^5, \quad 12 + 31 = 2^5 \text{ and } 14^2 + 47 = 3^5.\]

**Proof.** By Corollary 11.1 we know that the only solutions when $y$ is odd correspond to the identities $22434^2 + 19 = 55^5$ and $14^2 + 47 = 3^5$. Thus we may suppose $y$ is even, and write $y = 2y_1$. It follows that $q = 7, 23, 31, 47, 71, 79$. Let $M = \mathbb{Q} (\sqrt{-q})$. Let $\theta = (1 + \sqrt{-q})/2$, so that $1, \theta$ is a $\mathbb{Z}$-basis for $\mathcal{O}_M$. Observe that

$$
\left(\frac{x + q^k \sqrt{-q}}{2}\right)\left(\frac{x - q^k \sqrt{-q}}{2}\right) = 2^3 y_1^5,
$$

where the two factors on the left-hand side generate coprime ideals. Let

$$
\mathfrak{P} = 2\mathcal{O}_M + \theta \cdot \mathcal{O}_M;
$$

this is one of the two primes above $2$. Thus, after possibly changing the sign of $x$,

$$
\left(\frac{x + q^k \sqrt{-q}}{2}\right) \cdot \mathcal{O}_M = \mathfrak{P}^3 \cdot \mathfrak{A}^5
$$

for some ideal $\mathfrak{A}$ of $\mathcal{O}_M$. The class number of $\mathcal{O}_M$ is $1, 3, 3, 5, 7, 5$ according to whether $q = 7, 23, 31, 47, 71, 79$. In all cases the class group is cyclic and generated by $[\mathfrak{P}]$. If $q = 47$ or $79$ then the class
number is 5, and so \( \mathfrak{N}^5 \) is principal. Hence \( \mathfrak{P}^3 \) is principal which is a contradiction. Thus there are no solutions for \( q = 47 \) or 79. Let

\[
\mathfrak{c} = \begin{cases} 
1 \cdot \mathcal{O}_M, & q = 7, 23, 31, \\
\mathfrak{P}^2, & q = 71.
\end{cases}
\]

Note that \( \mathfrak{P}^3 \mathfrak{c}^{-5} \) is principal and we write \( \mathfrak{P}^3 \mathfrak{c}^{-5} = (u + v\theta) \cdot \mathcal{O}_M \). Thus

\[
\left( \frac{x + q^k \sqrt{-q}}{2} \right) \cdot \mathcal{O}_M = (u + v\theta) \cdot (\mathfrak{c} \mathfrak{I})^5.
\]

As the class number is coprime to 5, we see that \( \mathfrak{c} \mathfrak{I} \) is principal. Write \( \mathfrak{c} \mathfrak{I} = (X + Y\theta) \cdot \mathcal{O}_K \). After possibly changing the signs of \( X, Y \), we have

\[
\frac{x - q^k}{2} + q^k\theta = \frac{x + q^k \sqrt{-q}}{2} = (u + v\theta)(X + Y\theta)^5.
\]

Comparing the coefficients of \( \theta \) yields a degree-5 Thue–Mahler equation. Solving these Thue–Mahler equations as before gives the claimed solutions with \( y \) even.

\[\square\]

### 13. Frey–Hellegouarch curves for a ternary equation of signature \((n, n, 2)\)

In studying (7), we employed a factorization argument which reduced to (36) (which in turn we treated as a special case of a Fermat equation having signature \((n, n, n)\)). In the remainder of the paper, we are primarily interested in the equation \( x^2 + (-1)^\delta q^{2k+1} = y^n \), where \( q \) is a prime. We shall treat this, for prime \( n \geq 7 \), as a Fermat equation of signature \((n, n, 2)\) by rewriting this as \( y^n + q^{2k+1}(-1)^{(\delta+1)n} = x^2 \), a special case of

\[
y^n + q^\alpha z^n = x^2, \quad \gcd(x, y) = 1. \tag{65}
\]

Equation (65) has previously been studied by Ivorra and Kraus [2006], and by Bennett and Skinner [2004]. In this section, we recall some of these results and strengthen them slightly before specialising them to the case \( z = \pm 1 \) in forthcoming sections.

**Theorem 13** (Ivorra and Kraus). *Suppose that \( q \) is a prime with the property that \( q \) cannot be written in the form*

\[
q = |t^2 \pm 2^k|,
\]

*where \( t \) and \( k \) are integers, with \( k = 0, k = 3 \) or \( k \geq 7 \). Then there are no solutions to the Diophantine equation (65) in integers \( x, y, z, n \) and \( \alpha \) with \( n \) prime satisfying*

\[
n > (\sqrt{8(q + 1)} + 1)^2(q-1). \tag{66}
\]

To verify whether or not a given prime \( q \) can be written as \( |t^2 - 2^k| \), an old result of Bauer and Bennett [2002] can be helpful. We have, from Corollary 1.7 of [Bauer and Bennett 2002], if \( t \) and \( k \) are positive integers with \( k \geq 3 \) odd,

\[
|t^2 - 2^k| > 2^{13k/50}.
\]
Differences between perfect powers: prime power gaps

unless

(t, k) ∈ {(3, 3), (181, 15)}.  

In particular, a short computation reveals that Theorem 13 is applicable to the following primes \( q < 100 \):

\[
q \in \{11, 13, 19, 29, 43, 53, 59, 61, 67, 83\}.  
\]  

(67)

We shall make Theorem 13 more precise for these particular values of \( q \). To this end we attach to a solution of (65) a certain Frey–Hellegouarch curve, following the recipes of Bennett and Skinner. If \( yz \) is even in (65), then we define, assuming, without loss of generality, that \( x \equiv 1 (\text{mod} 4) \),

\[
F : Y^2 + XY = X^3 + \left(\frac{x-1}{4}\right)X^2 + \frac{y^n}{64}X, \quad \text{if } y \text{ is even},  
\]

and

\[
F : Y^2 + XY = X^3 + \left(\frac{x-1}{4}\right)X^2 + \frac{q^\alpha z^n}{64}X, \quad \text{if } z \text{ is even}.  
\]

If, on the other hand, \( yz \) is odd, we define

\[
F : Y^2 = X^3 + 2x X^2 + q^\alpha z^n X  
\]

or

\[
F : Y^2 = X^3 + 2x X^2 + y^n X,  
\]

depending on whether \( y \equiv 1 (\text{mod} 4) \) or \( y \equiv -1 (\text{mod} 4) \), respectively. Let

\[
\kappa = \begin{cases} 
1 & \text{if } yz \text{ is even}, \\
5 & \text{if } yz \text{ is odd}. 
\end{cases}  
\]

(71)

By the results of [Bennett and Skinner 2004], in each case, we may suppose that \( n \nmid \alpha \) and that the mod \( n \) representation of \( F \) arises from a newform \( f \) of weight 2 and level \( N = 2^\kappa \cdot q \). Let the \( q \)-expansion of \( f' \) be given by (37). As before, we denote the Hecke eigenfield by \( K_f = \mathbb{Q}(c_1, c_2, \ldots) \) and its ring of integers by \( \mathcal{O}_f \). In particular, there is a prime ideal \( n \) of \( \mathcal{O}_f \) such that (38) holds. Let \( \ell \nmid 2q \) be prime and

\[
T = \{a \in \mathbb{Z} \cap [-2\sqrt{\ell}, 2\sqrt{\ell}] : a \equiv 0 (\text{mod} 2)\}.  
\]

We write

\[
\mathcal{D}'_{f,\ell} = ((\ell + 1)^2 - c_\ell^2) \cdot \prod_{a \in T} (a - c_\ell),  
\]

and

\[
\mathcal{D}_{f,\ell} = \begin{cases} 
\ell \cdot \mathcal{D}'_{f,\ell} & \text{if } K_f \neq \mathbb{Q}, \\
\mathcal{D}'_{f,\ell} & \text{if } K_f = \mathbb{Q}. 
\end{cases}  
\]

Lemma 13.1. Let \( f \) be a newform of weight 2 and level \( N = 2^\kappa \cdot q \). Let \( \ell \nmid 2q \) be a prime. If \( \tilde{\rho}_{F,n} \sim \tilde{\rho}_{f,n} \), then \( n \mid \mathcal{D}_{f,\ell} \).

Proof. The proof is almost identical to the proof of Lemma 8.2. The only difference is the definition of \( T \) which takes into account the fact \( F \) has a single rational point of order 2 instead of full 2-torsion. \( \square \)
The following is a slight refinement of Theorem 1.3 of [Bennett and Skinner 2004].

**Proposition 13.2.** Suppose that $q$ belongs to (67). Then there are no solutions to (65) in integers $x$, $y$, $z$, $n$ and $\alpha$ with $\gcd(x, y) = 1$ and $n \geq 7$ prime, except, possibly, $n = 7$ and $q \in \{29, 43, 53, 59, 61\}$, or one of the following holds:

- $q = 11$, $n = 7$ and $yz \equiv 1 \pmod{2}$, or
- $q = 19$, $n = 7$ and $yz \equiv 1 \pmod{2}$, or
- $q = 43$, $n = 11$ and $yz \equiv 1 \pmod{2}$, or
- $q = 53$, $n = 17$ and $yz \equiv 1 \pmod{2}$, or
- $q = 59$, $n = 11$ and $yz \equiv 0 \pmod{2}$, or
- $q = 61$, $n = 13$ and $yz \equiv 1 \pmod{2}$, or
- $q = 67$, $n \in \{7, 11, 13, 17\}$ and $yz \equiv 1 \pmod{2}$, or
- $q = 83$, $n = 7$ and $yz \equiv 1 \pmod{2}$.

**Proof.** For a weight-2 newform $f$ of level $N$ and primes $\ell_1, \ldots, \ell_m$ (all coprime to $2q$), write $D_{f, \ell_1, \ldots, \ell_m}$ for the ideal of $O_f$ generated by $D_{f, \ell_1}, \ldots, D_{f, \ell_m}$. Let $B_{f, \ell_1, \ldots, \ell_m} \in \mathbb{Z}$ be the norm of the ideal $D_{f, \ell_1, \ldots, \ell_m}$. If $\tilde{\rho}_{f, n} \sim \tilde{\rho}_{f, \ell}$ then $n \mid D_{f, \ell_1, \ldots, \ell_m}$ by Lemma 13.1. Write $B_{f, \ell_1, \ldots, \ell_m} = \text{Norm}(D_{f, \ell_1, \ldots, \ell_m})$. Thus $n \mid B_{f, \ell_1, \ldots, \ell_m}$.

In our computations, we take $\ell_1, \ldots, \ell_m$ to be the primes $< 100$ coprime to $2q$, and we let $B_f = B_{f, \ell_1, \ldots, \ell_m}$.

If $B_f \neq 0$, then we certainly have a bound on $n$. If $B_f$ is divisible only by primes $\leq 5$, then we know that (38) does not hold for that particular $f$, and we can eliminate it from further consideration.

For primes $q$ in (67), we apply this with newforms $f$ of levels $N = 2^\kappa q$, $\kappa \in \{1, 5\}$. We obtain the desired conclusion that (65) has no solutions provided $n \geq 7$ is prime, unless $q \in \{29, 43, 53, 59, 61\}$ and $n = 7$, or $(q, n, \kappa)$ is one of

\[
(11, 7, 5), \quad (13, 7, 1), \quad (19, 7, 5), \quad (43, 11, 1), \quad (43, 11, 5), \quad (53, 17, 5), \quad (59, 11, 1), \quad (61, 31, 1), \quad (61, 13, 5), \quad (67, 17, 1), \quad (67, 7, 5), \quad (67, 11, 5), \quad (67, 13, 5), \quad (67, 17, 5), \quad (83, 7, 1), \quad (83, 7, 5).
\]

We show that the triples $(13, 7, 1), (43, 11, 1), (61, 31, 1), (67, 17, 1)$ and $(83, 7, 1)$ do not have corresponding solutions; the remaining triples lead to the noted possible exceptions. For illustration, take $q = 83$ and $\kappa = 1$, so that $N = 2 \times 83 = 166$. There are three conjugacy classes of weight-2 newforms of level $N$, which we denote by $f_1$, $f_2$, $f_3$, which respectively have Hecke eigenfields $\mathbb{Q}$, $\mathbb{Q}(\sqrt{5})$ and $\mathbb{Q}(\theta)$ where $\theta^3 - \theta^2 - 6\theta + 4 = 0$. We find

\[
B_{f_1} = 3^2 \times 5, \quad B_{f_2} = 5, \quad B_{f_3} = 7.
\]

We therefore deduce that $f = f_3$ and $n = 7$. In fact, $D_f = (7, 3 + \theta)$ is a prime ideal above 7, so we take $n = (7, 3 + \theta)$. A short calculation verifies the congruences in hypotheses (i) and (ii) of Theorem 8, whence $\ell + 1 \equiv c_\ell \pmod{n}$ for all $\ell$ with $\ell \parallel 2 \cdot 83$. It follows from Lemma 7.1 that

\[
a_\ell(F) \equiv c_\ell \pmod{n}
\]
for all primes $\ell$ of good reduction for $F$ and hence $7 \mid (\ell + 1 - a_\ell(F))$ for all such primes $\ell$ of good reduction. This now implies that $\bar{\rho}_{F,7}$ is reducible \cite{Serre1975}, IV-6, giving a contradiction.

We argue similarly for

$$ (q, n, \kappa) = (13, 7, 1), (43, 11, 1), (61, 31, 1), (67, 17, 1). $$

In each case, Lemma 13.1 eliminates all but one class of newforms which are then treated via Theorem 8. \qed

For other odd primes $q < 100$, outside the set (67), we can, in certain cases, still show that (65) has no nontrivial solutions for suitably large $n$, under the additional assumption that $yz \equiv 0 \pmod{2}$ or, for other $q$, under the assumption that $yz \equiv 1 \pmod{2}$. To be precise, we have the following two propositions.

**Proposition 13.3.** Suppose that $q \in \{3, 5, 37, 73\}$. Then there are no solutions to (65) in integers $x, y, z, n$ and $\alpha$ with $yz \equiv 0 \pmod{2}$, $\gcd(x, y) = 1$ and $n \geq 7$ prime, except, possibly, $(q, n) = (73, 7)$.

**Proposition 13.4.** Suppose that $q \in \{23, 31, 47, 71, 79, 97\}$. Then there are no solutions to (65) in integers $x, y, z, n$ and $\alpha$ with $yz \equiv 1 \pmod{2}$, $\gcd(x, y) = 1$ and $n \geq 7$ prime, except, possibly, $n = 7$ and $q \in \{23, 31, 47, 71, 97\}$, or $(q, n) = (79, 11)$, or $(q, n) = (97, 29)$.

As in the case of Proposition 13.2, these results follow after a small amount of computation, by applying Lemma 13.1 and Theorem 8.

### 14. The equation $x^2 \pm q^{2k+1} = y^n$ and proofs of Theorems 2 and 3

We now specialize and improve on the results of Section 13, proving the following.

**Proposition 14.1.** Let $(x, y, k)$ be a solution to the equation

$$ x^2 + (-1)^\delta q^{2k+1} = y^n, \quad \delta \in \{0, 1\}, \quad k \geq 0, \quad \gcd(x, y) = 1, \quad (72) $$

where $q$ is a prime in the range $3 \leq q < 100$, and $n \geq 7$ is prime. Suppose, in addition, that

(a) if $y$ is odd then $\delta = 1$;

(b) if $\delta = 1$ then $q \notin \{3, 5, 17, 37\}$.

If $y$ is even, suppose, without loss of generality, that $x \equiv 1 \pmod{4}$. Write

$$ \kappa = \begin{cases} 1 & \text{if } y \text{ is even}, \\ 5 & \text{if } y \text{ is odd}. \end{cases} \quad (73) $$

Let $v \in \{0, 1\}$ satisfy $k \equiv v \pmod{2}$. Attach to the solution $(x, y, k)$ the Frey–Hellegouarch curve $G = G_{x,k}$:

$$ G = G_{x,k} : \begin{cases} Y^2 = X^3 + 4X^2 + 4(x^2 + (-1)^\delta q^{2k+1})X & \text{if } \kappa = 1, \\ Y^2 = X^3 - 4X^2 + 4(x^2 + (-1)^\delta q^{2k+1})X & \text{if } \kappa = 5 \text{ and } q \equiv (-1)^\delta \pmod{4}, \\ Y^2 = X^3 + 2X^2 + (x^2 + (-1)^\delta q^{2k+1})X & \text{if } \kappa = 5 \text{ and } q \equiv (-1)^{\delta+1} \pmod{4}. \end{cases} $$
Table 3. Data for Proposition 14.1. Here the elliptic curves $E$ are given by their Cremona labels.

\[
\begin{array}{cccc}
q & \delta & \kappa & v \\
7 & 0 & 1 & 0 & \text{14a1} \\
7 & 0 & 1 & 1 & \text{14a1} \\
23 & 0 & 1 & 0 & \text{46a1} \\
31 & 0 & 1 & 0 & \text{62a1} \\
31 & 0 & 1 & 1 & \text{62a1} \\
41 & 1 & 1 & 0 & \text{82a1} \\
41 & 1 & 5 & 0 & \text{1312a1, 1312b1} \\
41 & 1 & 5 & 1 & \text{1312a1, 1312b1} \\
\end{array}
\]

Table 3. Data for Proposition 14.1. Here the elliptic curves $E$ are given by their Cremona labels.

Then either $n > 1000$ and $\bar{\rho}_{G,n} \sim \bar{\rho}_{E,n}$ where $E/\mathbb{Q}$ is an elliptic curve of conductor $2^\kappa q$ given in Table 3 or the solution $(x, y, k)$ corresponds to one of the identities

\[
\begin{align*}
11^2 + 7 &= 2^7, \\
45^2 + 23 &= 2^{11}, \\
13^2 - 41 &= 2^7, \\
9^2 + 47 &= 2^7, \\
7^2 + 79 &= 2^7, \\
91^2 - 89 &= 2^{13}, \\
15^2 - 97 &= 2^7.
\end{align*}
\]

Before proving this result, we make a few remarks on the assumptions in Proposition 14.1. Our eventual goal is to prove Theorems 1, 2 and 3, and thus we are interested in the equation $x^2 + (-1)\delta q^\alpha = y^n$ where $3 \leq q < 100$. Theorems 4 and 5 (proved in Sections 5 and 10, respectively) treat the case where $\alpha$ is even, so we are reduced to $\alpha = 2k + 1$. The results of Section 2, Corollary 11.1 and Lemmas 12.1, 12.2 allow us to restrict the exponent $n$ to be a prime $\geq 7$. Thanks to Theorem 12, we need not consider the case where $\delta = 0$ and $y$ is odd, which explains the reason for assumption (a). With a view to proving the proposition, we will soon provide a method which is usually capable, for a fixed $q$, $\delta$ and $n$, of showing that (72) does not have a solution. If $\delta = 1$, and $q$ is one of the values $3, 5, 17$ or $37$, then there is a solution to (72) for all odd values of the exponent $n$: $2^2 - 3 = 1^n, \quad 2^2 - 5 = (-1)^n, \quad 4^2 - 17 = (-1)^n, \quad 6^2 - 37 = (-1)^n$; and so our method fails if $\delta = 1$ and $q$ is one of these four values. This explains assumption (b) in the statement of the proposition.

We note that (72) is a special case of (65) with $z$ specialised to the value $(-1)^{\delta+1}$, and with $\alpha = 2k + 1$. The value $\kappa$ in the statement of the proposition agrees with value for $\kappa$ in (71) given in the previous section. We note that if $y$ is odd, then $y \equiv (-1)^\delta \cdot q \pmod{4}$. The Frey–Hellegouarch curve $G$ is, up to isogeny, the same as the Frey–Hellegouarch curve $F$ in the previous section, but is more convenient for our purposes. More precisely, the model $G$ is isomorphic to $F$ given in (68) if $y$ even (i.e., $\kappa = 1$), and to $F$ given in (70) if $y \equiv 3 \pmod{4}$ (i.e., $\kappa = 5$ and $q \equiv (-1)^{\delta+1} \pmod{4}$). It is 2-isogenous to $F$ in (69) if $y \equiv 1 \pmod{4}$ (i.e., $\kappa = 5$ and $q \equiv (-1)^\delta \pmod{4}$). Thus $\bar{\rho}_{F,n} \sim \bar{\rho}_{G,n}$ in all three cases. We conclude from the previous section that $\bar{\rho}_{G,n} \sim \bar{\rho}_{f,n}$ where $f$ is a weight-2 newform of level $N = 2^\kappa q$. 

\[
\begin{array}{cccc}
q & \delta & \kappa & v \\
47 & 0 & 1 & 0 & \text{94a1} \\
71 & 0 & 1 & 0 & \text{142c1} \\
71 & 0 & 1 & 1 & \text{142c1} \\
73 & 1 & 5 & 0 & \text{2336a1, 2336b1} \\
73 & 1 & 5 & 1 & \text{2336a1, 2336b1} \\
79 & 0 & 1 & 0 & \text{158e1} \\
89 & 1 & 1 & 0 & \text{178b1} \\
97 & 1 & 1 & 0 & \text{194a1}
\end{array}
\]
Note that if \( \kappa = 1 \) (that is, \( y \) is even) then \( 1 + (-1)^\delta q \equiv 0 \pmod{8} \). This together with the assumptions of Proposition 14.1 shows that we are concerned with 30 possibilities for the triple \((q, \delta, \kappa)\), namely
\[
(7, 0, 1), (7, 1, 5), (11, 1, 5), (13, 1, 5), (19, 1, 5), (23, 0, 1), (23, 1, 5), (29, 1, 5), \\
(31, 0, 1), (31, 1, 5), (41, 1, 1), (41, 1, 5), (43, 1, 5), (47, 0, 1), (47, 1, 5), (53, 1, 5), \\
(59, 1, 5), (61, 1, 5), (67, 1, 5), (71, 0, 1), (71, 1, 5), (73, 1, 1), (73, 1, 5), (79, 0, 1), \\
(79, 1, 5), (83, 1, 5), (89, 1, 1), (89, 1, 5), (97, 1, 1), (97, 1, 5).
\]

Bounding the exponent \( n \). In the previous section we defined an ideal \( \mathcal{D}_{f, \ell_1, \ldots, \ell_r} \) which if nonzero allows us to bound the exponent \( n \) in (65). That bound will also be valid for (72) since it is a special case of (65). We now offer a refinement that is often capable of yielding a better bound for (72).

Fix a triple \((q, \delta, \kappa)\) from the above list. We also fix \( v \in \{0, 1\} \) and suppose that \( k \equiv v \pmod{2} \). Let \( f \) be a weight-2 newform of level \( N = 2^\kappa q \) with q-expansion as in (37). Write \( K_f \) for the Hecke eigenfield of \( f \), and \( \mathcal{O}_f \) for the ring of integers of \( K_f \). For a prime \( \ell \neq 2, q \), define
\[
S_\ell = \{ a_\ell(G_{w,v}) : w \in \mathbb{F}_\ell, w^2 + (-1)^\delta q^{2^{v+1}} \not\equiv 0 \pmod{\ell} \}.
\]

Let
\[
\mathcal{T} = \mathcal{T}_\ell = \begin{cases} 
S_\ell \cup \{ \ell + 1, -\ell - 1 \} & \text{if } (-1)^{\delta+1} q \text{ is a square modulo } \ell, \\
S_\ell & \text{otherwise}.
\end{cases}
\]

Let
\[
\mathcal{E}_\ell' = \prod_{a \in \mathcal{T}} (a - c_\ell) \quad \text{and} \quad \mathcal{E}_\ell = \begin{cases} 
\ell \cdot \mathcal{E}_\ell' & \text{if } K_f \neq \mathbb{Q}, \\
\mathcal{E}_\ell' & \text{if } K_f = \mathbb{Q},
\end{cases}
\]

where, as before, \( c_\ell \) is the \( \ell \)-th coefficient in the q-expansion of \( f \).

**Lemma 14.2.** Let \( n \) be a prime ideal of \( \mathcal{O}_f \) above \( n \). If \( \tilde{\rho}_{G,n} \sim \tilde{\rho}_{f,n} \) then \( n \mid \mathcal{E}_\ell \).

**Proof.** Write \( k = 2u + v \) with \( u \in \mathbb{Z} \). Let \( w \in \mathbb{F}_\ell \) satisfy \( w \equiv x/q^{2u} \pmod{\ell} \). Hence
\[
y^n = x^2 + (-1)^\delta q^{2k+1} \equiv q^{4u} \cdot (w^2 + (-1)^\delta q^{2^{v+1}}) \pmod{\ell}.
\]

It follows that \( \ell \mid y \) if and only if \( w^2 + (-1)^\delta q^{2^{v+1}} \pmod{\ell} \). Suppose first that \( \ell \nmid y \). The elliptic curves \( G_{x,k}/\mathbb{F}_\ell \) and \( G_{w,v}/\mathbb{F}_\ell \) are isomorphic, and so \( a_\ell(G_{x,k}) = a_\ell(G_{w,v}) \). In particular, \( a_\ell(G_{x,k}) \in \mathcal{T}_\ell \) and so \( a_\ell(G_{x,k}) - c_\ell \) divides \( \mathcal{E}_\ell \). Likewise, if \( \ell \mid y \) (which can only happen if \( (-1)^{\delta+1} q \) is a square modulo \( \ell \)) then \( (\ell + 1)^2 - c_\ell^2 \) divides \( \mathcal{E}_\ell \). The lemma follows from Lemma 7.1. \( \square \)

**A sieve.** Lemma 14.2 will soon allow us to eliminate most possibilities for the newform \( f \) in a manner similar to Propositions 13.2, 13.3 and 13.4. We will still need to treat some cases for fixed exponent \( n \). To this end, we will employ a sieving technique similar to the one in Section 10.

Fix a prime \( n \geq 7 \), and let \( n \) be a prime ideal of \( \mathcal{O}_f \) above \( n \). Let \( \ell \neq q \) be a prime. Suppose
\begin{enumerate}[(i)]
\item \( \ell = tn + 1 \) for some positive integer \( t \);
\item either \( n \nmid (4 - c_\ell^2) \), or \( (-1)^{\delta+1} q \) is not a square modulo \( \ell \).
\end{enumerate}
Let
\[ A = \{ m \in \{0, 1, \ldots, 2n - 1\} : m \equiv v \pmod{2}, n \nmid (2m + 1) \}, \]
\[ \mathcal{X}_\ell = \{(z, m) \in \mathbb{F}_\ell \times A : (z^2 + (-1)^\delta q^{2m+1})^t \equiv 1 \pmod{\ell}\}, \]
\[ \mathcal{Y}_\ell = \{(z, m) \in \mathcal{X}_\ell : a_\ell(G_{z,m}) \equiv c_\ell \pmod{n}\}, \]
\[ \mathcal{Z}_\ell = \{m: \text{there exists } z \text{ such that } (z, m) \in \mathcal{Y}_\ell\}. \]

**Lemma 14.3.** Let \( \ell_1, \ldots, \ell_r \) be primes \( \neq q \) satisfying (i), (ii). Let
\[ \mathcal{Z}_{\ell_1,\ldots,\ell_r} = \bigcap_{i=1}^r \mathcal{Z}_{\ell_i}. \]
If \( \tilde{\rho}_{G,n} \sim \tilde{\rho}_{f,n} \) then
\[ (k \pmod{2n}) \in \mathcal{Z}_{\ell_1,\ldots,\ell_r}. \]

**Proof.** Let \( m \) be the unique element of \( \{0, 1, \ldots, 2n - 1\} \) satisfying \( k \equiv m \pmod{2n} \). Let \( \ell \neq q \) be a prime satisfying (i) and (ii). It is sufficient to show that \( m \in \mathcal{Z}_\ell \). First we will demonstrate that \( \ell \nmid y \). If \((-1)^{\delta+1} q \) is not a square modulo \( \ell \) then \( \ell \nmid y \) from (72). Otherwise, by (ii), \( n \nmid (4 - c_\ell^2) \). However, from (i) and the fact that \( n \mid n \) we have \( \ell + 1 \equiv 2 \pmod{n} \) and so \( n \nmid ((\ell + 1)^2 - c_\ell^2) \). It follows from Lemma 7.1 that \( \ell \) is a prime of good reduction for \( G_{x,k} \) and so \( \ell \nmid y \). We deduce from Lemma 7.1 that \( a_\ell(G_{x,k}) \equiv c_\ell \pmod{n} \).

In the previous section, we observed that \( n \nmid \alpha \) in (65) thanks to the results of [Bennett and Skinner 2004], whence \( n \nmid (2k + 1) \). Since \( k \equiv v \pmod{2} \), we know that \( m \in A \). Write \( k = 2nb + m \) with \( b \) a nonnegative integer and let \( z \in \mathbb{F}_\ell \) satisfy \( z \equiv x/q^{2nb} \pmod{\ell} \). Then
\[ z^2 + (-1)^\delta q^{2m+1} \equiv \frac{1}{q^{4nb}}(x^2 + (-1)^\delta q^{2k+1}) \equiv \left(\frac{y}{q^{4b}}\right)^n \pmod{\ell}. \]

From (i), we deduce that
\[ (z^2 + (-1)^\delta q^{2m+1})^t \equiv \left(\frac{y}{q^{4b}}\right)^t \equiv 1 \pmod{\ell}. \]
Thus \( (z, m) \in \mathcal{X}_\ell \). Moreover, we have that \( G_{x,k}/\mathbb{F}_\ell \) and \( G_{z,m}/\mathbb{F}_\ell \) are isomorphic elliptic curves, whence \( a_\ell(G_{z,m}) = a_\ell(G_{x,k}) \equiv c_\ell \pmod{n} \). Thus \( (z, m) \in \mathcal{Y}_\ell \) and so \( m \in \mathcal{Z}_\ell \) as required. \( \square \)

**Remarks.** We would like to explain how to compute \( \mathcal{Z}_\ell \) efficiently, given \( n \) and \( \ell \).

1. In our computations, the value \( t \) will be relatively small compared to \( n \) and to \( \ell = tn + 1 \). Let \( g \) be a primitive root modulo \( \ell \) (that is, a cyclic generator for \( \mathbb{F}_\ell^\times \)), and let \( h = g^n \). The set \( \mathcal{X}_\ell \) consists of pairs \( (z, m) \in \mathbb{F}_\ell \times A \) such that \( (z^2 + (-1)^\delta q^m)^t \equiv 1 \pmod{\ell} \). Hence \( z^2 + (-1)^\delta q^m \) is one of the values \( 1, h, h^2, \ldots, h^{t-1} \). Thus, to compute \( \mathcal{X}_\ell \), we run through \( i = 0, 1, \ldots, t - 1 \) and \( m \in A \) and solve \( z^2 = h^i - (-1)^\delta q^m \). We note that the expected cardinality of \( \mathcal{X}_\ell \) should be roughly \( t \times \#A \approx t \times n \approx \ell \).

2. It seems at first that, in order to compute \( \mathcal{Y}_\ell \) and \( \mathcal{Z}_\ell \), we need to compute \( a_\ell(G_{z,m}) \) for all \( (z, m) \in \mathcal{X}_\ell \), and this might be an issue for large \( \ell \). There is in fact a shortcut that often means that we only need to
perform a few of these computations. In fact we will need to compute \( Z_\ell \) for large values of \( \ell \) only for rational newforms \( f \) that correspond to elliptic curves \( E/\mathbb{Q} \) with nontrivial 2-torsion. In this case, we note that \( a_\ell(G_{z,m}) \equiv a_\ell(E) \pmod{2} \), as both elliptic curves have nontrivial 2-torsion. If \( (z, m) \in \mathcal{Y}_\ell \), then \( a_\ell(G_{z,m}) \equiv a_\ell(E) \pmod{2n} \). However, by the Hasse–Weil bounds,

\[
|a_\ell(G_{z,m}) - a_\ell(E)| \leq 4\sqrt{\ell}.
\]

Suppose, in addition, that \( n^2 > 4\ell \) (which will be usually satisfied as \( t \) is typically small). Then, the congruence \( a_\ell(G_{z,m}) \equiv c_\ell = a_\ell(E) \pmod{2n} \) is equivalent to the equality \( a_\ell(G_{z,m}) = a_\ell(E) \), and so to \( \#G_{z,m}(\mathbb{F}_\ell) = \#E(\mathbb{F}_\ell) \). To check whether the equality \( \#G_{z,m}(\mathbb{F}_\ell) = \#E(\mathbb{F}_\ell) \) holds for a particular pair \( (z, m) \in \mathcal{X}_\ell \), we first choose a random point \( Q \in G_{z,m}(\mathbb{F}_\ell) \) and check whether \( \#E(\mathbb{F}_\ell) \cdot Q = 0 \). Only for pairs \( (z, m) \in \mathcal{X}_\ell \) that pass this test do we need to compute \( a_\ell(G_{z,m}) \) and check the congruence \( a_\ell(G_{z,m}) \equiv a_\ell(E) \pmod{n} \).

**A refined sieve.** We note that if \( \mathcal{Z}_{\ell_1,...,\ell_r} = \emptyset \) then \( \tilde{\rho}_{G,n} \sim \tilde{\rho}_{f,n} \). In our computations, described later, we are always able to find suitable primes \( \ell_1, \ldots, \ell_r \) satisfying (i), (ii), so that \( \mathcal{Z}_{\ell_1,...,\ell_r} = \emptyset \), at least for \( n \) suitably large. For smaller values of \( n \) (say less than 50), we occasionally failed. We now describe a refined sieving method that, whilst being somewhat slow, has a better chance of succeeding for those smaller values of the exponent \( n \).

Let \( (q, \delta, \kappa) \) be one of our 30 triples given in (74), and let \( n \geq 7 \) be a prime. Suppose that \( (x, y, k) \) is a solution to (72) where \( y \) is even if and only if \( \kappa = 1 \). Let \( \phi = \sqrt{(-1)^{\delta+1}q} \) and set \( M = \mathbb{Q}(\phi) \). Let \( \mathfrak{P} \) be one of the prime ideals of \( \mathcal{O}_M \) above 2.

Our first goal is to produce a finite set \( \mathcal{S} \subset M^* \), such that

\[
x + q^k \phi = \gamma \cdot \alpha^n
\]

for some \( \gamma \in \mathcal{S} \) and \( \alpha \in \mathcal{O}_M \). This is the objective of Lemmata 14.4 and 14.5. Both of these make an additional assumption on the class group, but this assumption will in fact be satisfied in all cases where we need to apply our refined sieve.

**Lemma 14.4.** Let \( \kappa = 5 \). Suppose that the class group \( \text{Cl}(\mathcal{O}_M) \) of \( \mathcal{O}_M \) is cyclic and generated by the class \( [\mathfrak{P}] \). Let \( h = \#\text{Cl}(\mathcal{O}_M) \) and set

\[
\mathcal{I} = \{ 0 \leq i \leq h - 1 : \mathfrak{P}^{-ni} \text{ is principal} \}.
\]

Choose for each \( i \in \mathcal{I} \) a generator \( \beta_i \) for \( \mathfrak{P}^{-ni} \). Let \( \epsilon \) be a fundamental unit for \( M \) (recall that if \( \kappa = 5 \) then \( \delta = 1 \) and so \( M \) is real). Let

\[
\mathcal{S} = \left\{ \epsilon^j \beta_i : -\frac{n-1}{2} \leq j \leq \frac{n-1}{2}, i \in \mathcal{I} \right\}.
\]

Then there is some \( \gamma \in \mathcal{S} \) and \( \alpha \in \mathcal{O}_M \) such that (75) holds. Also, \( \text{Norm}(\alpha) = 2^\mu y \) for some \( \mu \geq 0 \).

**Proof.** As \( \kappa = 5 \), we have that \( y \) is odd. Then

\[
(x + q^k \phi)\mathcal{O}_M = \mathfrak{A}^n.
\]
where $\mathfrak{A}$ is an ideal of $\mathcal{O}_M$ with norm $y$. Since $[\mathfrak{P}]$ generates the class group, the same is true of $[\mathfrak{P}]^{-1}$. Hence $[\mathfrak{A}] = [\mathfrak{P}]^{-i}$ for some $i \in \{0, 1, \ldots, h - 1\}$. Now

$$(x + q^k \theta)\mathcal{O}_M = \mathfrak{P}^{-ni} \cdot (\mathfrak{P}^i \cdot \mathfrak{A})^n.$$  

Since $\mathfrak{P}^i \cdot \mathfrak{A}$ is principal, it follows that $\mathfrak{P}^{-ni}$ is also principal. The lemma follows.

**Lemma 14.5.** Let $\kappa = 1$. Suppose that the class group $\text{Cl}(\mathcal{O}_M)$ of $\mathcal{O}_M$ is cyclic and generated by the class $[\mathfrak{P}]$. Let $h = \# \text{Cl}(\mathcal{O}_M)$ and set

$$\mathcal{I} = \{0 \leq i \leq h - 1 : \mathfrak{P}^{n(1-i)-2} \text{ is principal}\}.$$  

Choose for each $i \in \mathcal{I}$ a generator $\beta_i$ for $\mathfrak{P}^{n(1-i)-2}$. Let

$$S' = \{\beta_i : i \in \mathcal{I}\} \cup \{\beta_i : i \in \mathcal{I}\},$$

where $\bar{\beta_i}$ denotes the Galois conjugate of $\beta_i$. Let

$$S = \begin{cases} 
\{2 \cdot \beta : \beta \in S'\} & \text{if } \delta = 0, \\
\{2 \cdot \epsilon^j \beta : -(n - 1)/2 \leq j \leq (n - 1)/2, \beta \in S'\} & \text{if } \delta = 1,
\end{cases}$$  

where $\epsilon$ is a fundamental unit for $M$. Then there is some $\gamma \in S$ and $\alpha \in \mathcal{O}_M$ such that (75) holds. Also, $\text{Norm}(\alpha) = 2^\mu y$ for some $\mu \in \mathbb{Z}$.  

**Proof.** As $\kappa = 1$, we have that $y$ is even. Then

$$\left(\frac{x + q^k \phi}{2}\right)\mathcal{O}_M = \mathfrak{C}^{n-2} \mathfrak{A}^n,$$

where $\mathfrak{A}$ is an ideal of $\mathcal{O}_M$ with norm $y/2$ and $\mathfrak{C}$ is one of $\mathfrak{P}$. $\bar{\mathfrak{P}}$. Since $[\mathfrak{P}]$ generates the class group so does $[\mathfrak{C}]^{-1}$. Hence $[\mathfrak{A}] = [\mathfrak{C}]^{-i}$ for some $i \in \{0, 1, \ldots, h - 1\}$. Now

$$\left(\frac{x + q^k \phi}{2}\right)\mathcal{O}_M = \mathfrak{C}^{n(1-i)-2} \cdot (\mathfrak{C}^i \mathfrak{A})^n.$$  

But $\mathfrak{C}^i \cdot \mathfrak{A}$ is principal, whence $\mathfrak{C}^{n(1-i)-2}$ is principal, and so $i \in \mathcal{I}$ and $\mathfrak{C}^{n(1-i)-2}$ is generated by either $\beta_i$ or $\bar{\beta_i}$. The lemma follows.  

We will now describe our refined sieve. Fix $m \in \{0, 1, \ldots, 2n\}$ and suppose $k \equiv m \pmod{2n}$. Let $n$ be a prime ideal of $\mathcal{O}_f$ above $n$. Let $\ell \neq q$ be a prime. Suppose

(a) $\ell = tn + 1$ for some positive integer $t$;  
(b) $n \nmid (4 - c_\ell^2)$;  
(c) $(-1)^{\delta+1}q$ is a square modulo $\ell$.  

We choose an integer $s$ such that $s^2 \equiv (-1)^{\delta+1} q \pmod{\ell}$. Let

$$\mathfrak{L} = \ell \mathcal{O}_M + (s - \phi)\mathcal{O}_M.$$
By the Dedekind–Kummer theorem $\ell$ splits in $O_M$ and $L$ is one of the two prime ideals above $\ell$. In particular, $O_M/L \cong \mathbb{F}_\ell$ and $\phi \equiv s \pmod{L}$. Let
\[
\mathcal{X}_{\ell,m} = \{z \in \mathbb{F}_\ell : (z^2 + (-1)^{s}q^{2m+1})^t \equiv 1 \pmod{\ell}\},
\]
\[
\mathcal{Y}_{\ell,m} = \{z \in \mathcal{X}_{\ell,m} : a_\ell(G_{z,m}) \equiv c_\ell \pmod{n}\},
\]
\[
\mathcal{U}_{\ell,m} = \{(z, \gamma) : z \in \mathcal{Y}_{\ell,m}, \gamma \in S, (z + q^m \phi)^t \equiv \gamma^t \pmod{\mathcal{L}}\},
\]
\[
\mathcal{W}_{\ell,m} = \{\gamma : \text{there exists } z \text{ such that } (z, \gamma) \in \mathcal{U}_{\ell,m}\}.
\]

**Lemma 14.6.** Let $\ell_1, \ldots, \ell_r$ be primes $\neq q$ satisfying (a), (b) and (c) above. Let
\[
\mathcal{W} = \mathcal{W}_{\ell_1, \ldots, \ell_r} = \bigcap_{i=1}^r \mathcal{W}_{\ell_i}.
\]
If $\bar{\rho}_{G,n} \sim \bar{\rho}_{f,n}$, then there is some $\gamma \in \mathcal{W}$ and some $\alpha \in O_M$ such that (75) holds.

**Proof.** Suppose $\ell$ satisfies conditions (a), (b) and (c). As $\ell$ satisfies (a) and (b), it also satisfies hypotheses (i) and (ii) preceding the statement of Lemma 14.3. Write $k = 2nb + m$ where $b$ is a nonnegative integer, and let $z \equiv x/q^{2nb} \pmod{\ell}$. It follows from the proof of Lemma 14.3 that $\ell \nmid y$ and that $z \in \mathcal{Y}_{\ell,m}$. We know from Lemmata 14.4 and 14.5 that there is some $\gamma \in S$ such that $x + q^k \phi = \gamma \alpha^n$ where $\alpha \in O_M$ satisfies $\text{Norm}(\alpha) = 2^\mu y$ for some $\mu \in \mathbb{Z}$. Note that $\gamma$ is supported only on the prime ideals above 2. Since $L | \ell$, we have $\text{ord}_L(\alpha) = \text{ord}_L(\gamma) = 0$. Hence
\[
z + q^m \phi \equiv \frac{1}{q^{2nb}}(x + q^k \phi) \equiv \gamma \cdot \left(\frac{\alpha}{q^{2b}}\right)^n \pmod{\mathcal{L}}.
\]
Since $(O_M/L)^* \cong \mathbb{F}_\ell^*$ is cyclic of order $\ell - 1 = tn$, we have
\[
(z + q^m \phi)^t \equiv \gamma^t \pmod{\mathcal{L}}.
\]
Thus $(z, \gamma) \in \mathcal{U}_{\ell,m}$ and hence $\gamma \in \mathcal{W}_{\ell,m}$. The lemma follows. \(\square\)

**Proof of Proposition 14.1.** Our proof of Proposition 14.1 is the result of applying Magma scripts based on Lemmata 14.2, 14.3 and 14.6, as well as solving a few Thue–Mahler equations. Our approach subdivides the proof into 60 cases corresponding to 60 quadruples $(q, \delta, \kappa, v)$: here $(q, \delta, \kappa)$ is one of the 30 triples in (74), and $v \in \{0, 1\}$. Let $(x, y, k)$ be a solution to (72) with prime exponent $n \geq 7$. Suppose that $y$ is even if $\kappa = 1$ and $y$ is odd if $\kappa = 5$. Suppose, in addition, that $k \equiv v \pmod{2}$. Our first step is to compute the newforms $f$ of weight 2 and level $N = 2^k q$. We know that for one these newforms $f$, we have $\bar{\rho}_{G,n} \sim \bar{\rho}_{f,n}$ where $G = G_{x,k}$ is the Frey–Hellegouarch curve given in Proposition 14.1, and $n | n$ is a prime ideal of $O_f$, the ring of integers of the Hecke eigenfield $K_f$. Let $p_1, \ldots, p_s$ be the primes $\leq 200$ distinct from 2 and $q$, and let
\[
\mathcal{E}_f = \sum_{i=1}^s \mathcal{E}_{p_i}.
\]
where $\mathcal{E}_p$, is as in Lemma 14.2. It follows from Lemma 14.2 that if $\tilde{\rho}_{G,n} \sim \tilde{\rho}_{f,n}$ then $n \mid \mathcal{E}_f$, and so $n \mid \text{Norm}(\mathcal{E}_f)$.

We illustrate this by taking $(q, \delta, \kappa, v) = (31, 1, 5, 0)$. There are 8 newforms $f_1, \ldots, f_8$ of weight 2 and level $2^k q = 992$, which all happen to be irrational. We find that

$$\text{Norm}(\mathcal{E}_f) = 7, 7, 210, 210, 23, 23, 26 \times 3^2, 26 \times 3^2,$$

respectively for $j = 1, 2, \ldots, 8$. Thus $n = 7$ and $f = f_1$ or $f_2$. We consider first

$$f = f_1 = q + \sqrt{2}q^3 - q^5 - (1 + \sqrt{2})q^7 - q^9 + 2(1 - \sqrt{2})q^{11} + \cdots,$$

with Hecke eigenfield $K_f = \mathbb{Q}(\sqrt{2})$ having ring of integers $\mathcal{O}_f = \mathbb{Z}[\sqrt{2}]$. We found that $\mathcal{E}_f = (1 + 2\sqrt{2})$ which is one of the two prime ideals above 7. Hence $n = (1 + 2\sqrt{2})$. Next we compute $\mathcal{Z} = \mathbb{Z}_{\ell_1, \ldots, \ell_{30}}$ as in Lemma 14.3 where $\ell_1, \ldots, \ell_{30} \neq 31$ are the 30 primes satisfying (i) and (ii) with $t \leq 200$. We find that $\mathcal{Z} = \{0, 8\}$. Thus, by Lemma 14.3, we have $k \equiv 0$ or 8 (mod 14). Now for $m = 0$ and $m = 8$, we compute $\mathcal{W} = \mathcal{W}_{\ell_1, \ldots, \ell_{36}}$ as in Lemma 14.6, where $\ell_1, \ldots, \ell_{36} \neq 31$ are the 36 primes satisfying (a), (b) and (c) with $t \leq 800$. We found that $\mathcal{W} = \emptyset$ for $m = 0$ and that $\mathcal{W} = \{\epsilon^3\}$ for $m = 8$ where $\epsilon = 1520 + 273\sqrt{31}$, the fundamental unit of $M = \mathbb{Q}(\sqrt{31})$. Hence we conclude, by Lemma 14.6, that $k \equiv 8$ (mod 14) and that

$$x + 31^k \sqrt{31} = (1520 + 273\sqrt{31})^3 (X + Y \sqrt{31})^7,$$

for some integers $X, Y$. Equating the coefficients of $\sqrt{31}$ on both sides results in a degree-7 Thue–Mahler equation with huge coefficients. However, using an algorithm of Stoll and Cremona [2003] for reducing binary forms we discover that this Thue–Mahler equation can be rewritten as

$$31^k = -56U^7 + 112U^6V - 84U^5V^2 + 140U^4V^3 + 490U^3V^4 + 1596U^2V^5 + 2807UV^6 + 2119V^7,$$

where $U, V \in \mathbb{Z}$ are related to $X, Y$ via the unimodular substitution

$$U = 2X + 11Y \quad \text{and} \quad V = 7X + 39Y.$$

We applied the Thue–Mahler solver to this and found that it has no solutions. Next we take $f = f_2$ which also has Hecke eigenfield $K_f = \mathbb{Q}(\sqrt{2})$. We apply Lemmata 14.2, 14.3 and 14.6 using the same sets of primes $p_j$ and $\ell_i$ as for $f_1$. We find $\mathcal{E}_f = (1 - 2\sqrt{2})$, and so $n = (1 - 2\sqrt{2})$ and $n = 7$. Again we obtain $\mathcal{Z} = \{0, 8\}$ on applying Lemma 14.3. We find that $\mathcal{W} = \emptyset$ for $m = 0$ and $\mathcal{W} = \{\epsilon^3\}$ for $m = 8$. Again the corresponding Thue–Mahler equation has no solutions. Thus (72) has no solutions with $n \geq 7$ prime for $q = 31, \delta = 1$ and with $y$ odd (i.e., $\kappa = 5$) and $k \equiv 0$ (mod 2). We used the above approach to deal with all the cases where $\mathcal{E}_f$ is nonzero. In all the cases where $\mathcal{E}_f = 0$, the newform $f$ is rational, and in fact corresponds to an elliptic curve $E/\mathbb{Q}$ with nontrivial 2-torsion. These elliptic curves are listed in Table 3. Thus $\tilde{\rho}_{G,n} \sim \tilde{\rho}_{E,n}$. What is required for Proposition 14.1 is to show in these cases that there are no solutions with prime $7 \leq n < 1000$ apart from the ones listed in the statement of the proposition. We illustrate how this works by taking $(q, \delta, \kappa, v) = (7, 0, 1, 0)$. There is a unique newform $f$ of weight 2
and level \( N = 2^k q = 14 \) which corresponds to the elliptic curve

\[
Y^2 + XY + Y = X^3 + 4X - 6
\]

with Cremona label 14a1. For each prime \( 7 \leq n < 1000 \) we computed \( Z = Z_{\ell_1, \ldots, \ell_r} \) as given by Lemma 14.3. Here we chose \( \ell_1, \ldots, \ell_r \) to be the primes \( \neq q \) satisfying (i) and (ii) with \( t \leq 200 \).

![Table 4. For the quadruple \((q, \delta, \kappa, v) = (7, 0, 1, 0)\) and for prime \(7 \leq n < 1000\) we computed \(Z = Z_{\ell_1, \ldots, \ell_r}\) as given by Lemma 14.3. Here we chose \(\ell_1, \ldots, \ell_r\) to be the primes \(\neq q\) satisfying (i) and (ii) with \(t \leq 200\).](image)

The results of this computation are summarized in Table 4. Note that by Lemma 14.3, 

\[
\left( k \mod 2^n \right) \in \mathbb{Z}.
\]

We deduce that there are no solutions for prime \(n\) satisfying \(17 \leq n < 1000, n \neq 41\). For \(n = 7, 11, 13\) and \(41\), and for each \(m\) in the corresponding \(Z\), we compute \(W = W_{\ell_1, \ldots, \ell_r}\) as in Lemma 14.6 where \(\ell_1, \ldots, \ell_r\) are now the primes \(\neq q\) satisfying (a), (b) and (c) with \(t \leq 800\). We found that \(W = \emptyset\) in all cases except for \(n = 7, m = 0\), when \(W = 11 - \sqrt{-7}\). It follows from Lemma 14.6 that

\[
x + 7^k \sqrt{-7} = (11 - \sqrt{-7}) \cdot \alpha^7
\]

where \(\alpha \in \mathbb{Z}[\theta]\) where \(\theta = (1 + \sqrt{-7})/2\). Write \(\alpha = (X + Y\theta)\) with \(X, Y \in \mathbb{Z}\). Thus

\[
\frac{x - 7^k}{2} + 7^k \cdot \theta = (6 - \theta) \cdot (X + Y\theta)^7.
\]

Equating the coefficients of \(\theta\) on either side yields the Thue–Mahler equation

\[
-X^7 + 35X^6Y + 147X^5Y^2 - 105X^4Y^3 - 595X^3Y^4 - 231X^2Y^5 + 161XY^6 + 45Y^7 = 7^k.
\]

We find that the only solution is \((X, Y, k) = (-1, 0, 0)\). Hence \(x = -11\), and the corresponding solution to (72) is \(11^2 + 7 = 2^7\). We observe that \(-11 \equiv 1 \pmod{4}\) which is consistent with our assumption \(x \equiv 1 \pmod{4}\) if \(\kappa = 1\), made in the statement of Proposition 14.1. The other cases are similar.

**Proofs of Theorems 2 and 3.** We now deduce Theorems 2 and 3 from Proposition 14.1. These two theorems concern the equation

\[
x^2 - q^{2k+1} = y^n\]

with \(n \geq 3\) and \(q \nmid x\). Thus we are in the \(\delta = 1\) case of the proposition. By the remarks following the statement of the proposition we are reduced to the case \(n \geq 7\) is prime. Theorem 2 is concerned with the primes \(q\) appearing in (4), whilst Theorem 3 deals with \(q = 41, 73, 89\) and \(97\). A glance at Table 3 reveals that all the elliptic curves \(E\) appearing in Proposition 14.1 for the case \(\delta = 1\) in fact correspond to the values \(q = 41, 73, 89\) and \(97\). Theorems 2 and 3 now follow immediately from the proposition.
Theorem 3 only resolves $x^2 - 73^{2k+1} = y^n$ for $3 \leq n \leq 1000$. It is natural to ask whether we can apply the same technique, namely Lemma 14.3, to show that there are no solutions for prime exponents $n$ in the range $1000 < n < 6 \times 10^6$. Write $n_u$ for the smallest prime $> 2^u$. For $10 \leq u \leq 22$ the prime $n = n_u$ belongs to the range $1000 < n < 6 \times 10^6$. The table lists the primes $n = n_u$ in this range and, for each, a set of primes $\ell_1, \ldots, \ell_r$ satisfying conditions (i), (ii) such that $\mathcal{Z}_{\ell_1, \ldots, \ell_r} = \emptyset$. It also records the time the computation took for each of these values of $n$, on a single processor.

| $n$ | $\{\ell_1, \ldots, \ell_r\}$ | time (seconds) |
|-----|--------------------------------|---------------|
| $2^{10} + 7 = 1031$ | $\{2063, 12373, 30931\}$ | 0.18          |
| $2^{11} + 5 = 2053$ | $\{94439, 110863, 143711, 168347, 197089\}$ | 7.75          |
| $2^{12} + 3 = 4099$ | $\{73783, 98377, 114773\}$ | 4.39          |
| $2^{13} + 17 = 8209$ | $\{246271, 525377, 574631\}$ | 15.50         |
| $2^{14} + 27 = 16411$ | $\{98467, 459509, 590797\}$ | 6.19          |
| $2^{15} + 3 = 32771$ | $\{65543, 983131, 1179757\}$ | 3.91          |
| $2^{16} + 1 = 65537$ | $\{917519, 1310741, 1703963, 2359333\}$ | 57.51         |
| $2^{17} + 29 = 131101$ | $\{2097617, 9439273, 11799091, 12585697\}$ | 142.59        |
| $2^{18} + 3 = 262147$ | $\{1048589, 4194353, 6291529\}$ | 65.89         |
| $2^{19} + 21 = 524309$ | $\{6291709, 10486181, 23069597\}$ | 402.12        |
| $2^{20} + 7 = 1048583$ | $\{20971661, 25165993, 44040487\}$ | 1319.57       |
| $2^{21} + 17 = 2097169$ | $\{37749043, 176162197, 188745211\}$ | 2468.46       |
| $2^{22} + 15 = 4194319$ | $\{75497743, 92275019, 100663657\}$ | 4983.07       |

**Table 5.** Write $n_u$ for the smallest prime $> 2^u$. For $10 \leq u \leq 22$ the prime $n = n_u$ belongs to the range $1000 < n < 6 \times 10^6$. The table lists the primes $n = n_u$ in this range and, for each, a set of primes $\ell_1, \ldots, \ell_r$ satisfying conditions (i), (ii) such that $\mathcal{Z}_{\ell_1, \ldots, \ell_r} = \emptyset$. It also records the time the computation took for each of these values of $n$, on a single processor.

**Remark.** It is well-known that the exponent $n$ can be explicitly bounded in (72) in terms of the prime $q$. For example, if $\delta = 1$ and $\kappa = 5$ (i.e., $y$ is odd) then Bugeaud [1997] showed that

$$n \leq 4.5 \times 10^6 q^2 \log^2 q.$$  \[(76)\]

Let $(q, \delta, \kappa, v) = (73, 1, 5, 1)$ and $E$ be the elliptic curve with Cremona label 2336a1; this is one of the two outstanding cases from Table 3 for which the bound (76) is applicable. We are in fact able to substantially improve this bound for the case in consideration through a specialization and minor refinement (we omit the details) of Bugeaud’s approach and deduce that

$$n < 6 \times 10^6.$$  

**Theorem 3** only resolves $x^2 - 73^{2k+1} = y^n$ for $3 \leq n \leq 1000$. It is natural to ask whether we can apply the same technique, namely Lemma 14.3, to show that there are no solutions for prime exponents $n$ in the range $1000 < n < 6 \times 10^6$. Write $n_u$ for the smallest prime $> 2^u$. For $10 \leq u \leq 22$ the prime $n = n_u$ belongs to the range $1000 < n < 6 \times 10^6$. For each of these 13 primes we computed primes $\ell_1, \ldots, \ell_r$ satisfying conditions (i) and (ii) such that $\mathcal{Z}_{\ell_1, \ldots, \ell_r} = \emptyset$, whence by Lemma 14.3 there are no solutions for that particular exponent $n$. Table 5 records the values of $\ell_1, \ldots, \ell_r$ as well as the time taken to perform the corresponding computation in Magma on a single processor. There are 412681 primes in the range $1000 < n < 6 \times 10^6$. On the basis of the timing in the table we crudely estimate that it would take around 60 years to carry out the computation (on a single processor) for all 412681 primes.
We shall shortly give a substantially faster method for treating the case $\delta = 0$. Alas this method is not available for $\delta = 1$, as we explain in due course.

### 15. The proof of Theorem 1: large exponents

We now complete the proof of Theorem 1 which is concerned, for prime $3 \leq q < 100$, with the equation

$$x^2 + q^\alpha = y^n,$$

subject to the assumptions that $q \nmid x$ and $n \geq 3$. The exponents $n = 3$ and $n = 4$ were treated in Section 2, so we may suppose that $n \geq 5$ is prime. The case $\alpha = 2k$ was handled in Section 5, so we suppose further that $\alpha = 2k + 1$. The case with $y$ odd was the topic of Section 11, so we may assume that $y$ is even. Finally, the case with exponent $n = 5$ was resolved in Section 12, whence we may suppose that $n \geq 7$ is prime. To summarize, we are reduced to treating the equation

$$x^2 + q^{2k+1} = y^n, \quad k \geq 0, \; q \nmid x, \; y \text{ even}, \; n \geq 7 \text{ prime}. \quad (77)$$

By Proposition 14.1, we may in fact suppose that $n > 1000$ and that

$$q \in \{7, 23, 31, 47, 71, 79\}. \quad (78)$$

For convenience, we restate Proposition 14.1 specialized to our current situation.

**Lemma 15.1.** Let $q$ be one of the values in (78). Let $(x, y, k)$ satisfy (77), where $n > 1000$ is prime. Suppose, without loss of generality, that $x \equiv 1 \pmod{4}$. Attach to this solution the Frey–Hellegouarch elliptic curve

$$G = G_{x,k} : Y^2 = X^3 + 4xX^2 + 4(x^2 + q^{2k+1})X.$$

Then $\bar{\rho}_{G,n} \sim \bar{\rho}_{E,n}$ where $E$ is an elliptic curve of conductor $2q$ and nontrivial 2-torsion given in Table 6.

**Upper bounds for $n$: linear forms in logarithms, complex and $q$-adic.** We will appeal to bounds for linear forms in logarithms to deduce an upper bound for the prime exponent $n$ in (77) where $q$ belongs to (78).

| $q$ | Cremona label for $E$ | minimal model for $E$ |
|-----|-----------------------|----------------------|
| 7   | 144a1                 | $Y^2 + XY + Y = X^3 + 4X - 6$ |
| 23  | 46a1                  | $Y^2 + XY = X^3 - X^2 - 10X - 12$ |
| 31  | 62a1                  | $Y^2 + XY + Y = X^3 - X^2 - X + 1$ |
| 47  | 94a1                  | $Y^2 + XY + Y = X^3 - X^2 - 1$ |
| 71  | 142c1                 | $Y^2 + XY = X^3 - X^2 - X - 3$ |
| 79  | 158e1                 | $Y^2 + XY + Y = X^3 + X^2 + X + 1$ |

Table 6. Elliptic curve $E$ of conductor $2q$ and nontrivial 2-torsion.
Proposition 15.2. Let $q$ belong to the list (78). Let $(x, y, k)$ satisfy (77) with prime exponent $n > 1000$. Then $n < U_q$ where

$$
U_q = \begin{cases}
2.8 \times 10^8 & \text{if } q = 7, \\
1.1 \times 10^9 & \text{if } q = 23, \\
5.0 \times 10^8 & \text{if } q = 31, \\
2.2 \times 10^9 & \text{if } q = 47, \\
2.3 \times 10^9 & \text{if } q = 71, \\
2.2 \times 10^9 & \text{if } q = 79.
\end{cases}
$$

To obtain this result, our first order of business will be to produce a lower bound upon $y$.

Lemma 15.3. If there exists a solution to (77), then $y > 4n - 4\sqrt{2n} + 2$.

Proof. We suppose without loss of generality that $x \equiv 1 \pmod{4}$, so that we can apply Lemma 15.1. We first show that $y$ is divisible by an odd prime. Suppose otherwise and write $y = 2^\mu$ with $\mu \geq 1$. Then the Frey–Hellegouarch curve $G_{x,k}$ has conductor $2q$ and minimal discriminant $-2^{2\mu-12}q^{2k+1}$. A short search of Cremona’s tables [1997] reveals that there are no such elliptic curves for the values $q$ in (78) (recall that $n > 1000$). Thus, there necessarily exists an odd prime $p \mid y$; since $q \nmid y$, we observe that $q \neq p$. By Lemma 7.1,

$$a_p(E) \equiv \pm (p + 1) \pmod{n},$$

where $E$ is given by Table 6. As $E$ has nontrivial 2-torsion, we conclude that $2n \mid (p + 1 \mp a_p(E))$. However, from the Hasse–Weil bounds,

$$0 < p + 1 \mp a_p(E) < (\sqrt{p} + 1)^2 \leq (\sqrt{y/2} + 1)^2,$$

and therefore $2n < (\sqrt{y/2} + 1)^2$. The desired inequality follows. 

Now let $q$ be any of the values in (78), write $M = \mathbb{Q}(\sqrt{-q})$, and let $\mathcal{O}_M$ be its ring of integers. Note that the units of $\mathcal{O}_M$ are $\pm 1$. Fix $\mathfrak{P}$ to be one of the two prime ideals of $\mathcal{O}_M$ above 2. After possibly replacing $x$ by $-x$ we have

$$
\frac{x + q^k \sqrt{-q}}{2} \cdot \mathcal{O}_M = \mathfrak{P}^{n-2} \cdot \mathfrak{A}^n,
$$

where $\mathfrak{A}$ is an ideal of $\mathcal{O}_M$ with norm $y/2$. Hence

$$
\frac{x - q^k \sqrt{-q}}{x + q^k \sqrt{-q}} = \left(\frac{\mathfrak{P}}{\mathfrak{A}}\right)^2 \cdot \left(\frac{\mathfrak{P} \cdot \mathfrak{A}}{\mathfrak{P} \cdot \mathfrak{A}}\right)^n.
$$

For all six values of $q$ under consideration, the class group is cyclic and generated by the class $[\mathfrak{P}]$. Let $h_q$ be the class number of $M$; this value is respectively 1, 3, 3, 5, 7 and 5 for $q$ in (78) (see Table 7). As $n > 1000$ is prime, $\gcd(n, h_q) = 1$. Since $\mathcal{O}_M$ has class number $h_q$, it follows that $\mathfrak{P}^{h_q}$ is principal, say $\mathfrak{P}^{h_q} = (\alpha_q) \cdot \mathcal{O}_M$. We fix our choice of $\mathfrak{P}$ so that $\alpha_q$ is given by Table 7. Write $\beta_q = \alpha_q/\overline{\alpha}_q$. Thus

$$
\left(\frac{x - q^k \sqrt{-q}}{x + q^k \sqrt{-q}}\right)^{h_q} = \beta_q^2 y^n,
$$

(81)
Differences between perfect powers: prime power gaps 1835

\[ \begin{array}{|c|cccccc|} \hline q & 7 & 23 & 31 & 47 & 71 & 79 \\ \hline h_q & 1 & 3 & 3 & 5 & 7 & 5 \\ \alpha_q & \frac{1+\sqrt{-7}}{2} & \frac{3+\sqrt{-23}}{2} & \frac{1+\sqrt{-31}}{2} & \frac{9+\sqrt{-47}}{2} & \frac{21+\sqrt{-71}}{2} & \frac{7+\sqrt{-79}}{2} \\ \hline \end{array} \]

**Table 7.** Here, \( h_q \) denotes the class number of \( M = \mathbb{Q}(\sqrt{-q}) \), and \( \alpha_q \) is a generator for the principal ideal \( \mathfrak{p}^{h_q} \), where \( \mathfrak{p} \) is one of the two prime ideals of \( \mathcal{O}_M \) above 2.

where \( \gamma \in M \) is some generator for the principal ideal \( (\mathfrak{p} \cdot \mathfrak{A})/(\mathfrak{p} \cdot \mathfrak{A})^{h_q} \).

To derive an upper bound on \( n \), we begin by using (81) to find a “small” linear form in logarithms. Write

\[ \Lambda = \log \left( \frac{x - q^k \sqrt{-q}}{x + q^k \sqrt{-q}} \right). \]

**Lemma 15.4.** If there exists a solution to (77) with \( y^n > 100 q^{2k+1} \), then

\[ \log |\Lambda| < 0.75 + \left(k + \frac{1}{2}\right) \log q - \frac{n}{2} \log y. \]

**Proof.** The assumption that \( y^n > 100 q^{2k+1} \), together with, say, Lemma B.2 of [Smart 1998], implies that

\[ |\Lambda| \leq -10 \log \left( \frac{9}{10} \right) \left| \frac{x - q^k \sqrt{-q}}{x + q^k \sqrt{-q}} - 1 \right| = -20 \log \left( \frac{9}{10} \right) \frac{q^k \sqrt{q}}{y^{n/2}}, \]

whence the lemma follows. \( \square \)

To show that \( \log |\Lambda| \) here is indeed small, we first require an upper bound upon \( k \). From (81), we have

\[ \left( \frac{x - q^k \sqrt{-q}}{x + q^k \sqrt{-q}} \right)^{h_q} - 1 = \beta_q^2 y^n - 1 \]

and so

\[ \frac{-2q^k \sqrt{-q}}{x + q^k \sqrt{-q}} \sum_{i=0}^{h_q-1} \left( \frac{x - q^k \sqrt{-q}}{x + q^k \sqrt{-q}} \right)^i = \beta_q^2 y^n - 1. \]  \( (82) \)

Since \( \gcd(x, q) = 1 \), it follows from (82) that, if we set

\[ \Lambda_1 = y^n - \beta_q^2, \]

then \( \nu_q(\Lambda_1) \geq k \). To complement this with an upper bound for linear forms in \( q \)-adic logarithms, we appeal to Theorem 10, with

\[ q \in \{7, 23, 31, 47, 79\}, \quad f = 1, \quad D = 2, \quad \alpha_1 = \gamma, \quad \alpha_2 = \beta_q, \quad b_1 = n, \quad b_2 = 2, \]

\[ \log A_1 = \frac{h_q}{2} \log y, \quad \log A_2 = \frac{1}{2} \log q \quad \text{and} \quad b' = \frac{n}{\log q} + \frac{2}{h_q \log y}. \]

Here, we use Lemma 13.2 of Bugeaud, Mignotte and Siksek [Bugeaud et al. 2006] which implies that

\[ h(\alpha_1) = \frac{h_q}{2} \log y \quad \text{and} \quad h(\alpha_2) = \frac{h_q}{2} \log 2. \]
In the case $q = 71$, we make identical choices except to take $\log A_2 = \frac{7}{2} \log 2$, whence

$$b' = \frac{n}{7 \log 2} + \frac{2}{7 \log y}.$$ 

Theorem 10 thus yields the inequality

$$v_q(\Lambda_1) \leq \frac{96 q h_q}{\log^3 q} \cdot (\max \{ \log b' + \log \log q + 0.4, 5 \log q \})^2 \log y,$$

for $q \in \{7, 23, 31, 47, 79\}$, and

$$v_{71}(\Lambda_1) \leq 701.2 \cdot (\max \{ \log b' + \log \log 71 + 0.4, 5 \log 71 \})^2 \log y,$$

if $q = 71$.

Let us now suppose that

$$n > 10^8,$$ \hfill (83)

which will certainly be the case if $n \geq U_q$, for $U_q$ as defined in (79). Then, from Lemma 15.3, in all cases we have that

$$b' < 1.001 \frac{n}{\log q}$$

and hence obtain the inequalities

$$k < \frac{96 q h_q}{\log^3 q} \cdot (\max \{ \log n + 0.4001, 5 \log q \})^2 \log y, \quad \text{if } q \in \{7, 23, 31, 47, 79\} \hfill (84)$$

and

$$k < 701.2 \cdot (\max \{ \log n + 0.4001, 5 \log 71 \})^2 \log y, \quad \text{if } q = 71. \hfill (85)$$

Now consider

$$\Lambda_2 = h_q \log \frac{x - q^k \sqrt{-q}}{x + q^k \sqrt{-q}} = n \log (\epsilon_1 \gamma) + 2 \log (\epsilon_2 \beta_q) + j \pi i,$$ \hfill (86)

where we take the principal branches of the logarithms and the integers $\epsilon_i \in \{-1, 1\}$ and $j$ are chosen so that $\text{Im}(\log(\epsilon_1 \gamma))$ and $\text{Im}(\log(\epsilon_2 \beta_q))$ have opposite signs, and we have both

$$|\log(\epsilon_2 \beta_q)| < \frac{\pi}{2}$$

and $|\Lambda_2|$ minimal. Explicitly,

| $q$  | 7  | 23 | 31 | 47 | 71 | 79 |
|------|----|----|----|----|----|----|
| $\epsilon_2$ | -1 | -1 | -1 | 1  | 1  | -1 |
| $|\log(\epsilon_2 \beta_q)|$ | $\arccos \frac{3}{4}$ | $\arccos \frac{7}{16}$ | $\arccos \frac{15}{16}$ | $\arccos \frac{17}{64}$ | $\arccos \frac{185}{256}$ | $\arccos \frac{15}{64}$ |
Assume first that

$$y^n \leq 100 q^{2k+1}.$$
If \( q \in \{7, 23, 31, 47, 79\} \), it follows from (84) that
\[
n < \frac{2 \log 10}{\log y} + \frac{\log q}{\log y} + \frac{192 q h_q}{\log^2 q} \cdot (\max\{\log n + 0.4001, 5 \log q\})^2,
\]
in each case contradicting Lemma 15.3 and (83). We obtain a similar contradiction in case the \( q = 71 \) upon considering (85).

It follows, then, that we may assume \( y^n > 100 q^{2k+1} \) and hence conclude, from Lemma 15.4, that
\[
\log |\Lambda_2| < \log h_q + 0.75 + \left(k + \frac{1}{2}\right) \log q - \frac{n}{2} \log y.
\]

If \( q \in \{7, 23, 31, 47, 79\} \), (84) thus implies that
\[
\log |\Lambda_2| < \log h_q + 0.75 + \frac{1}{2} \log q + \frac{96 q h_q}{\log^2 q} \cdot (\max\{\log n + 0.4001, 5 \log q\})^2 \log y - \frac{n}{2} \log y.
\]

An analogous inequality holds for \( q = 71 \), upon appealing to (85). From Lemma 15.3 and (83), we find that
\[
\log |\Lambda_2| < -\kappa_q n \log y,
\]
where
\[
\kappa_q = \begin{cases}
0.499 & \text{if } q = 7, \\
0.497 & \text{if } q \in \{23, 31\}, \\
0.494 & \text{if } q = 47, \\
0.486 & \text{if } q = 71, \\
0.490 & \text{if } q = 79.
\end{cases}
\]

It therefore follows from the definition of \( \Lambda_2 \) that
\[
|j| \pi < \pi n + 2 \arccos \frac{15}{64} + y^{-0.486 n} < \pi n + \pi,
\]
and so
\[
|j| \leq n.
\]  

**Linear forms in three logarithms.** To deduce an initial lower bound upon the linear form in logarithms \( |\Lambda_2| \), we will use the following.

**Theorem 14** [Matveev 2000, Theorem 2.1]. Let \( \mathbb{K} \) be an algebraic number field of degree \( D \) over \( \mathbb{Q} \) and put \( \chi = 1 \) if \( \mathbb{K} \) is real, \( \chi = 2 \) otherwise. Suppose that \( \alpha_1, \alpha_2, \ldots, \alpha_{n_0} \in \mathbb{K}^* \) with absolute logarithmic heights \( h(\alpha_i) \) for \( 1 \leq i \leq n_0 \), and suppose that
\[
A_i \geq \max\{D h(\alpha_i), |\log\alpha_i|\}, \quad 1 \leq i \leq n_0,
\]
for some fixed choice of the logarithm. Define
\[
\Lambda = b_1 \log \alpha_1 + \cdots + b_{n_0} \log \alpha_{n_0},
\]
where the \( b_i \) are integers and set
\[
B = \max\left\{1, \max\left\{|b_i| \frac{A_i}{A_{n_0}} : 1 \leq i \leq n_0\}\right\}.
\]
Define, with $e := \exp(1)$,
\[
\Omega = A_1 \cdots A_{n_0}, \quad C(n_0) = C(n_0, \chi) = \frac{16}{n_0!} e^{n_0} (2n_0 + 1 + 2\chi)(n_0 + 2)(4n_0 + 4)^{n_0+1} \left(\frac{en_0}{2}\right)^\chi,
\]
\[
C_0 = \log(e^{4.4n_0+7} n_0^{5.5} D^2 \log(eD)) \quad \text{and} \quad W_0 = \log(1.5eBD \log(eD)).
\]

Then, if $\log \alpha_1, \ldots, \log \alpha_{n_0}$ are linearly independent over $\mathbb{Z}$ and $b_{n_0} \neq 0$, we have
\[
\log |\Lambda| > -C(n_0) C_0 W_0 D^2 \Omega.
\]

We apply Theorem 14 to $\Lambda = \Lambda_2$ with
\[
D = 2, \quad \chi = 2, \quad n_0 = 3, \quad b_3 = n, \quad \alpha_3 = \epsilon_1 \gamma, \quad b_2 = -2, \quad \alpha_2 = \epsilon_2 \beta_q, \quad b_1 = j \quad \text{and} \quad \alpha_1 = -1.
\]
We may thus take
\[
A_3 = \log y, \quad A_2 = \max\{h_q \log 2, |\log(\epsilon_2 \beta_q)|\}, \quad A_1 = \pi \quad \text{and} \quad B = n.
\]
Since
\[
4 C(3) C_0 = 2^{18} \cdot 3 \cdot 5 \cdot 11 \cdot e^5 \cdot \log(e^{20.2} \cdot 3^{5.5} \cdot 4 \log(2e)) < 1.80741 \times 10^{11},
\]
and
\[
W_0 = \log(3e \log(2e)) < 2.63 + \log n,
\]
we may therefore conclude that
\[
\log |\Lambda_2| > -5.68 \times 10^{11} \max\{h_q \log 2, |\log(\epsilon_2 \beta_q)|\}(2.63 + \log n) \log y.
\]
It thus follows from (87) that
\[
n < \kappa_q^{-1} 5.68 \times 10^{11} \max\{h_q \log 2, |\log(\epsilon_2 \beta_q)|\}(2.63 + \log n)
\]
and hence
\[
n < \begin{cases} 
2.77 \times 10^{13} & \text{if } q = 7, \\
8.24 \times 10^{13} & \text{if } q \in \{23, 31\}, \\
1.42 \times 10^{14} & \text{if } q \in \{47, 79\}, \\
2.02 \times 10^{14} & \text{if } q = 71.
\end{cases} 
\]

To improve these inequalities, we appeal to a sharper, rather complicated, lower bound for linear forms in three complex logarithms, due to Mignotte [2008, Theorem 2]. Our argument is very similar to that employed in a recent paper of the authors [Bennett and Siksek 2023]. We note that recent work of Mignotte and Voutier [2022] would substantially improve our bounds (and reduce our subsequent computations considerably).

**Theorem 15** (Mignotte). Consider three nonzero algebraic numbers $\alpha_1, \alpha_2$ and $\alpha_3$, which are either all real and $> 1$, or all complex of modulus one and all $\neq 1$. In addition, assume that the three numbers $\alpha_1, \alpha_2$ and $\alpha_3$ are either all multiplicatively independent, or that two of the numbers are multiplicatively
independent and the third is a root of unity. We also consider three positive rational integers \(b_1, b_2, b_3\) with \(\gcd(b_1, b_2, b_3) = 1\), and the linear form

\[
\Lambda = b_2 \log \alpha_2 - b_1 \log \alpha_1 - b_3 \log \alpha_3,
\]

where the logarithms of the \(\alpha_i\) are arbitrary determinations of the logarithm, but which are all real or all purely imaginary. We assume that

\[
0 < |\Lambda| < \frac{2\pi}{w},
\]

where \(w\) is the maximal order of a root of unity in \(\mathbb{Q}(\alpha_1, \alpha_2, \alpha_3)\). Suppose further that

\[
b_2|\log \alpha_2| = b_1|\log \alpha_1| + b_3|\log \alpha_3| \pm |\Lambda|
\]

and put

\[
d_1 = \gcd(b_1, b_2), \quad d_3 = \gcd(b_3, b_2) \quad \text{and} \quad b_2 = d_1b_2' = d_3b_2''
\]

Let \(K, L, R, R_1, R_2, R_3, S, S_1, S_2, S_3, T, T_1, T_2, T_3\) be positive rational integers with

\[K \geq 3, \quad L \geq 5, \quad R > R_1 + R_2 + R_3, \quad S > S_1 + S_2 + S_3 \quad \text{and} \quad T > T_1 + T_2 + T_3.\]

Let \(\rho \geq 2\) be a real number. Let \(a_1, a_2\) and \(a_3\) be real numbers such that

\[a_i \geq \rho|\log \alpha_i| - \log|\alpha_i| + 2D h(\alpha_i), \quad i = 1, 2, 3,\]

where \(D = [\mathbb{Q}(\alpha_1, \alpha_2, \alpha_3) : \mathbb{Q}] / [\mathbb{R}(\alpha_1, \alpha_2, \alpha_3) : \mathbb{R}]\), and set

\[U = \left(\frac{KL}{2} + \frac{L}{4} - 1 - \frac{2K}{3L}\right) \log \rho.\]

Assume further that

\[U \geq (D + 1) \log(K^2L) + gL(a_1R + a_2S + a_3T) + D(K - 1) \log b - 2\log \frac{e}{2},\]

where

\[g = \frac{1}{4} - \frac{K^2L}{12RST} \quad \text{and} \quad b = (b_2'\eta_0)(b_3''\xi_0) \left(\prod_{k=1}^{K-1} k!\right)^{-\frac{4}{(K(K-1))}},\]

with

\[\eta_0 = \frac{R-1}{2} + \frac{(S-1)b_1}{2b_2} \quad \text{and} \quad \xi_0 = \frac{T-1}{2} + \frac{(S-1)b_3}{2b_2}.\]

Put

\[V = \sqrt((R_1 + 1)(S_1 + 1)(T_1 + 1)).\]

If, for some positive real number \(\chi\), we have

(i) \((R_1 + 1)(S_1 + 1)(T_1 + 1) > KM\),

(ii) \(\text{Card}\{\alpha_i^r \alpha_2^s \alpha_3^t : 0 \leq r \leq R_1, 0 \leq s \leq S_1, 0 \leq t \leq T_1\} > L\),

(iii) \((R_2 + 1)(S_2 + 1)(T_2 + 1) > 2K^2\),

(iv) \(\text{Card}\{\alpha_i^r \alpha_2^s \alpha_3^t : 0 \leq r \leq R_2, 0 \leq s \leq S_2, 0 \leq t \leq T_2\} > 2KL\), and
(v) \((R_3 + 1)(S_3 + 1)(T_3 + 1) > 6K^2L\),

where
\[
\mathcal{M} = \max\{R_1 + S_1 + 1, S_1 + T_1 + 1, R_1 + T_1 + 1, \chi V\},
\]

then either
\[
|\Lambda| \cdot \frac{L Se^{L|\Lambda|/(2b_2)}}{2|b_2|} > \rho^{-KL}, \tag{93}
\]
or at least one of the following conditions holds:

(C1) \(|b_1| \leq R_1\) and \(|b_2| \leq S_1\) and \(|b_3| \leq T_1\).

(C2) \(|b_1| \leq R_2\) and \(|b_2| \leq S_2\) and \(|b_3| \leq T_2\).

(C3) Either there exist nonzero rational integers \(r_0\) and \(s_0\) such that
\[
r_0b_2 = s_0b_1 \tag{94}
\]
with
\[
|r_0| \leq \frac{(R_1 + 1)(T_1 + 1)}{\mathcal{M} - T_1} \quad \text{and} \quad |s_0| \leq \frac{(S_1 + 1)(T_1 + 1)}{\mathcal{M} - T_1}, \tag{95}
\]
or there exist rational integers \(r_1, s_1, t_1\) and \(t_2\), with \(r_1s_1 \neq 0\), such that
\[
(t_1b_1 + r_1b_3)s_1 = r_1b_2t_2, \quad \gcd(r_1, t_1) = \gcd(s_1, t_2) = 1, \tag{96}
\]
which also satisfy
\[
|r_1s_1| \leq \gcd(r_1, s_1) \cdot \frac{(R_1 + 1)(S_1 + 1)}{\mathcal{M} - \max\{R_1, S_1\}},
|s_1t_1| \leq \gcd(r_1, s_1) \cdot \frac{(S_1 + 1)(T_1 + 1)}{\mathcal{M} - \max\{S_1, T_1\}}
\]
and
\[
|r_1t_2| \leq \gcd(r_1, s_1) \cdot \frac{(R_1 + 1)(T_1 + 1)}{\mathcal{M} - \max\{R_1, T_1\}}.
\]

Also, when \(t_1 = 0\) we can take \(r_1 = 1\), and when \(t_2 = 0\) we can take \(s_1 = 1\).

We will apply this result to \(\Lambda = \Lambda_2\). For simplicity, we will provide full details for the case \(q = 7\); the arguments for the other values of \(q\) under consideration are similar and follow closely their analogues in [Bennett and Siksek 2023]. If \(j = 0\), then \(\Lambda_2\) immediately reduces to a linear form in two logarithms and we may appeal to Theorem 11, with (in the notation of that result)
\[
c_2 = n, \quad \beta_2 = \epsilon_1\gamma, \quad c_1 = 2, \quad \beta_1 = \frac{1}{\epsilon_2\beta_q}, \quad D = 1,
\]
whence we may choose
\[
\log B_2 = \frac{1}{2} \log y \quad \text{and} \quad \log B_1 = 1.
\]
We thus have, from (83) and Lemma 15.3,
\[
b' = \frac{4}{\log y} + n < 1.001n.
\]
From Theorem 11 with \((m, C) = (10, 32, 3)\), it follows, again from (83), that
\[
\log |\Lambda_2| \geq -64.6(\log n + 0.211)^2 \log y.
\]
Combining this with inequality (87) contradicts (83). We argue similarly if \(j = \pm n\), again reaching a contradiction via bounds for linear forms in two complex logarithms.

We may thus suppose that \(j \neq 0\) and \(|j| < n\) (so that, in particular, \(\gcd(j, n) = 1\)), and hence choose
\[
b_1 = 2, \quad \alpha_1 = \frac{1}{\epsilon_2 \beta_q}, \quad b_2 = n, \quad \alpha_2 = \epsilon_1 \gamma, \quad b_3 = -j \quad \text{and} \quad \alpha_3 = -1.
\]
From the fact that \(\text{Im}(\log(\epsilon_1 \gamma))\) and \(\text{Im}(\log(\epsilon_2 \beta_q))\) have opposite signs, (91) is satisfied and we have
\[
d_1 = d_3 = 1 \quad \text{and} \quad b'_2 = b''_2 = n.
\]
It follows that
\[
h(\alpha_1) = \frac{1}{2} \log(2), \quad h(\alpha_2) = \frac{1}{2} \log(y) \quad \text{and} \quad h(\alpha_3) = 0,
\]
and hence we can take
\[
a_1 = \rho \arccos \frac{3}{4} + \log 2, \quad a_2 = \rho \pi + \log y \quad \text{and} \quad a_3 = \rho \pi.
\]
As noted in [Bugeaud et al. 2006], if we suppose that \(m \geq 1\) and define
\[
K = [mL a_1 a_2 a_3], \quad R_1 = [c_1 a_2 a_3], \quad S_1 = [c_1 a_1 a_3], \quad T_1 = [c_1 a_1 a_2], \quad R_2 = [c_2 a_2 a_3], \quad S_2 = [c_2 a_1 a_3], \quad T_2 = [c_2 a_1 a_2], \quad R_3 = [c_3 a_2 a_3], \quad S_3 = [c_3 a_1 a_3], \quad T_3 = [c_3 a_1 a_2],
\]
where
\[
c_1 = \max \left\{ (\chi m L)^{2/3}, \left( \frac{2mL}{a_1} \right)^{1/2} \right\}, \quad c_2 = \max \left\{ 2^{1/3} (mL)^{2/3}, \left( \frac{m}{a_1} \right)^{1/2} L \right\} \quad \text{and} \quad c_3 = (6m^2)^{1/3} L,
\]
then conditions (i)–(v) are automatically satisfied. It remains to verify inequality (92).

To carry this out, we optimize numerically over values of \(\rho, L, m\) and \(\chi\) as in [Bennett and Siksek 2023] (full details are available there, by way of example, in the case \(q = 7\)). Pari/GP code for carrying this out is due to Voutier [2023]. In each case, we obtain a sharpened upper bound upon the exponent \(n\), provided inequality (93) holds. If, on the other hand, inequality (93) fails to be satisfied, from inequality (83) and our choices of \(S_1\) and \(S_2\), necessarily (C3) holds and we may rewrite \(\Lambda_2\) as a linear form in two complex logarithms to which we can apply Theorem 11. In this case, we once again obtain a sharpened upper bound for \(n\). Iterating this process leads to the upper bounds \(U_q\) given in (79). We observe that direct application of the new bounds from [Mignotte and Voutier 2022], with the corresponding Pari/GP code, substantially sharpens these bounds, though this is not especially important for our purposes. This completes the proof of Proposition 15.2.
Proof of Theorem 1. We now finish the proof of Theorem 1. By the remarks at the beginning of the current section, we are reduced to considering solutions \((x, y, k)\) to (77), where \(q\) belongs to (78). Thanks to Propositions 14.1 and 15.2, we may suppose that the prime exponent \(n\) belongs to the range \(1000 < n < U_q\) where \(U_q\) is given by (79).

Lemma 15.5. Let \((x, y, k)\) be a solution to (77) where \(q\) belongs to (78) and the exponent \(n\) is a prime belonging to the range \(1000 < n < U_q\). Let \(M = \mathbb{Q}(\sqrt{-q})\). Let \(h_q\) and \(\alpha_q\) be as in Table 7, and choose \(i\) to be the unique integer \(0 \leq i \leq h_q - 1\) satisfying \(ni \equiv -2 \pmod{h_q}\). Write \(n^* = (-ni - 2)/h_q\). Then, after possibly changing the sign of \(x\),

\[
\frac{x + q^k \sqrt{-q}}{2} = \alpha_q^{n^*} \cdot \gamma^n,
\]

where \(\gamma \in \mathcal{O}_M\). Additionally, \(\text{Norm}(\gamma) = 2^{i-1} y\).

Proof. Recall that \(h_q\) is the class number of \(M\), and that \(\mathfrak{P}^{h_q} = \alpha_q \mathcal{O}_M\), where \(\mathfrak{P}\) is one of the two prime ideals of \(\mathcal{O}_M\) above 2. From (78), after possibly replacing \(x\) by \(-x\),

\[
\left(\frac{x + q^k \sqrt{-q}}{2}\right) \cdot \mathcal{O}_M = \mathfrak{P}^{-2} \cdot \mathfrak{A}^n,
\]

where \(\mathfrak{A}\) is an ideal of \(\mathcal{O}_M\) of norm \(y/2\). Now, for the values of \(q\) we are considering, the class group is cyclic and generated by \([\mathfrak{P}]\). Thus there is some \(0 \leq i \leq h_q - 1\) such that \(\mathfrak{P}^i \mathfrak{A}\) is principal. However,

\[
\left(\frac{x + q^k \sqrt{-q}}{2}\right) \cdot \mathcal{O}_M = \mathfrak{P}^{-ni-2} \cdot (\mathfrak{P}^i \cdot \mathfrak{A})^n.
\]

We deduce that \(\mathfrak{P}^{-ni-2}\) is principal. As the class \([\mathfrak{P}]\) generates the class group, we infer that \(i\) is the unique integer \(0 \leq i \leq h_q - 1\) satisfying \(ni \equiv -2 \pmod{h_q}\). Write \(n^* = (-ni - 2)/h_q\). As \(\mathfrak{P}^{h_q} = \alpha_q\), we have \(\mathfrak{P}^{-ni-2} = \alpha_q^{n^*} \cdot \mathcal{O}_M\). Hence

\[
\frac{x + q^k \sqrt{-q}}{2} = \alpha_q^{n^*} \cdot \gamma^n,
\]

where \(\gamma \in \mathcal{O}_M\) is a generator for the principal ideal \(\mathfrak{P}^i \mathfrak{A}\). We note that \(\text{Norm}(\gamma) = 2^{i-1} y\).

The following lemma, inspired by ideas of Kraus [1998], provides a computational framework for showing that (77) has no solutions for a particular exponent \(n\).

Lemma 15.6. Let \(q\) belong to the list (78) and let \(\beta_q = \alpha_q/\beta_q\). Let \(n\) be a prime belonging to the range \(1000 < n < U_q\). Let \(E\) be the elliptic curve given in Table 6. Let \(\ell \neq q\) be a prime satisfying the three conditions

(I) \(-q\) is a square modulo \(\ell\);

(II) \(\ell = tn + 1\) for some positive integer \(t\);

(III) \(\alpha_\ell(E)^2 \not\equiv 4 \pmod{n}\).
Let $\mathfrak{L}$ be one of the two prime ideals of $\mathcal{O}_M$ above $\ell$, and write $\mathbb{F}_\mathfrak{L} = \mathcal{O}_M/\mathfrak{L} \cong \mathbb{F}_\ell$. Let $\beta \in \mathbb{F}_\mathfrak{L}$ satisfy $\beta \equiv \overline{\alpha_q}/\alpha_q \pmod{\mathfrak{L}}$. Choose $g$ to be a cyclic generator for $\mathbb{F}_\mathfrak{L}^*$, set $h = g^n$, and define

$$X_{\ell,n} = \{\beta^{a^*} \cdot h^j : j = 0, 1, \ldots, t - 1\} \subset \mathbb{F}_\mathfrak{L}.$$  

For $x \in X_{\ell,n}$ let

$$E_x : Y^2 = X(X + 1)(X + x).$$

Finally, define

$$\mathcal{Y}_{\ell,n} = \{x \in X : a_{\mathcal{L}}(E_x)^2 \equiv a_{\ell}(E)^2 \pmod{n}\}.$$ 

If $\mathcal{Y}_{\ell,n} = \emptyset$, then (77) has no solutions.

**Proof.** Suppose that $(x, y, k)$ is a solution to (77) for our particular pair $(q, n)$. We change the sign of $x$ if necessary so that (100) holds and let $x' = \pm x$ so that $x' \equiv 1 \pmod{4}$. By Lemma 15.1, we know that $\overline{\rho}_{G_{x',k,n}} \sim \overline{\rho}_{E,n}$. Observe that $G_{x',k}$ is either the same elliptic curve as $G_{x,k}$ if $x' = x$, or it is a quadratic twist by $-1$ if $x' = -x$. Hence $a_{\ell}(G_{x,k}) = \pm a_{\ell}(G_{x',k})$ for any odd prime $\ell$ of good reduction for either (and hence both) elliptic curves. We let $\ell$ be a prime satisfying conditions (I), (II) and (III). From (III) and (II), we note that $a_{\ell}(E) \not\equiv \pm (\ell + 1) \pmod{n}$. It follows from Lemma 7.1 that $\ell \nmid y$, and that $a_{\ell}(G_{x',k}) \equiv a_{\ell}(E) \pmod{n}$. Thus $a_{\ell}(G_{x,k})^2 \equiv a_{\ell}(E)^2 \pmod{n}$. By Lemma 15.5, identity (100) holds where $\text{Norm}(\gamma) = 2^{i-1}y$. In particular, $\mathcal{L}$ is disjoint from the support of $\gamma$ and $\alpha_q$. It follows from (100) that

$$\frac{x - q^k \sqrt{-q}}{x + q^k \sqrt{-q}} \equiv \left(\frac{\overline{\alpha_q}}{\alpha_q}\right)^n \cdot \left(\frac{\overline{\gamma}}{\gamma}\right)^n \pmod{n}.$$ 

As $g$ is a generator of $\mathbb{F}_\mathfrak{L}^*$ which is cyclic of order $\ell - 1 = tn$, and as $h = g^n$, there is some $0 \leq j \leq t - 1$ such that $(\overline{\gamma}/\gamma)^n \equiv h^j \pmod{\mathcal{L}}$. Hence

$$\frac{x - q^k \sqrt{-q}}{x + q^k \sqrt{-q}} \equiv x \pmod{\mathcal{L}},$$

for some $x \in X_{\ell,n}$. The Frey–Hellegouarch curve $G_{x,k}$ defined in Lemma 15.1 can be rewritten as

$$Y^2 = X(X + 2(x - q^k \sqrt{-q}))(X + 2(x + q^k \sqrt{-q})).$$

and hence modulo $\mathfrak{L}$ is a quadratic twist of $E_x$. We deduce that $a_{\mathcal{L}}(E_x)^2 \equiv a_{\ell}(G_{x,k})^2 \equiv a_{\ell}(E)^2 \pmod{n}$, whence $x \in \mathcal{Y}_{\ell,n}$. This completes the proof. \(\square\)

To finish the proof of Theorem 1, we wrote a Magma script which, for each $q$ in (78) and each prime $n$ in the interval $1000 < n < U_q$, found a prime $\ell$ satisfying conditions (I), (II) and (III), with $\mathcal{Y}_{\ell,n} = \emptyset$. The following table gives the approximate time taken for this computation, on a single processor:

| $q$   | 7  | 23 | 31 | 47 | 71 | 79 |
|-------|----|----|----|----|----|----|
| time (hours) | 115 | 450 | 226 | 988 | 1058 | 1019 |
As one may observe from our proofs, for a given $q$, the upper bound $U_q$ upon $n$ in (77), coming from bounds for linear forms in logarithms, depends strongly upon the class number of $\mathbb{Q}(\sqrt{-q})$. It is this dependence which makes extending Theorem 1 to larger values of $q$ an expensive proposition, computationally.

16. Concluding remarks

There are quite a few additional Frey–Hellegouarch curves at our disposal, that might prove helpful in completing the solution of (5), for some of our problematical values of $q$. A number of these arise from considering (5) as a special case of

$$x^2 - q^\delta z^\kappa = y^n,$$

where, say, $\kappa \in \{3, 4, 6\}$ and $0 \leq \delta < \kappa$. In each case, the dimensions of the spaces of modular forms under consideration grow quickly, complicating matters. This is particularly true if $\kappa \in \{4, 6\}$, where our Frey–Hellegouarch curve will a priori be defined over $\mathbb{Q}(\sqrt{q})$, and so the relevant modular forms are Hilbert modular forms which are more challenging to compute than classical modular forms.

In the case $y$ is even in (5) (whence we are in the situation where our bounds coming from linear forms in logarithms are weaker), we can attach a Frey–Hellegouarch $\mathbb{Q}$-curve to a potential solution (which at least corresponds to a classical modular form). To do this, write $M = \mathbb{Q}(\sqrt{q})$ and $\mathcal{O}_M$ for the ring of integers of $M$. Assuming that $M$ has class number one (which is the case for, say, the remaining values $q \in \{41, 89, 97\}$), we have

$$x + q^k \sqrt{q} = \frac{r^\gamma y^{n-2} \alpha^n}{2}$$

for some $r \in \mathbb{Z}$ and $\alpha \in \mathcal{O}_M$. Here, $\delta$ is a fundamental unit for $\mathcal{O}_M$ and $\gamma$ is a suitably chosen generator for one of the two prime ideals above 2 in $M$. From this equation,

$$q^k \sqrt{q} = \delta^r \gamma^{n-2} \alpha^n - \bar{\delta}^r \bar{\gamma}^{n-2} \bar{\alpha}^n.$$

Treating this as a ternary equation of signature $(n, n, 2)$, we can attach to such a solution a Frey–Hellegouarch $\mathbb{Q}$-curve; see, for example, [van Langen 2021, Section 6]. We will not pursue this here.

Acknowledgments

The authors are grateful to the anonymous referee for numerous insightful comments, and to Pedro-José Carzola Garcia, Ritesh Goenka and Vandita Patel for finding errors in earlier drafts of this paper.
