were 70.97% (95% CI 58.05%–81.80%) and 56.32% (95% CI 45.26%–66.94%) respectively. While for FluoroSpot, the AUROC was 0.906 (95 CI 0.856–0.957), the sensitivity and specificity of differentiating ATB from LTBI were 80.65% (95% CI 68.63%–89.58%) and 88.51% (95% CI 79.88%–94.35%) respectively.

**Conclusion.** Compared with T-SPOT.TB, the IFN-γ/IL-2/TNF-α-fluorospot assay may be helpful to distinguish ATB from LTBI, and the results need to be verified by large sample prospective cohort study.

**1406. Hepatitis B and C Prevalence in Patients with Active and Latent Tuberculosis in an Ethnically Diverse Area of London, UK**

Amedine Durut, MBBS BA (Hons)1; Emma Thorley, MBBS BA (Hons)1; Ayolola Eni-Oltra, n/a2; Oshi Sikdar, BSc3; Padmasayee Pappineni, MBChB4; London North West University Healthcare NHS Trust, London, England, United Kingdom; Imperial College London, London, England, United Kingdom

**Session:** P-80. Tuberculosis and other Mycobacterial Infections

**Background.** North West London has one of the highest tuberculosis (TB) rates in the UK, at 24.8 per 10,000. The UK prevalence of hepatitis B virus (HBV) is 0.1–0.5% and for hepatitis C virus (HCV) is 0.5–1%. Chronic infection with HBV or HCV can lead to an increased risk of adverse treatment outcomes, such as drug-induced liver injury (DILI) in patients with active or latent TB. National guidelines recommend routinely screening for HBV/HCV prior to initiating TB treatment. Our objectives were to (1) evaluate the HBV/HCV screening practice in local TB clinics, (2) establish the prevalence of HBV/HCV in patients receiving TB treatment.

**Methods.** Retrospective analysis of laboratory and medical records of patients treated for active or latent TB identified from the London TB register and clinic records from 01/01/2018 to 31/12/2020 from London North West NHS Trust.

**Results.** 1409 patients received treatment for TB during the time period of interest; 574 (40.70%) had active disease and 835 (59.30%) had latent infection. 966/1409 (68.56%) were screened for HBV and HCV. 55.9% of the active TB group and 72.2% of the latent infection group were tested. 66 (6.8%) patients had isolated anti-HBC positivity, 22 (2.3%) were HBV surface antigen positive and 8 (0.8%) were HCV-antibody positive. HBV surface antigens were more prevalent in active TB patients: 9/321 (2.80%) with active TB versus 13/645 (2.02%) with latent TB. 36/321 (11.21%) active TB patients had HBV core antibodies compared to 30/645 (4.65%) latent TB patients (p < 0.001). Three patients started antiviral treatment following their viral hepatitis diagnosis (one with HBV, two with HCV).

**Conclusion.** The prevalence of chronic HBV in the study population was higher than the estimated UK prevalence. Fifteen diagnoses of hepatitis were new, allowing specialist referral for monitoring of fibrosis and development of hepatocellular carcinoma. Three patients required hepatitis treatment. 6.8% of patients were positive for anti-HBc and therefore identified as being at future risk of HBV reactivation if requiring immunosuppressive therapies. TB disproportionately affects marginalised communities; screening for viral hepatitis in TB clinic represents an opportunity to target these hard-to-reach groups to maximise the impact of public health interventions.

**1407. The Latent Tuberculosis Infection Cascade of Care during the COVID-19 Pandemic Response in a Mid-Sized US City**

Trevor M. Stanfliff, BS1; Lauren Houshell, BS1; Rinki Goswami, MD4; Serenity Millow, BA1; Gabrielle Cook, n/a2; Robin Knappmyer, RN3; Christa Easton, RN2; Jennifer Moorey, PhD3; Moises A. Haaman, MD, MS4; University of Cincinnati, Cincinnati, Ohio; 4Hamilton County Public Health, Cincinnati, Ohio

**Session:** P-80. Tuberculosis and other Mycobacterial Infections

**Background.** The COVID-19 pandemic response may unintentionally disrupt multiple public health services, including tuberculosis control programs. We aimed to assess the cascade of care of latent tuberculosis infection (LTBI) in an urban US city during the COVID-19 pandemic response.

**Methods.** We conducted a retrospective cohort study of adult patients who presented for LTBI evaluation at the Hamilton County Public Health Tuberculosis Clinic in Ohio between 2019 and 2020. We defined 01/2019 to 02/2020 as the pre-COVID-19 response period, and 04/2020 to 12/2020 as the COVID-19 pandemic response period. We reviewed electronic medical records and extracted sociodemographic information, medical history, and follow-up and treatment data to determine success within the LTBI cascade of care. Logistic regressions were used to assess factors associated with LTBI treatment acceptance and completion, adjusted by potential confounders and COVID-19 period.

**Results.** Data from 312 patients were included. There was a significant decrease in the number of monthly LTBI referrals (median, 18 vs. 8, p < 0.02) and LTBI evaluations (median, 17.5 vs. 7, p < 0.01) during COVID-19. There was a decrease in the proportion of referrals for LTBI testing (50% vs. 9%; p < 0.01), and an increase in LTBI diagnosis based on interferon-gamma release assay (IGRA; 30% vs. 49%; p < 0.01) during COVID-19. The proportion of people who were recommended LTBI treatment was similar before and during COVID-19 (76% vs. 81%, p = 0.41), as well as the LTBI treatment acceptance rates (56% vs. 64%, p = 0.26), and LTBI treatment completion rates (65% vs. 63%, p = 0.85). In a multivariate analysis, LTBI treatment acceptance was associated with Hispanic ethnicity, younger age, male sex, IGRA use, no comorbidities, and non-healthcare occupation, independent of COVID-19 period. LTBI treatment completion was associated with taking a rifampin-containing regimen, independent of COVID-19 period.

**Conclusion.** We observed a significant decline in the number of monthly LTBI referrals and evaluations during COVID-19. Our findings indicate an unintended negative impact of the COVID-19 response in LTBI screening efforts in our region. LTBI treatment acceptance and completion rates were not affected during COVID-19.

**Session:** P-80. Tuberculosis and other Mycobacterial Infections

**Background.** Nontuberculous mycobacteria (NTM) cause pulmonary (PNTM) disease and extrapolmonary (ENTM) disease. NTM infections are difficult to diagnose and treat; environmental exposures occur in both healthcare and community settings. Few population-based studies describe NTM disease epidemiology. Current data indicate PNTM disease and ENTM skin and soft tissue infections are increasing. We describe findings from a multi-site pilot of population-based NTM surveillance.
