Abstract
In this paper we study the geometry and the topology of unbounded domains in the Hyperbolic Space $\mathbb{H}^n$ supporting a bounded positive solution to an overdetermined elliptic problem. Under suitable conditions on the elliptic problem and the behaviour of the bounded solution at infinity, we are able to show that symmetries of the boundary at infinity imply symmetries on the domain itself. In dimension two, we can strengthen our results proving that a connected domain $\Omega \subset \mathbb{H}^2$ with $C^2$ boundary whose complement is connected and supports a bounded positive solution $u$ to an overdetermined problem, assuming natural conditions on the equation and the behaviour at infinity of the solution, must be either a geodesic ball or, a horodisk or, a half-space determined by a complete equidistant curve or, the complement of any of the above example. Moreover, in each case, the solution $u$ is invariant by the isometries fixing $\Omega$.

Keywords: 35Nxx · 53Cxx

1 Introduction
Solving an elliptic partial derivative equation under Dirichlet or Neumann data is a classical problem but trying to impose both Dirichlet and Neumann data leads to a so called overdetermined elliptic problem (OEP) and solutions should be very rare. For example, consider...
the following problem in a domain (open and connected) $\Omega$ of $\mathbb{R}^n$,

$$
\begin{cases}
\Delta u + f(u) = 0 \text{ in } \Omega, \\
u > 0 \text{ in } \Omega, \\
u = 0 \text{ on } \partial \Omega, \\
\langle \nabla u, \vec{v} \rangle = \alpha \text{ on } \partial \Omega,
\end{cases}
$$

(1.1)

where $\vec{v}$ is the unit outward normal vector along $\partial \Omega$. A domain where the OEP (1.1) can be solved is called a $f$-extremal domain. If $\Omega$ is bounded and $f \equiv 1$, Serrin [20] proved that the ball is the only domain where the above problem admits a solution $u$ (this was generalized later to any Lipschitz function $f$). The proof of Serrin uses the moving plane method that was introduced by Alexandrov [1] in order to prove that round spheres are the only constant mean curvature embedded hypersurfaces in $\mathbb{R}^n$.

In [2], Berestycki, Caffarelli and Nirenberg considered the above problem for unbounded domains in $\mathbb{R}^n$ and proved that, under some additional hypotheses on $f$, the only $f$-extremal domain that is an epigraph is a halfspace. Moreover, they stated the following conjecture.

1.1 BCN conjecture

If $f$ is Lipschitz, and $\Omega$ is a smooth connected domain with $\mathbb{R}^n \setminus \overline{\Omega}$ connected where the OEP (1.1) admits a bounded solution, then $\Omega$ is either a ball, a halfspace, a cylinder $B^k \times \mathbb{R}^{n-k}$ ($B^k$ is a ball of $\mathbb{R}^k$) or the complement of one of them.

This conjecture is also motivated by the work of Reichel [15] concerning exterior domains. Besides it has inspired many interesting results: for example, the works of Farina and Valdinoci [8–10] about epigraphs or the one of Ros and Sicbaldi [16] concerning planar domains. Actually, in [21], Sicbaldi gave a counterexample to BCN conjecture in $\mathbb{R}^n$ for $n \geq 3$. But understanding the geometry of $f$-extremal domains is still an interesting question and one of the main point is the similarity of the geometry of these domains with the one of constant mean curvature hypersurfaces. Exploiting this similarity, Ros et al. [17] proved that in dimension 2 the BCN conjecture is true for unbounded domains whose complement is unbounded: it has to be a halfplane. Recently, Ros et al. [18] proved that the conditions imposed by Reichel [15] in order to obtain rigidity for exterior domains are necessary. The authors constructed nontrivial exterior domains that admits a positive bounded solution. We also refer to [7] for the study of overdetermined elliptic problems on a complete, non-compact Riemannian manifold without boundary and with non-negative Ricci tensor.

In this paper, we are interested in the geometry of $f$-extremal unbounded domains in the hyperbolic space. More precisely, let $\Omega \subset \mathbb{H}^n$ be a domain (open and connected) whose boundary, if not empty, is of class $C^2$ and consider the following OEP

$$
\begin{cases}
\Delta u + f(u) = 0 \text{ in } \Omega, \\
0 < u \leq C \text{ in } \Omega, \\
u = 0 \text{ on } \partial \Omega, \\
u(p) \to C \text{ uniformly as } d(p, \partial \Omega) \to +\infty \\
\langle \nabla u, \vec{v} \rangle = \alpha \text{ on } \partial \Omega,
\end{cases}
$$

(1.2)

where $\langle \cdot, \cdot \rangle$ is the inner product on $\mathbb{H}^n$ induced by the hyperbolic metric, $d$ the hyperbolic distance, $\vec{v}$ the unit outward normal vector along the boundary $\partial \Omega$ (we will also use the notation $\partial_\nu u$ for $\langle \nabla u, \vec{v} \rangle$), $\alpha$ a non-positive constant.

The function $f$ will be subject to the following assumptions:

$f$ is Lipschitz, (H1)
\( f \) is non-increasing on \([C - \epsilon, C]\) for some positive \( \epsilon \). \((H2)\)

Hypothesis \((H1)\) corresponds to the one in the BCN conjecture and is made all along the paper so it would not be mentioned in the statements of the results. Concerning Hypothesis \((H2)\), it will not be assumed in some results of Sect. 5, so we will precise when it is assumed. Moreover we notice that, if the fourth condition in \((1.2)\) is not empty, then \( f(C) = 0 \). Then the inequality \( u \leq C \) in \( \Omega \) can be deduce from this condition if \( f \) is non positive on \([C, +\infty)\). These hypotheses on \( f \) are similar to the ones appearing in [2,15]. It would be interesting to investigate the existence of nontrivial exterior domains in \( \mathbb{H}^n \) admitting a positive bounded solution as in the Euclidean case (cf. [18]).

The study of \( f \)-extremal domains in \( \mathbb{H}^n \) already appears in the work of Espinar and Mao [6]. They use the fact that the hyperbolic space can be compactified by its ideal boundary \( \partial_{\infty} \mathbb{H}^n \); so \( f \)-extremal domains can be studied in terms of their trace on \( \partial_{\infty} \mathbb{H}^n \), one of their results states that a \( f \)-extremal domain whose trace on \( \partial_{\infty} \mathbb{H}^n \) is at most one point is either a geodesic ball or a horoball (hypothesis \((H2)\) is not need in this result), this generalizes, to any \( f \), results by Molzon [13] and Sa Earp and Toubiana [19].

Here, our study looks at \( f \)-extremal domains whose trace on \( \partial_{\infty} \mathbb{H}^n \) is larger, for example we prove that a \( f \)-extremal domain whose complement is bounded is the complement of a geodesic ball. This result is similar to the one of Reichel [15] in the Euclidean case. We also give a characterization of the complement of a horoball.

We also prove that if the trace on \( \partial_{\infty} \mathbb{H}^n \) of \( \partial\Omega \) (with \( \Omega \) is a \( f \)-extremal domains) is some asymptotic equator (see Sect. 2 for a precise definition) then \( \Omega \) has to be invariant by a big subgroup of hyperbolic isometries. This result can be compared with the result of Berestycki, Caffarelli and Nirenberg concerning epigraphs.

As mentioned above, the geometry of \( f \)-extremal domains seems to imitate the geometry of constant mean curvature hypersurfaces. So it is interesting to compare our results with the ones obtained by do Carmo and Lawson [4] and Levitt and Rosenberg [12] where constant mean curvature hypersurfaces in \( \mathbb{H}^n \) are characterized by their trace on \( \partial_{\infty} \mathbb{H}^n \).

The paper is organized as follows. In Sect. 2, we recall some aspects of hyperbolic geometry and fix some notations used in the following sections. Section 3 is devoted to the study of exterior domains. In Sect. 4, we prove a result concerning the invariance by hyperbolic translations of \( f \)-extremal domains. In the last section, we study \( f \) extremal domains \( \Omega \) in \( \mathbb{H}^2 \) without hypothesis \((H2)\), the main point is to understand the asymptotic behaviour of \( \partial\Omega \) when it is connected.

2 Preliminaries about hyperbolic geometry

In this section, we will give an exosition of some aspects of the Hyperbolic Space for the reader convenience.

2.1 The hyperbolic space and its ideal boundary

The hyperbolic space \( \mathbb{H}^n \) \((n \geq 2)\) is (up to isometry) the only simply connected manifold of constant sectional curvature \(-1\). It is well known that the cut locus of any point on \( \mathbb{H}^n \) is empty, which implies that for any two points on \( \mathbb{H}^n \) there is a unique geodesic joining them. Therefore, the concept of geodesic convexity can be naturally defined for subsets of \( \mathbb{H}^n \).

If \((p, v)\) is an element of the unit tangent bundle \( U\mathbb{H}^n \), we define the half geodesic starting from \( p \) with initial speed \( v \) as the geodesic \( \gamma_v : [0, +\infty) \rightarrow \mathbb{H}^n \) with \( \gamma_v(0) = p \) and
the closed unit ball of half geodesics or on the set of unit vectors on such that the distance at infinity of we denote at infinity. Denote by the equivalence class of the corresponding geodesic \( γ(\cdot) \) or unit vector \( v \). It is called the end-point of \( γ \). If \( γ : \mathbb{R} \to \mathbb{H}^n \) is a unit speed geodesic line, we denote by \( γ(\cdot) \) the equivalence class of \( s \mapsto γ(−s) \).

It is well-known that for two asymptotic half geodesics \( γ_1 \) and \( γ_2 \) in \( \mathbb{H}^n \), the distances \( d(γ_1(t), γ_2(t)) \) and \( d(γ_2(t), γ_1) \) goes to zero as \( t \to +\infty \). Besides, for any \( x, y \in \partial_∞ \mathbb{H}^n \), there exists a unique oriented unit speed geodesic \( γ \) such that \( γ(0) = x \) and \( γ(\infty) = y \); this geodesic will be denoted by \( γ_2 \).

For any point \( p \in \mathbb{H}^n \), there exists a bijective correspondence between unit vectors at \( p \) and \( \partial_∞ \mathbb{H}^n \). In fact, for a point \( p \in \mathbb{H}^n \) and a point \( x \in \partial_∞ \mathbb{H}^n \), there exists a unique oriented unit speed geodesic \( γ \) such that \( γ(0) = p \) and \( γ(\infty) = x \). Equivalently, the unit vector \( v \) at the point \( p \) is mapped to the point at infinity \( v(\infty) \). Therefore, \( \partial_∞ \mathbb{H}^n \) is bijective to a unit sphere, i.e., \( \partial_∞ \mathbb{H}^n \equiv \mathbb{S}^{n−1} \). For \( p \in \mathbb{H}^n \) and \( x = \partial_∞ \mathbb{H}^n \), we denote by \( (px) \) the half geodesic starting at \( p \) with end-point \( x \).

Set \( \mathbb{H}^n = \mathbb{H}^n \cup \partial_∞ \mathbb{H}^n \). For a point \( p \in \mathbb{H}^n \), \( \mathcal{U} \) an open subset of the unit sphere of the tangent space \( T_p \mathbb{H}^n \) and \( r > 0 \), define

\[
T(\mathcal{U}, r) := \{ γ_v(t) \in \mathbb{H}^n \mid v \in \mathcal{U}, \ r < t ≤ +\infty \}.
\]

Then there is a unique topology \( \mathcal{T} \) on \( \mathbb{H}^n \) with the following properties: open subsets of \( \mathbb{H}^n \) are open subsets of \( \mathcal{T} \) and the sets \( T(\mathcal{U}, r) \) containing a point \( x = \partial_∞ \mathbb{H}^n \) form an open neighborhood basis at \( x \). This topology is called the ideal topology of \( \mathbb{H}^n \). Clearly, the ideal topology \( \mathcal{T} \) satisfies the following properties:

(A1) \( \mathcal{T} | \mathbb{H}^n \) coincides with the topology induced by the Riemannian distance;

(A2) for any \( p \in \mathbb{H}^n \) and any homeomorphism \( h : [0, 1] \to [0, +\infty] \), the function \( ϕ \), from the closed unit ball of \( T_p \mathbb{H}^n \) to \( \mathbb{H}^n \), given by \( ϕ(v) = \exp_p(h(∥v∥))v \) is a homeomorphism. Moreover, \( ϕ \) identifies \( \partial_∞ \mathbb{H}^n \) with the unit sphere;

(A3) for a point \( p \in \mathbb{H}^n \), the mapping \( v \to v(\infty) \) is a homeomorphism from the unit sphere of \( T_p \mathbb{H}^n \) onto \( \partial_∞ \mathbb{H}^n \).

(A4) with this topology, \( \mathbb{H}^n \) is a compactification of \( \mathbb{H}^n \) [11].

Using this topology, one can define the boundary at infinity of a subset \( A \) of \( \mathbb{H}^n \). Actually, we denote \( \overline{A}^∞ \) the closure in \( \mathbb{H}^n \) with the ideal topology. Then \( \partial_∞ A \) denotes the boundary at infinity of \( A \), that is, \( \partial_∞ A = \overline{A}^∞ \cap \partial_∞ \mathbb{H}^n \). Also, denote by \( \text{int}(\cdot) \) the interior of a given set of points.

2.2 Some models

Poincaré Ball model

There are several models for the hyperbolic space. Among them, the Poincaré Ball Model is very interesting to visualize the hyperbolic geometry.

The Poincaré Ball model is \((\mathbb{B}^n, g_{-1})\), where \( \mathbb{B}^n \) is the Euclidean unit ball in \( \mathbb{R}^n \) and \( g_{-1} \) is the Poincaré metric, which is given at a point \( x = (x_1, \ldots, x_n) \in \mathbb{B}^n \) by

\[
g_{-1}(\mathbf{x}, \mathbf{y}) = \sum_{i=1}^{n} \left( 1 - \sum_{j=1}^{n} x_j^2 \right)^{-1} x_i y_i.
\]
\[(g^{-1})_x := \frac{4}{(1 - |x|^2)^2} \left( \sum_{i=1}^{n} dx_i^2 \right), \quad (2.3)\]

Here \(|\cdot|\) denotes the Euclidean norm. It is well known that, in this model, the compactification \(\overline{\mathbb{H}^n}\) identified with the closed unit ball and its ideal boundary corresponds to

\[\partial_\infty \mathbb{H}^n = \partial \mathbb{B}^n = \mathbb{S}^{n-1}.\]

In this model, the geodesics are circle arcs (or segment) in \(\mathbb{B}^n\) orthogonal to \(\mathbb{S}^n\). As a consequence, totally geodesic submanifolds are given by spherical caps (or planar caps) meeting orthogonally the boundary of \(\mathbb{B}^n\). Actually, more generally, totally umbilical submanifolds of \(\mathbb{H}^n\) are given by the intersection of totally umbilical submanifolds in \(\mathbb{R}^n\) with \(\mathbb{B}^n\).

For example, one can observe that for any point \(p \in \mathbb{R}^n \setminus \mathbb{B}^n\) there exists a unique sphere \(S_p\), whose radius is given by \(r_p := |p|^2 - 1\), that meet orthogonally \(\partial \mathbb{B}^n\). Hence, \(P := S_p \cap \mathbb{B}^n\) is a totally geodesic hyperplane.

From (2.3), one can see that the isometry group of \(\mathbb{H}^n\) is given by the group of conformal transformations of \(\mathbb{R}^n\) that preserves \(\mathbb{B}^n\). In particular, linear isometries are isometries of the model. Euclidean reflections through hyperplanes containing the origin or inversions through spheres meeting orthogonally the boundary of \(\mathbb{B}^n\) are then reflections with respect to totally geodesic hyperplanes.

Before we continue, let us recall the relation between isometries of the Hyperbolic Space \(\mathbb{H}^n\), \(\text{Iso}(\mathbb{H}^n)\), and conformal diffeomorphisms on the sphere at infinity \(\mathbb{S}^{n-1}\), \(\text{Conf}(\mathbb{S}^{n-1})\). Using the Poincaré ball model, an isometry \(\mathcal{S} \in \text{Iso}(\mathbb{H}^n)\) induces a unique conformal diffeomorphism \(\Phi \in \text{Conf}(\mathbb{S}^{n-1})\); actually this map is bijective.

### Halfspace model

Another useful model is the Halfspace Model: it is \(\mathbb{R}^{n-1} \times (0, +\infty)\) endowed with the metric

\[\frac{1}{x^2_n} \left( \sum_{i=1}^{n} dx_i^2 \right), \quad (2.4)\]

Let \(s = (0, \ldots, 0, -1) \in \mathbb{R}^n\) then the map

\[\Phi : x \mapsto 2 \frac{x - s}{|x - s|^2} + s\]

is conformal and realizes a bijection from \(\mathbb{B}^n\) onto \(\mathbb{R}^{n-1} \times (0, +\infty)\). Actually \(\Phi\) is an isometry between the Poincaré ball model and the halfspace model. So properties of this model can be deduced from the preceding one using \(\Phi\). For example, the ideal boundary \(\partial_\infty \mathbb{H}^n\) is identified with \((\mathbb{R}^{n-1} \times \{0\}) \cup \{\infty\}\) where \(\infty\) is some point added in order to compactify \(\mathbb{R}^{n-1} \times \{0\}\). \(\infty\) correspond to \(s\) through \(\Phi\).

### 2.3 Submanifolds of \(\mathbb{H}^n\)

**Totally geodesic hyperplanes**

A totally geodesic hyperplane can be characterized by its boundary at infinity. If \(P\) is such a totally geodesic hyperplane, the set \(E = \partial_\infty P \subset \partial_\infty \mathbb{H}^n\) is called an asymptotic equator and for any asymptotic equator \(E\) there is a unique totally geodesic hyperplane \(P\) with \(\partial_\infty P = E\).
In the Poincaré ball model, the asymptotic equators are the hyperspheres of $\mathbb{S}^{n-1}$: that is, given any point $x \in \mathbb{S}^{n-1}$ and radius $r \in (0, \pi)$, the submanifold $\partial B_{\mathbb{S}^{n-1}}(x, r) \subset \mathbb{S}^{n-1}$ where $B_{\mathbb{S}^{n-1}}(x, r)$ is the geodesic ball in $\mathbb{S}^{n-1}$ centered at $x$ of radius $r \in (0, \pi)$. In particular, a classical equator centered at $x$, $E(x)$, appearing when $r = \pi/2$ is an asymptotic equator. When $x$ is the north pole $(0, \ldots, 0, 1)$, the hyperplane $P$ associated to $E(x)$ is given by

$$P(0) := \{(x_1, \ldots, x_n) \in \mathbb{B}^n : x_n = 0\}.$$  

The equidistant hypersurfaces at distance $c$ to some totally geodesic hyperplane $P$ are given by

$$P_c = \{\exp_p(c N(p)) \in \mathbb{H}^n, \ p \in P\},$$

where $\exp$ is the exponential map in $\mathbb{H}^n$ and $N$ is the unit normal along $P$. Each $P_c$ is totally umbilic with constant principal curvatures $-\tanh(c)$, that is,

$$II_{P_c} = - \tanh(c) I_{P_c},$$

where $I_{P_c}$ and $II_{P_c}$ denote the First and Second Fundamental Form respectively. Here the orientation for $P_c$ is the one given to be coherent with the normal $N$ on $P = P_0$. Actually, these equidistant hypersurfaces are the umbilic hypersurfaces of $\mathbb{H}^n$ with principal curvatures in the interval $(-1, 1)$.

Since $P_c$ is at a bounded distance from $P$, it implies that $\partial_\infty P_c = \partial_\infty P$.

**Horospheres**

Now, based on the above brief introduction, we can define Busemann functions and then horospheres. Given a unit vector $v$ in $T\mathbb{H}^n$, let $\gamma_v(t)$ be the oriented geodesic on $\mathbb{H}^n$ satisfying $\gamma'_v(0) = v$, then the Busemann function $B_v : \mathbb{H}^n \to \mathbb{R}$, associated to $v$, is defined by

$$B_v(p) = \lim_{t \to +\infty} d(p, \gamma_v(t)) - t.$$  

It is not difficult to see that this function has the following properties (cf. [5]):

- (B1) $B_v$ is a $C^2$ convex function on $\mathbb{H}^n$;
- (B2) the gradient $\nabla B_v(p)$ is the unique unit vector $-w$ at $p$ such that $v(\infty) = w(\infty)$;
- (B3) if $w$ is a unit vector such that $v(\infty) = w(\infty)$, then $B_v - B_w$ is a constant function on $\mathbb{H}^n$.

Given a unit vector $v$ in $T\mathbb{H}^n$, denote by $x$ the point $v(\infty) \in \partial_\infty \mathbb{H}^n$. The horospheres based or centered at $x$ are defined to be the *level sets* of the Busemann function $B_v$. By (B3), the horospheres at $x$ do not depend on the choice of $v$. The horoballs based at $x$ are defined to be the *sublevel sets* of the Busemann function $\{p \in \mathbb{H}^n \mid B_v(p) \leq t\}$.

The horospheres at $x$ give a foliation of $\mathbb{H}^n$, and by (B1), we know that each element of this foliation bounds a convex domain in $\mathbb{H}^n$ which is a horoball. By (B2), the intersection between a geodesic $\gamma$ and a horosphere based at $\gamma(+\infty)$ is always orthogonal.

The horospheres are the umbilic hypersurfaces of $\mathbb{H}^n$ with constant principal curvatures equal to 1 or $-1$ depending one the choice of orientation. Moreover, the induced metric on each horosphere is flat so they are isometric to $\mathbb{H}^{n-1}$.

In the Poincaré ball model, horospheres at $x \in \mathbb{S}^{n-1} \equiv \partial_\infty \mathbb{H}^n$ are given by spheres internally tangent to $\mathbb{S}^{n-1}$ at $x$. The tangency point $x$ is the unique point at infinity of the horosphere.

In the halfspace model, the horosphere based at $\infty$ are the horizontal hyperplanes $\{x_n = c\}$ for $c > 0$. 

\[ Springer \]
2.4 Isometries

Here, we will recall some important properties of the isometry group of \( \mathbb{H}^n \). We already know that this group acts as the group of conformal transformations of \( \mathbb{R}^n \) that preserves \( \mathbb{B}^n \). So one important fact is that \( \text{Iso}(\mathbb{H}^n) \) acts simply transitively on the space of orthonormal bases of \( T\mathbb{H}^n \); more precisely, if \( B_p \) and \( B_q \) are orthonormal bases of \( T_p\mathbb{H}^n \) and \( T_q\mathbb{H}^n \) respectively, then there is one and only one isometry of \( \mathbb{H}^n \) sending \( p \) to \( q \) and \( B_p \) to \( B_q \). This property tells that, in a model, we can often assume that we are in some standard position. For example, if \( P \) is a totally geodesic hyperplane, we can assume that it is \( \{x_n = 0\} \subset \mathbb{B}^n \) in the Poincaré ball model.

Reflections

Let \( P \) be a totally geodesic hyperplane of \( \mathbb{H}^n \) with unit normal \( N \). The isometry \( \mathcal{R}_P \) fixing points in \( P \) and sending \( N \) to \(-N \) is called the reflection through \( P \). We have \( \mathcal{R}_P \circ \mathcal{R}_P = \text{Id} \), here \( \text{Id} \) denotes the identity map. It is important to remark that the group \( \text{Iso}(\mathbb{H}^n) \) is generated by reflections.

Let \( \Omega \) be a (bounded or unbounded) connected domain in \( \mathbb{H}^n \) and \( \mathcal{R}_P \) be the reflection through \( P \). We say that \( \Omega \) is symmetric with respect to \( P \) if \( \mathcal{R}_P(\Omega) = \Omega \).

**Definition 2.1** Let \( P \) be totally geodesic hyperplane in \( \mathbb{H}^n \) and \( \Omega \) a domain symmetric with respect to \( P \). A \( C^2 \) function \( u : \Omega \rightarrow \mathbb{R} \) is **symmetric with respect to \( P \)** if

\[
u(p) = u(\mathcal{R}_P(p)) \text{ for all } p \in \Omega.\]

Rotations

Let \( \beta \) be a geodesic. An isometry that preserves the orientation and fix all points in \( \beta \) is called a rotation of axis \( \beta \). Actually, the set of rotations around \( \beta \) is a group isometric to \( SO(n-1)(\mathbb{R}) \) (the isomorphism is defined by looking at the action of a rotation on the orthogonal to \( \beta'(0) \) in \( T_{\beta(0)}\mathbb{H}^n \)). So we have a parametrization \( \{\mathcal{R}_\theta^\beta\}_{\theta \in SO(n-1)(\mathbb{R})} \) of the group of rotations around \( \beta \).

Moreover, one can check that any rotation around \( \beta \) can be written as the composition of an even number of reflections with respect to hyperplanes that contain \( \beta \).

If \( n \geq 3 \), we say that \( \Omega \) is axially symmetric with respect to \( \beta \) if \( \mathcal{R}_\theta^\beta(\Omega) = \Omega \) for all \( \theta \in SO(n-1)(\mathbb{R}) \). When \( n = 2 \), we say that \( \Omega \) is axially symmetric with respect to \( \beta \) if it is symmetric with respect to \( \beta \). Hence, we can define

**Definition 2.2** Let \( \beta \) be complete geodesic in \( \mathbb{H}^n \) and \( \Omega \) a domain axially symmetric with respect to \( \beta \). A \( C^2 \) function \( u : \Omega \rightarrow \mathbb{R} \) is **axially symmetric w.r.t. \( \beta \)** if

\[
u(p) = u(\mathcal{R}_\theta^\beta(p)) \text{ for all } \theta \in SO(n-1)(\mathbb{R}) \text{ and } p \in \Omega.\]

When \( n = 2 \), \( u \) is axially symmetric w.r.t \( \beta \) if \( u(p) = u(\mathcal{R}_\beta(p)) \) for all \( p \in \Omega \), where \( \mathcal{R}_\beta \in \text{Iso}(\mathbb{H}^2) \) is the reflection that leaves \( \beta \) invariant.

Hyperbolic translations

If \( \gamma : \mathbb{R} \rightarrow \mathbb{H}^n \) is a unit length geodesic and \( t \), the hyperbolic translation along \( \gamma \) at distance \( t \) is the isometry \( \mathcal{L}_\gamma^t \) such that \( \mathcal{L}_\gamma^t(\gamma(s)) = \gamma(s + t) \) and which acts by parallel transport along \( \gamma \) on the tangent space.
If \( \gamma \) is the geodesic joining the points \( x \) and \( y \) in \( \partial_\infty \mathbb{H}^n \), the conformal diffeomorphism induced by \( \mathcal{L}^\gamma \) on \( S^{n-1} = \partial_\infty \mathbb{H}^n \) fixes \( x \) and \( y \). Given any point \( p \in \mathbb{H}^n \setminus \gamma \), the orbit \( \{ \mathcal{L}^\gamma_t(p) \}_{t \in \mathbb{R}} \) is given by an equidistant curve \( \gamma_c \) to \( \gamma \) passing through \( p \), where \( c = \text{dist}(p, \gamma) \).

Let \( H_x(s) \) be the horosphere at \( x \) passing by \( \gamma(s) \), then \( \mathcal{L}^\gamma_t(\gamma(s)) = H_x(s + t) \).

Let \( P \subset \mathbb{H}^n \) be a totally geodesic hyperplane and denote \( E = \partial_\infty P \). Let \( P_c \) be the equidistant hypersurface to \( P \) at distance \( c \). Let \( P^+_c \) and \( P^-_c \) be the two connected components of \( \mathbb{H}^n \setminus P_c \). Note that for any complete geodesic \( \gamma \) contained in \( P \), i.e., \( \gamma : \mathbb{R} \to \mathbb{R}^n \), we have that \( \mathcal{L}^\gamma_t(P^+_c) = P^+_c \). In other words, \( \mathcal{L}^\gamma_t \) leaves \( P^+_c \) invariant (the same is true for \( P^-_c \)) for all \( \gamma \) contained in \( P \) and for all \( t \). This motivates:

**Definition 2.3** A \( C^2 \) function \( u : P^+_c \to \mathbb{R} \) is **translating invariant respect to \( P \)** if

\[
u(p) = u(L^\gamma_t(p)) \quad \text{for all } \gamma \subset P, \ t \in \mathbb{R} \text{ and } p \in P^+_c,
\]

here \( \gamma \) denotes a complete geodesic contained in \( P \).

Note that we could have considered the domain \( P^-_c \) in the above definition. Nevertheless, it is clear that the definition is analogous. Moreover, one can check that given any complete geodesic \( \gamma \) in \( \mathbb{H}^n \) and \( t \in \mathbb{R} \), there exists two totally geodesic hyperplanes \( P_1 \) and \( P_2 \), both orthogonal to \( \gamma \), whose associated hyperbolic reflections \( \mathcal{R}_1, \mathcal{R}_2 \in \text{Iso}(\mathbb{H}^n) \) satisfy

\[
\mathcal{L}^\gamma_t = \mathcal{R}_1 \circ \mathcal{R}_2.
\]

**Parabolic translations**

Given any point at infinity \( x \in \partial_\infty \mathbb{H}^n \), the **parabolic translations based at \( x \)** are the isometries of \( \mathbb{H}^n \) that acts as Euclidean translations on each horosphere \( H_x \) based at \( x \) for the induced Euclidean structure on \( H_x \). As a consequence the subgroup of parabolic translations is isomorphic to \( \mathbb{R}^{n-1} \); we have the parametrization \( \{ \mathcal{T}^x_v \}_{v \in \mathbb{R}^{n-1}} \). If \( \{ H_x(t) \}_{t \in \mathbb{R}} \) is the foliation of the horospheres based at \( x \) we have

\[
\mathcal{T}^x_v(H_x(t)) = H_x(t) \quad \text{for all } v \in \mathbb{R}^{n-1} \text{ and } t \in \mathbb{R}.
\]

If \( P_1 \) and \( P_2 \) are two totally geodesic hyperplanes such that \( \partial_\infty P_1 \cap \partial_\infty P_2 = \{ x \} \) and \( \mathcal{R}_1 \) and \( \mathcal{R}_2 \) are the reflections with respect to these hyperplanes then there is some \( v \in \mathbb{R}^{n-1} \) such that

\[
\mathcal{R}_1 \circ \mathcal{R}_2 = \mathcal{T}^x_v.
\]

Reciprocally, any parabolic translation \( \mathcal{T}^x_v \) can be decomposed in this way.

If \( H_x \) is some horosphere based at \( x \), we denote by \( H^+_x \) and \( H^-_x \) the two connected components of \( \mathbb{H}^n \setminus H_x \) such that \( \partial_\infty H^-_x = \{ x \} \) and \( \partial_\infty H^+_x = H^-_x \); \( H^-_x \) is the horoball bounded by \( H_x \). Then for any \( v \in \mathbb{R}^{n-1} \), we have \( \mathcal{T}^x_v(H^+_x) = H^+_x \) and \( \mathcal{T}^x_v(H^-_x) = H^-_x \).

**Definition 2.4** A \( C^2 \) function \( u : H^\pm_x \to \mathbb{R} \) is **horospherically symmetric** if

\[
u(p) = u(T^x_v(p)) \quad \text{for all } v \in \mathbb{R}^{n-1} \text{ and } p \in \Omega.
\]

### 3 Symmetry properties of exterior domains

#### 3.1 An important remark

In this subsection, we give an important result which is the cornerstone of the usage of the moving plane method in the next subsections.
In order to obtain symmetry conclusions, we must verify that the first PDE in the OEP (1.2) is invariant under reflections of $\mathbb{H}^n$. Since reflection generates $\text{Iso}(\mathbb{H}^n)$ by composition, it must be invariant under the group $\text{Iso}(\mathbb{H}^n)$. Invariant means that, if $u$ is a solution to (1.2) in $\Omega$, and $\mathcal{J} : \mathbb{H}^n \to \mathbb{H}^n$ an isometry, then $v(p) = u(\mathcal{J}(p))$ is a solution to (1.2) in $\tilde{\Omega} = \mathcal{J}^{-1}(\Omega)$.

Let $P$ be a totally geodesic hyperplane of $\mathbb{H}^n$ and $\mathcal{R}_P$ the reflection through $P$. Let $\Omega$ be a (bounded or unbounded) connected domain in $\mathbb{H}^n$. We denote by $\Omega^+$ the subset $\Omega \cap P^+$ (where $P^+$ is one connected component of $\mathbb{H}^n \setminus P$), that we assume to be nonempty, and denote by $\tilde{\Omega}^+$ its reflection through $P$, i.e. $\tilde{\Omega}^+ = \mathcal{R}_P(\Omega^+)$. Define a function $v(p)$ as follows

$$v(p) = u(\mathcal{R}(p)) \quad \text{for} \quad p \in \tilde{\Omega}^+. \tag{3.7}$$

For the function $v$, we can prove the following.

**Lemma 3.1** The function $v(p)$ defined by (3.7) satisfies the first PDE in the OEP (1.2).

### 3.2 A maximum principle

In order to apply the Moving Plane Method, we need the maximum principle at infinity given by the following lemma.

**Lemma 3.2** Let $\Omega$ be a connected domain in $\mathbb{H}^n$ and $E$ be an asymptotic equator. Let $c$ be a measurable function in $\Omega$ and $w \in C^2(\Omega)$ be a bounded below solution of

$$\Delta w + cw = 0$$

satisfying $\lim \inf w(p) \geq 0$ when $p$ converges to some point in $\partial \Omega \cup (\partial_\infty \Omega \setminus E)$.

If $c \leq 0$ in $\Omega$, then either $w \equiv 0$ or $w > 0$ in $\Omega$.

**Proof** It is enough to prove $w \geq 0$.

In the ball model, we can assume that $E = S^{n-1} \cap \{ x_n = 0 \}$. On $S^{n-1}$, we define $\lambda(x) = |x_n|^{-1/2}$ which is integrable on $S^{n-1}$. Let $u$ be the harmonic extension of $\lambda$ to $\mathbb{H}^n$. $u$ is then positive (actually $u \geq 1$) and $u(p) \to \infty$ as $p$ approaches $E$. Thus, for $t$ positive, we have $\lim \inf_{p \to \partial \Omega \cup \partial_\infty \Omega}(w + tu) \geq t$. Moreover

$$\Delta (w + tu) = -cw \leq -c(w + tu)$$

So the maximum principle implies that $w + tu \geq 0$ on $\Omega$. As it is true for any $t > 0$, $w \geq 0$. $\square$

### 3.3 Moving plane method and symmetries of domains

In this subsection, we apply the moving plane method to obtain a symmetry result for some $f$-extremal domains.

When $P$ is a totally geodesic hyperplane in $\mathbb{H}^n$ and $\gamma$ is a geodesic such that $\gamma(0) \in P$ and $\gamma$ is normal to $P$, we define a foliation of $\mathbb{H}^n$ in the following way: let $P(t)$ be the totally geodesic hyperplane passing through $\gamma(t)$ and normal to $\gamma$. With this construction, we have the following symmetry result.

**Theorem 3.3** Assume that $U$ is an open domain in $\mathbb{H}^n$ (non necessarily connected), with $C^2$ boundary, such that $\partial_\infty U \subset E$, where $E$ is an asymptotic equator at the boundary at
infinity $\partial_\infty \mathbb{H}^n$. Let $P$ be the totally geodesic hyperplane whose boundary at infinity is $E$, i.e., $\partial_\infty P = E$ and let $\gamma$ be a geodesic normal to $P$. Let $\{P(t)\}_{t \in \mathbb{R}}$ be the associated foliation.

Assume that the domain $\tilde{\Omega}_t^+ = \mathbb{H}^n \setminus U$ is connected and the OEP (1.2) has a solution $u \in C^2(\tilde{\Omega}_t^+)$, with $f$ satisfying (H2). Then, there is $t_0 \in \mathbb{R}$ such that $\tilde{\Omega}_t^+ = \mathbb{H}^n \setminus U$ is invariant by the reflection $R_{P(t_0)}$ i.e., $R_{P(t_0)}(\Omega) = \Omega$, and $u$ is also invariant under $R_{P(t_0)}$, that is, $u(p) = u(R_{P(t_0)}(p))$ for all $p \in \Omega$.

We first remark that if $\partial_\infty U \neq \emptyset$, $t_0$ is necessarily 0. The second remark is that, since $\Omega$ is connected and $\partial_\infty \Omega \subset E$, $\partial_\infty \Omega = \partial_\infty \mathbb{H}^n$.

**Proof** For $t \in \mathbb{R}$, we denote by $\mathcal{R}_t$ the reflection through $P(t)$. We also denote by $P^-(t)$ (resp. $P^+(t)$) the open halfspace bounded by $P(t)$ that contains $\{y(s), s < t\}$ (resp. $\{y(s), s > t\}$). We then introduce $U_t^- = P^-(t) \cap U$, $U_t^+ = P^+(t) \cap U$, $\Omega_t^- = P^-(t) \cap \Omega$ and $\Omega_t^+ = P^+(t) \cap \Omega$. We also define $\tilde{\Omega}_t^+ = \mathcal{R}_t(\Omega_t^+)$ in $P^-(t)$ and $\tilde{\Omega}_t^- = \mathcal{R}_t(U_t^-)$ (see Fig. 1).

On $\tilde{\Omega}_t^+$, the function $v_t = u \circ \mathcal{R}_t$ is defined and solves the PDE in (1.2). The first important fact is the following.

**Fact** Let $t$ be non positive. If $\tilde{\Omega}_t^+ \subset \Omega_t^-$, then

- either $v_t \leq u$ on $\tilde{\Omega}_t^+$,
- or $\{v_t > u\} \cap \{u < C - \epsilon\} \neq \emptyset$.

Moreover, in the first case, if $v_t(p) = u(p)$ at some point $p \in \tilde{\Omega}_t^+$ then $\tilde{\Omega}_t^+ = \Omega_t^-(\Omega$ is symmetric with respect to $P_t)$ and $v_t = u$ on $\tilde{\Omega}_t^+ = \Omega_t^-$.
So, let us assume $\tilde{\Omega}^+_t \subset \Omega^-$ and let $w_t$ be $u - v_t$ on $\tilde{\Omega}^+_t$. $v_t$ satisfies the following conditions

$$
\begin{cases}
\Delta v_t + f(v_t) = 0 & \text{in } \tilde{\Omega}^+_t, \\
v_t(p) = u_t(p) & \text{if } p \in \partial \tilde{\Omega}^+_t \cap P(t), \\
v_t(p) = 0 & \text{if } p \in \partial \tilde{\Omega}^+_t \cap P^-(t), \\
\langle \nabla v_t, \tilde{v} \rangle = \alpha & \text{on } \partial \tilde{\Omega}^+_t \cap P^-(t)
\end{cases}
$$

where $\partial \tilde{\Omega}^+_t \cap P^-(t)$ is included in $\mathcal{R}_t(\partial \Omega)$.

As a consequence, the function $w_t$ solves the PDE

$$
\Delta w_t + cw_t = 0
$$

where $c$ is defined by

$$
c(p) = \begin{cases}
-1 & \text{if } w_t(p) = 0 \\
\frac{f(u(p)) - f(v_t(p))}{u_t(p) - v_t(p)} & \text{if } w_t(p) \neq 0
\end{cases}
$$

By (H2) $f$ is non increasing on $[C - \epsilon, C]$, thus $c$ is a non positive function on $\{u \geq C - \epsilon\} \cap \{v_t \geq C - \epsilon\}$.

Let us assume that $\{v_t > u\} \cap \{u < C - \epsilon\} = \emptyset$ and define $V = \{u \geq C - \epsilon\} \cap \{v_t \geq C - \epsilon\}$. Since $u$ is bounded, $w_t$ is bounded too. Let $(p_n)$ be a sequence of points that converges to some point $q \in \partial V \cup \partial \infty V$. Let us study the behaviour of the sequence $(w_t(p_n))_{n \in \mathbb{N}}$.

First $q$ could be in $\partial V$, we have three possibilities

- $q \in \partial \tilde{\Omega}^+_t$, then $\lim w_t(p_n) = w_t(q) \geq 0$ and $w_t(q) = 0$ on $\partial \tilde{\Omega}^+_t \cap P(t)$ and $w_t(q) \geq 0$ on $\partial \tilde{\Omega}^+_t \cap P^-(t)$;
- $v_t(q) = C - \epsilon$ then $w_t(q) = u(q) - C + \epsilon \geq 0$;
- $u(q) = C - \epsilon$ then $w_t(q) \geq 0$ since $\{v_t > u\} \cap \{u < C - \epsilon\} = \emptyset$.

Let us assume now that $q \in \partial \infty V$. The first case is $\lim d(p_n, \mathcal{R}_t(\partial \Omega)) = +\infty$, this implies that $\lim d(p_n, \partial \Omega) = +\infty$ and $\lim d(\mathcal{R}_t(p_n), \partial \Omega) = +\infty$; thus, $u$ having $C$ as limit far from the boundary, $\lim w_t(p_n) = 0$. The last possibility is $d(p_n, \mathcal{R}_t(\partial \Omega))$ stays bounded. This case can only appear if $q \in \mathcal{R}_t(E)$. $\mathcal{R}_t(E)$ being an asymptotic equator, it does not matter in order to apply Lemma 3.2. Hence $w_t$ satisfies to the hypotheses of Lemma 3.2 and $w_t \geq 0$ in $V$. Since $w_t \geq 0$ on $\{v_t \leq C - \epsilon\} \cap \{u \geq C - \epsilon\}$, we have $v_t \leq u$ on $\tilde{\Omega}^+_t$.

In the first case, the equality case follows easily. This finishes the proof of the above fact.

We are now ready to apply the moving plane method. First since $\partial \infty U \subset E$, there is $t_0 \leq 0$ such that for any $t \leq t_0$, $P^-(t) \subset \Omega$ and $P^-(t) \subset \{u \geq C - \epsilon\}$. By the fact, this implies $w_t \geq 0$ on $\tilde{\Omega}^+_t$.

There is also $t_1$ the largest non positive number $t$ such that $P^-(s) \subset \Omega$ for any $s \leq t$. We assume for the moment that $t_1 < 0$.

Since $\partial \infty U \subset E$, for any $t < 0$, $P^-(t) \cap \overline{U}$ is compact. This implies that $P(t_1)$ is tangent to $\partial \Omega$. Since $\partial \Omega$ is $C^2$, there exists $\epsilon > 0$ such that $\tilde{U}^-_t \subset U_t^+$ (or $\tilde{\Omega}^+_t \subset \Omega^-$) and $\partial \Omega$ is not orthogonal to $P(t)$ for $t \in (t_1, t_1 + \epsilon)$.

So we can consider the $t \geq t_0$ such that $\tilde{\Omega}^+_t \subset \Omega^-$, $w_t \geq 0$ on $\tilde{\Omega}^+_t$ and $\partial \Omega$ is not orthogonal to $P(t)$. Looking at the first non positive time where such properties stop to be true, one of the following situations will happen:

(A) There exists $\bar{t} \in (t_0, 0)$ such that $\tilde{\Omega}^+_t \subset \Omega^-$ (and none of the geometric configurations (B) and (C) occurs), $w_t \geq 0$ and $w_t \geq 0$ ceases to be true for larger $t$.

(B) There exists $\bar{t} \in (t_1, 0)$ such that $\tilde{\Omega}^+_t$ is internally tangent to the boundary of $\Omega^-$ at some point $\bar{p}$ not in $P(\bar{t})$ and $\tilde{\Omega}^+_t \subset \Omega^+_t$ for all $t \in (-\infty, \bar{t})$. 

\(\text{Springer}\)
Theorem 3.4 Assume that $U$ is a bounded open domain in $\mathbb{H}^n$, with $C^2$ boundary, $\Omega = \mathbb{H}^n \setminus U$ is connected and on which the OEP (1.2) has a solution $u \in C^2(\overline{\Omega})$ with $f$ satisfying (H2). Then $U$ must be a geodesic ball and $u$ is radially symmetric.

This theorem is similar to Theorem 1 in [15] by Reichel.

Remark 3.5 In the above theorem, the function $u$ is then a function of the distance $s$ to some point $p_0 \in \mathbb{H}^n$. The PDE in (1.2) can then be written in terms of the variable $s$ as the ODE:

$$\partial_s^2 u + (n-1) \coth(s) \partial_s u + f(u) = 0.$$ 

Next, we will classify exterior domains $\Omega = \mathbb{H}^n \setminus U$ when $\partial_\infty U$ has only one point.

Theorem 3.6 Assume that $U$ is a domain in $\mathbb{H}^n$, with $C^2$ boundary and whose asymptotic boundary is a point $x_0 \in \partial_\infty \mathbb{H}^n$. Assume $\Omega = \mathbb{H}^n \setminus U$ is connected and on which the OEP (1.2) has a solution $u \in C^2(\overline{\Omega})$ with $f$ satisfying (H2). Then, $\Omega$ is the exterior of a horoball at $x_0$ and $u$ is horospherically symmetric.
This result can be compare to Theorem C in [19] by Sa Earp and Toubiana. We can also think to Theorem A in [4] by do Carmo and Lawson about the geometry of constant mean curvature hypersurfaces in $\mathbb{H}^n$.

**Proof** Let $P$ be a totally geodesic hyperplane such that $x_0 \in \partial_{\infty} P$ and apply Theorem 3.3 with $E = \partial_{\infty} P$. Since $\partial_{\infty} U \neq \emptyset$, the remark below Theorem 3.3 implies that $\Omega$ and $u$ are symmetric with respect to $P$.

Let $\mathcal{F}_v^{x_0}$ be a parabolic translation based at $x_0$ and $P_1$ and $P_2$ be two totally geodesic hyperplanes such that $\partial_{\infty} P_1 \cap \partial_{\infty} P_2 = \{x_0\}$ and $\mathcal{F}_v^{x_0} = \mathcal{F}_{P_1} \circ \mathcal{F}_{P_2}$. Since $\Omega$ and $u$ are invariant by $\mathcal{F}_{P_1}$ and $\mathcal{F}_{P_2}$ they are invariant by $\mathcal{F}_v^{x_0}$.

Thus if $p \in \partial \Omega$, $\mathcal{F}_v^{x_0}(p) \in \partial \Omega$ for any $v \in \mathbb{R}^{n-1}$ and each connected component of $\partial \Omega$ is a horosphere based at $x_0$. Now since $\Omega$ is connected and $\partial_{\infty} U = \{x_0\}$, $U$ is a horoball. Finally $u$ is horospherically symmetric (see [4] for similar arguments).

**Remark 3.7** In the above result, the function $u$ is then a function of the distance $s$ to some horospheres in $\mathbb{H}^n$. The PDE in (1.2) can then be written in term of the variable $s$ as the ODE:

$$\partial_s^2 u - (n-1) \partial_s u + f(u) = 0$$

Also, another consequence of Theorem 3.3 and Definition 2.2 is the following:

**Theorem 3.8** Assume that $U$ is a domain in $\mathbb{H}^n$, with boundary a $C^2$ hypersurface $\Sigma$ and whose asymptotic boundary consists in two distinct points $x, y \in \mathbb{S}^{n-1}, x \neq y$.

Assume $\Omega = \mathbb{H}^n \setminus \overline{U}$ is connected and on which the OEP (1.2) has a solution $u \in C^2(\overline{\Omega})$ with $f$ satisfying (H2). Then $\Omega$ is rotationally symmetric with respect to the axis given by the complete geodesic $\beta$ whose boundary at infinity is $\{x, y\}$, i.e., $\beta(\infty) = x$ and $\beta(-\infty) = y$.

In other words, $\Omega$ is invariant by the group of rotations in $\mathbb{H}^n$ fixing $\beta$. Moreover, $u$ is axially symmetric w.r.t. $\beta$.

## 4 Invariance of $f$-extremal domains

When $E$ is an asymptotic equator in $\partial_{\infty} \mathbb{H}^n$, the closure (in $\partial_{\infty} \mathbb{H}^n$) of each connected component of $\partial_{\infty} \mathbb{H}^n \setminus E$ is called an asymptotic hemisphere associated to $E$. If one asymptotic hemisphere $C$ is chosen and $P$ is the totally geodesic hyperplane with $\partial_{\infty} P = E$, we consider the equidistant hypersurfaces $P_t$ to $P$ (see Sect. 2.3 for the definition) and $P_t^+$ the connected component of $\mathbb{H}^n \setminus P_t$ with $C = \partial_{\infty} P_t^+$.

The next result mainly says that a $f$-extremal domain $\Omega$ such that $\partial_{\infty} \Omega$ is an asymptotic hemisphere is translating invariant with respect to some totally geodesic hyperplane.

**Theorem 4.1** Let $E$ be an asymptotic equator and $C$ an asymptotic hemisphere associated to $E$; we also denote by $P$ the totally geodesic hyperplane with $\partial_{\infty} P = E$. Let $\Omega$ be a connected domain with $C^2$ boundary $\Sigma$ such that $\partial_{\infty} \Sigma = E$ and $\partial_{\infty} \Omega = C$. Assume that the OEP (1.2) has a solution $u \in C^2(\overline{\Omega})$ with $f$ satisfying (H2).

Then $\Omega = P_t^+$ for some $c \in \mathbb{R}$ and $u$ is translating invariant respect to $P$.

Let us mention that this result has a great similarity with [4, Theorem 3.1] by do Carmo and Lawson dealing with constant mean curvature hypersurfaces.

**Proof** Let $\gamma$ be a geodesic normal to $P$ such that $\gamma(+\infty) \in C$ and $\{\mathcal{L}_t^\gamma\}_{t \in \mathbb{R}}$ the group of the hyperbolic translations along $\gamma$. 

$\odot$ Springer
For any $t \in \mathbb{R}$, we define $\Omega_t = \mathcal{L}_\gamma^t(\Omega)$ and $v_t = u \circ \mathcal{L}_\gamma^{-t}$ which is a function defined on $\Omega_t$. The first part of the proof consists in proving the following fact

**Fact** For any $t \leq 0$, $\Omega \subset \Omega_t$ and $u \leq v_t$ on $\overline{\Omega}$.

First we notice that for $t < 0$, there is $\bar{t}$ such that $\Omega \subset \Omega_\bar{t}$. Since $\mathcal{L}_\gamma^t$ is an isometry, $v_t$ satisfies:

$$\begin{cases}
\Delta v_t + f(v_t) = 0 & \text{in } \Omega_t, \\
v_t > 0 & \text{in } \Omega_t, \\
v_t = 0 & \text{on } \partial \Omega_t = \mathcal{L}_\gamma^t(\partial \Omega), \\
v_t(p) \to C & \text{uniformly as } d(p, \partial \Omega_t) \to +\infty \\
(\nabla v_t, \bar{v}) = \alpha & \text{on } \partial \Omega_t,
\end{cases} \quad (4.8)$$

Then the function $w_t = v_t - u$ solves the equation $\Delta w_t + cw_t = 0$ where $c$ is defined by

$$c(p) = \begin{cases} 
-1 & \text{if } v_t(p) = 0 \\
\frac{f(u(p)) - f(v_t(p))}{u(p) - v_t(p)} & \text{if } v_t(p) \neq 0
\end{cases}$$

By (H2) $f$ is non increasing on $[C - \epsilon, C]$, thus $c$ is a non positive function on $\{u \geq C - \epsilon\} \cap \{v_t \geq C - \epsilon\}$.

Let us assume that $\{u > v_t\} \cap \{v_t < C - \epsilon\} = \emptyset$ and define $V = \{u \geq C - \epsilon\} \cap \{v_t \geq C - \epsilon\}$. As in the proof of Theorem 3.3, lim inf $w_t(p_n)$ $\geq 0$ for any sequence $p_n$ converging to some point of $\partial V \cup (\partial_\infty V \setminus E)$. So Lemma 3.2 gives $w_t \geq 0$ and $v_t \geq u$ on $V$. Thus either $v_t \geq u$ in $\Omega$ or $\{v_t < C - \epsilon\} \cap \Omega$.

When $t$ is close to $-\infty$ we clearly have $\Omega \subset \Omega_t$ and $\{v_t < C - \epsilon\} \cap \Omega = \emptyset$ so $v_t \geq u$.

Hence there is $T < 0$ such that for any $t \leq T$, $\Omega \subset \Omega_t$ and $v_t \geq u$. Let $\tilde{t}$ be the largest non positive $T$ satisfying the above properties. Since for negative $t$, $\Omega_t$ has compact closure in $\mathbb{H}^n$, if $\tilde{t} < 0$, we have two possibilities

- either $\Omega \subset \Omega_{\tilde{t}}$, $u \leq v_t$ and $\partial \Omega$ and $\partial \Omega_{\tilde{t}}$ are tangent at some point $\tilde{p}$,
- or $\Omega \subset \Omega_t$ for $t \in [\tilde{t}, \tilde{t} + \delta)$ and $u \leq v_t$ ceases to be true at $\tilde{t}$.

In the first case, $u \leq v_t$ and both solutions of the PDE have the same Neumann boundary data at $\tilde{p}$. Thus Hopf’s boundary maximum principle implies that $u = v_t$ so $\Omega = \Omega_t$. i.e. $\tilde{t} = 0$. In the second case, we have two sequences $t_n \searrow \tilde{t}$ and $p_n \in \Omega$ such that $v_t(p_n) < u(p_n)$. Moreover we can assume $p_n \in \{v_t < C - \epsilon\}$. Since $\{v_t \leq C - \epsilon\} \cap \Omega$ is compact, we can assume $p_n \to \tilde{p} \in \{v_t \leq C - \epsilon\} \cap \Omega$ and $v_t(\tilde{p}) = u(\tilde{p})$. Since $\tilde{p} \notin \partial \Omega$, the maximum principle applied to $w_t$ gives $w_t \equiv 0$ which is possible only if $\tilde{t} = 0$. This finishes the proof of the fact.

The second step of the proof is to prove invariance with respect to hyperbolic translation along $P$. So let $\tilde{\gamma}$ be a geodesic in $P$ and $\{\mathcal{L}_{\tilde{\gamma}}^s\}_{s \in \mathbb{R}}$ the group of hyperbolic translations along $\tilde{\gamma}$. Then we denote by $\mathcal{L}_{\tilde{\gamma}}^{s,t}$ the isometry of $\mathbb{H}^n$ which is the composition $\mathcal{L}_{\tilde{\gamma}}^s \circ \mathcal{L}_\gamma^t$. Then we define $\Omega_{s,t} = \mathcal{L}_{\tilde{\gamma}}^{s,t}(\Omega)$ and $v_{s,t} = v \circ (\mathcal{L}_{\tilde{\gamma}}^{s,t})^{-1}$ which is defined on $\Omega_{s,t}$. Then we have the following fact

**Fact** For any $s \in \mathbb{R}$ and $t < 0$, $\Omega \subset \Omega_{s,t}$ and $u \leq v_{s,t}$ on $\overline{\Omega}$.
each connected component of $\partial_{\infty}\mathbb{H}^n \setminus E$ is stable by the group $\{L^s\}_{s \in \mathbb{R}}$ and the inclusion is true for $s = 0$.

To prove $\Omega \subset \Omega_{s,t}$, we fix $t < 0$ and we first remark that $\Omega \subset \Omega_{t} = \Omega_{0,t}$. So we can look at

$$s^- = \inf \{ S \leq 0 \mid \forall s \in [S, 0], \Omega \subset \Omega_{s,t} \} \quad \text{and} \quad s^+ = \sup \{ S \geq 0 \mid \forall s \in [0, S], \Omega \subset \Omega_{s,t} \}.$$

If $s^-$ is finite, as above, $\Omega_{s^-}$ and $\Omega$ are tangent somewhere and Hopf’s boundary maximum principle gives a contradiction. The same is true for $s^+$. This finishes the proof of the fact.

Now we can finish the proof of our theorem. Since $\Omega \subset \Omega_{s,t}$ for $s \in \mathbb{R}$ and $t < 0$, letting $t \to 0$ we get, $\Omega \subset \Omega_{s,0}$. Taking the image of this inclusion by $L^{-s}$ we get $\Omega_{s,0} \subset \Omega$. Thus $\Omega = \Omega_{s,0}$, $\Omega$ is translation invariant along $\gamma$ and then $P$ since $\gamma$ is arbitrary.

The same argument gives that $u = v_{s,0} = u \circ L^{-s}$; $u$ is translation invariant along $P$.

This invariance implies that each connected component of $\partial \Omega$ is an equidistant hypersurface $P_c$. Thus, since $\Omega$ is connected and $\partial_{\infty}\Omega = C$, we have $\Omega = P_c^+$ for some $c \in \mathbb{R}$.

\begin{remark}
In the above result, the function $u$ is then a function of the distance $s$ to some hyperplane $P$ in $\mathbb{H}^n$. The PDE in (1.2) can then be written in term of the variable $s$ as the ODE:

$$\partial_s^2 u + (n - 1) \tanh(s) s \partial_s u + f(u) = 0.$$

We notice that some aspects of the study of this ODE and the ones appearing in Remarks 3.5 and 3.7 can be found in [3].

\end{remark}

\section{5 $f$-extremal domains in $\mathbb{H}^2$}

From now on in this section, we will focus on the two dimensional case, i.e., $\Omega \subset \mathbb{H}^2$.

More precisely, we consider an unbounded open connected domain $\Omega$ in $\mathbb{H}^2$ whose $C^2$ boundary has only one connected boundary component $\Gamma$. We also assume that the OEP (1.2) has a solution $u$ on $\Omega$. If $\Gamma$ is compact and hypothesis (H2) is assumed, Corollary 3.4 implies that $\Omega$ is the exterior of a geodesic ball and $u$ is radially symmetric. If $\Gamma$ is unbounded, then, in order to apply results of the preceding sections, we need to understand the asymptotic behavior of $\Gamma$ : what is $\partial_{\infty}\Gamma$?

We notice that, in Lemmas 5.1, 5.2 and 5.3 below, hypothesis (H2) is not assumed on $f$. As in Sect. 3, we use the moving plane method but only for compact parts of domains. So we do not need to assume any monotonicity for $f$. We refer to [17] for such use of the moving plane method.

If $p \in \Gamma$, let us denote by $G(p)$ the endpoint in $\partial_{\infty}\mathbb{H}^2$ of the inward normal half-geodesic line to $\Gamma = \partial\Omega$ at $p$. We recall that $(pG(p))$ denotes the half-geodesic line starting at $p \in \mathbb{H}^n$ and ending at $G(p) \in \partial_{\infty}\mathbb{H}^n$.

The first step of our study of $\partial_{\infty}\Gamma$ is given by the following lemma which is similar to [17, Lemma 2.4].

\begin{lemma}
Let $\Omega$ be as above and $p \in \Gamma$. The half-geodesic line $(pG(p))$ is inside $\Omega$.
\end{lemma}

\begin{proof}
Same as in [17]
\end{proof}

The consequence of this property is that $G(p) \in \partial_{\infty}\Omega$. Actually we can say more, we have the following lemma.
Lemma 5.2 Let $\Omega$ be as above and $p \in \Gamma$. Then, either $G(p) \notin \partial_\infty \Gamma$ or $\Omega$ is a horodisk.

Proof Let us assume that $G(p) \in \partial_\infty \Gamma$. Using the half-space model for $\mathbb{H}^2 = \{(x, y) \in \mathbb{R} \times (0, +\infty)\}$, we can assume that $p = (0, 1)$ and $G(p) = \infty$, i.e., $\Gamma$ is horizontal at $p$. $\Gamma \setminus \{p\}$ has two connected components that we denote by $\Gamma_l$ and $\Gamma_r$ which, near $p$, lies respectively in $\{x > 0\}$ and $\{x < 0\}$. Moreover, we can assume that $\infty \in \partial_\infty \Gamma$. This means that, for any $R > 0$, there are points in $\Gamma_l$ outside the halfdisk $\{(x, y) \in \mathbb{R} \times (0, +\infty) : x^2 + y^2 \leq R^2\}$.

Let $\Omega_{l,R}$ be the connected component of $\Omega \setminus \{(pG(p)) \cap \{(x, y) \in \mathbb{R} \times (0, +\infty) : x^2 + y^2 \leq R^2\}\}$ with $p$ and a part of $\Gamma_l$ in its closure (the connected component that lies in $(x > 0)$ near $p$). Let $D_l$ be the half-disk $D_l = \{(x, y) \in \mathbb{R} \times (0, +\infty) : (x-t)^2 + y^2 \leq t^2\}$. First, we see that, since $\Gamma_l$ has points outside $\{(x, y) \in \mathbb{R} \times (0, +\infty) : x^2 + y^2 \leq 4R^2\}$, for any $0 < t \leq R$, $\Omega_{2R,t} = D_l \cap \Omega_{l,2R}$ is bounded and empty if $t$ is sufficiently small (see Fig. 2).

So now we can do Alexandrov reflection for the subsets $\Omega_{2R,t}$ for $t \leq R$, we symmetrize $\Omega_{2R,t}$ with respect to $\partial D_l$, which is a geodesic of $\mathbb{H}^2$ and we get $\tilde{\Omega}_{2R,t}$. On $\tilde{\Omega}_{2R,t}$, there is the symmetrized solution $\tilde{u}_{2R,t}$. We fix $R$ and let $t$ move from 0 to $R$. When $t$ is small $\Omega_{2R,t} \subset \Omega$ and $\tilde{u}_{2R,t}$ is below $u$. If there is a first contact between $\tilde{u}_{2R,t}$ and $u$ for $t \leq R$, we get a symmetry for $\Omega$ and $\tilde{\Omega}$ is bounded, which is a contradiction.

So we have $\tilde{\Omega}_{2R,t} \subset \Omega$ and $\tilde{u}_{2R,t} \leq u$ for any $t \leq R$. Thus $\tilde{u}_{2R,R} \leq u$ on $\tilde{\Omega}_{2R,R}$ for any $R > 0$. Letting $R$ goes to $+\infty$ we get that $\Omega$ and $\tilde{\Omega}$ are symmetric with respect to $\{x = 0\}$.

If $(x, y) \in \mathbb{R}^2$, we denote $(x, y) = (-x, y)$. Let $q$ be a point in $\Gamma$ close to $p$; we have $G(q) = \ast \ast G(q)$. Because of Lemma 5.1, the geodesic half-lines $(qG(q))$ and $(\ast qG(\ast q))$ do not intersect $\Gamma$. Joining this two geodesic half-lines by the piece of arc in $\Gamma$ between $q$ and $\ast q$, we get a proper curve in $\mathbb{R} \times [0, \infty)$ that does not cross $\Gamma$. If $G(q) \neq \infty$, this implies that $\Gamma$ stays far away from $\infty$ (see Fig. 3). As we assume that $\infty \in \partial_\infty \Gamma$, we can conclude that $G(q) = \infty$ for $q$ close to $p$. So the set $\{q \in \Gamma : G(q) = \infty\}$ is open and closed in $\Gamma$ and $G(q) = \infty$ for any $q$ in $\Gamma$ and $\Omega$ is a horodisk.

The preceding lemma allows us to control the asymptotic behaviour of $\Gamma$.

Lemma 5.3 $\partial_\infty \Gamma$ is made of at most two points.

Proof Let $p$ be a point in $\Gamma$, $\Gamma \setminus \{p\}$ has two connected components $\Gamma_1$ and $\Gamma_2$ and both $\partial_\infty \Gamma_1$ and $\partial_\infty \Gamma_2$ contain at least one point. We want to prove that both are made of only one point.
From Lemma 5.2 we know that \( \partial_\infty \Gamma \neq \partial_\infty \mathbb{H}^2 \) (either \( G(p) \in \partial_\infty \mathbb{H}^2 \setminus \partial_\infty \Gamma \) or \( \Omega \) is a horodisk and \( \partial_\infty \mathbb{H}^2 \) is made of one point). Besides \( \partial_\infty \Gamma \) are both intervals of \( \partial_\infty \mathbb{H}^2 \).

Let us assume that \( \partial_\infty \Gamma \) is not reduced to one point. So, in the half-space model, we can assume that \( \infty \notin \partial_\infty \Gamma \), \( \partial_\infty \Gamma \) is an interval that contains \([-1, 1] \times \{0\}\) and the geodesic \( \{x = 0\} \) is transverse to \( \Gamma \). We parametrized \( \Gamma \) by arc-length on \( \mathbb{R}_+^* \) and denote by \((x_{\Gamma_1}, y_{\Gamma_1})\) the parametrization. Because of the hypothesis on \( \Gamma \), there is an increasing sequence \( (s_n) \) such that \( \{s_n\}_{n \in \mathbb{N}} = x_{\Gamma_1}^{-1}(0) \). We then have \( y_{\Gamma_1}(s_n) \to 0 \) and the inward unit normal to \( \Gamma_1 \) points downward at \((x_{\Gamma_1}, y_{\Gamma_1})(s_n)\) when \( n \) is even or \( n \) is odd (depending on the unit normal at \((x_{\Gamma_1}, y_{\Gamma_1})(s_0)\) (see Fig. 4). Let us assume that it is the case when \( n \) is even. Choose \( k \) large so that \( y_{\Gamma_1}(s_{2k}) < 1 \), then \( G((x_{\Gamma_1}, y_{\Gamma_1})(s_{2k})) \in [-1, 1] \times \{0\} \subset \partial_\infty \Gamma \) which is a contradiction with Lemma 5.2. \( \square \)

Using this asymptotic behavior and assuming \( (H2) \), we can conclude:

**Theorem 5.4** (BCN-Conjecture in \( \mathbb{H}^2 \)) Let \( \Omega \subset \mathbb{H}^2 \) be a connected domain with \( C^2 \) boundary and such that \( \mathbb{H}^2 \setminus \overline{\Omega} \) is connected. If there exists a function \( u \in C^2(\Omega) \) that solves the OEP (1.2) with \( f \) satisfying \( (H2) \), then \( \partial \Omega \) has constant curvature.

More precisely, \( \Omega \) must be either

- a geodesic disk or the complement of a geodesic disk or,
• a horodisk or the complement of a horodisk or,
• a half-space determined by a complete equidistant curve, i.e. a complete curve of constant geodesic curvature $k_g \in [0, 1)$.

Moreover, in each case, $u$ is invariant by the isometries fixing $\Omega$.

**Proof** If $\partial \Omega$ is compact, then either $\Omega$ is compact and is a disk [6, Theorem 3.3] or $\Omega$ is unbounded and is the exterior of a disk by Theorem 3.4. In both cases, $u$ is radially symmetric.

If $\partial \Omega$ is not bounded, Lemma 5.3 implies that $\partial_\infty(\partial \Omega) = \{a\}$ or $\partial_\infty(\partial \Omega) = \{a, b\} \subset \partial_\infty \mathbb{H}^2$. In the first case, either $\partial_\infty \Omega = \{a\}$ and $\Omega$ is a horodisk [6, Theorem 3.8] or $\partial_\infty(\mathbb{H}^2 \setminus \Omega) = \{a\}$ and $\Omega$ is the complement of a horodisk by Theorem 3.6. In both cases, $u$ is invariant by parabolic isometries that fix $a$. If $\partial_\infty(\partial \Omega) = \{a, b\}$, Theorem 4.1 implies that $\Omega$ is a a half-space determined by a complete equidistant curve and $u$ is invariant by hyperbolic translations along the complete geodesic joining $a, b \in \partial_\infty \mathbb{H}^2$. □
