The universal Euler characteristic of $V$-manifolds

S.M. Gusein-Zade †  I. Luengo ‡  A. Melle-Hernández §

Abstract

The Euler characteristic is the only additive topological invariant for spaces of certain sort, in particular, for manifolds with some finiteness properties. A generalization of the notion of a manifold is the notion of a $V$-manifold. Here we discuss a universal additive topological invariant of $V$-manifolds: the universal Euler characteristic. It takes values in the ring generated (as a $\mathbb{Z}$-module) by isomorphism classes of finite groups. We also consider the universal Euler characteristic on the class of locally closed equivariant unions of cells in equivariant CW-complexes. We show that it is a universal additive invariant satisfying a certain “induction relation”. We give Macdonald type equations for the universal Euler characteristic for $V$-manifolds and for cell complexes of the described type.

1 Introduction

The Euler characteristic $\chi(\cdot)$ (defined as the alternating sum of the ranks of the cohomology groups with compact support) is the only additive topological invariant for spaces of certain sort: see, e. g., [20], see also [8, Proposition 2]. In particular, the Euler characteristic is the only additive invariant of manifolds with some finiteness properties: see below. This property has some generalizations. For example, the equivariant Euler characteristic with values in the Burnside ring $A(G)$ of a finite group $G$ is the only additive topological invariant of spaces with $G$-actions (see, e. g., [8]).

A generalization of the notion of a manifold is the notion of a $V$-manifold (that is of a (real) orbifold: locally defined as the quotient of a manifold by a finite group action) introduced initially in [16]. There are a number of additive invariants defined for $V$-manifolds, e. g., the Euler–Satake characteristic: [17], the orbifold Euler characteristic: [3], [7], [1], [13], the higher order (orbifold) Euler characteristics: [2], [13], the $\Gamma$–Euler–Satake characteristic: [7].

Here we discuss the universal additive topological invariant $\chi^\text{un}$ of $V$-manifolds: a sort of a universal (topological) Euler characteristic for them. It takes values in the ring $\mathcal{R}$ generated (as a $\mathbb{Z}$-module) by isomorphism classes of finite groups.

We also consider the universal Euler characteristic $\chi^\text{un}$ on the Grothendieck ring $K^\text{rig}_{\text{Gr}}(\text{Var}_\mathbb{C})$ of quasi-projective varieties with finite groups actions ([12]) and on the class of equivariant cell complexes: locally closed unions of cells in equivariant CW-complexes in the sense of [19]. In the latter case we show that $\chi^\text{un}$ is a universal additive invariant satisfying a certain “induction relation”.

The classical Euler characteristic satisfies the Macdonald equation for the generating series of the Euler characteristics of the symmetric powers of a topological space:

$$1 + \sum_{n=1}^{\infty} \chi(S^n X) \cdot t^n = (1 - t)^{-\chi(X)}.$$ 

Also one has a Macdonald type equation for the Euler characteristics of the configuration spaces of points on $X$. Let $M_n X = (X^n \setminus \Delta)/S_n$ be the configuration space of (unordered) $n$-tuples of points in $X$ ($\Delta$ is the big diagonal in the Cartesian power in $X^n$ consisting of points $\bar{x} = (x_1, \ldots, x_n) \in$
with at least two coinciding components). One has
\[ 1 + \sum_{n=1}^{\infty} \chi(M_nX) \cdot t^n = (1 + t)^{\chi(X)}. \]

Analogues of these equations for other (additive) invariants with values in rings different from the ring of integers (say, for the equivariant Euler characteristic or for the generalized (motivic) Euler characteristic of complex quasi-projective varieties) are formulated in terms of power structures over the rings of values: [Lemma 1], [10]. A power structure over a ring is closely related with (and defined by) a $\lambda$-ring structure on it. Analogues of these equations for the universal Euler characteristic are formulated in terms of different $\lambda$-ring structures on $R$. We discuss these $\lambda$-ring structures on $R$ and the corresponding power structures. We give Macdonald type equations for the universal Euler characteristic $\chi^{\text{un}}$ for $V$-manifolds and for equivariant cell complexes.

## 2 Euler characteristic of manifolds

The Euler characteristic is defined for manifolds with some finiteness properties. To fix a class of such manifolds, let us consider ($C^\infty$-) manifolds which are interiors of compact manifolds with boundaries. A submanifold of such a manifold is the interior of a (closed) submanifold in a manifold with boundary, that is of a submanifold transversal to the boundary. (We permit a submanifold to be of the same dimension as the manifold itself. In this case the submanifold is a connected component of the manifold.) In what follows we consider only manifolds from this class. Let $M$ be a manifold and let $N$ be a (closed) submanifold of $M$. One has the following additivity property of the Euler characteristic:
\[ \chi(M) = \chi(N) + \chi(M \setminus N). \]

(Pay attention that $M \setminus N$ is also a manifold from the described class.) One has the inverse statement.

**Proposition 1** Let $I$ be a topological invariant of manifolds which possesses the additivity property:
\[ I(M) = I(N) + I(M \setminus N) \]
for a submanifold $N \subset M$. Then $I(M) = \chi(M)a$, where $a = I(pt)$. 
Proof. First let us reduce the statement to the corresponding statement for cells, i. e., for manifolds diffeomorphic to open balls. For that we will cut a given $n$-dimensional manifold $M^n$ by submanifolds into pieces diffeomorphic to cells. A one-dimensional manifold is a (finite) union of open segments and circles and there is no problem to decompose it into cells. Assume that this is possible for manifolds of dimension less than $n$. Let $M$ be the interior of a manifold $\hat{M}$ with boundary and let $f : \hat{M} \to \mathbb{R}$ be a Morse function on $\hat{M}$ equal to zero on the boundary $\partial\hat{M}$ and positive on $M$. Let $0 < c_1 < c_2 < \ldots < c_r$ be the critical values of $f$ (and let $c_0 = 0$). Let $U_i$ be small open balls around the corresponding critical points $P_i$. The manifold $M$ is the union of the manifolds $M_i = f^{-1}((c_{i-1} + \varepsilon, c_i - \varepsilon))$, $M'_i = f^{-1}((c_i - \varepsilon, c_i + \varepsilon))$ and $N_{i\pm} = f^{-1}(c_i \pm \varepsilon)$ (we take $\varepsilon$ small enough). We have to cut these manifolds into cells (using submanifolds). For the manifolds $N_{i\pm}$ this is possible because of the assumption. The manifold $M_i$ is (diffeomorphic to) the cylinder over the manifold $N_{i-}$ and a method to cut $N_{i-}$ into cells (by submanifolds) can be extended to $M_i$ in an obvious way. The intersection $M'_i \cap U_i$ is diffeomorphic to a cell. The complement $M'_i \setminus U_i$ is (diffeomorphic to) the cylinder over $N_{i-} \setminus U_i$. A method to cut $N_{i-} \setminus U_i$ gives a method to cut $M'_i \cap U_i$. (Here we apply an obvious version of the procedure to $N_{i-} \setminus U_i$ which is a manifold with boundary.)

The additivity property permits to prove the statement for cells (open balls):

$$I(\sigma^k) = (-1)^k I(\text{pt}).$$

(1)

Assume that (1) is proved for cells of dimension less than $k$, in particular, $I(\sigma^{k-1}) = (-1)^{k-1} I(\text{pt})$. The ball $\sigma^k$ can be cut by a submanifold diffeomorphic to $\sigma^{k-1}$ into two manifolds diffeomorphic to $\sigma^k$. Therefore

$$I(\sigma^k) = 2I(\sigma^k) + I(\sigma^{k-1}),$$

what gives (1). □

3 V-manifolds (real orbifolds)

Let us give some definitions in a form appropriate for a discussion below.

For a $G$-space $X$, that is a topological space $X$ with a (left) $G$-action, and for an embedding $G < H$ ($G$ and $H$ are finite groups), let the induction
ind$^H_G X$ be the $H$-space defined as the quotient

$$\text{ind}^H_G X = H \times X / \sim,$$

where $(h_1, x_1) \sim (h_2, x_2)$ if (and only if) there exists $g \in G$ such that $x_1 = gx_2$, $h_1 = h_2g^{-1}$ (with an obvious $H$-action). As a topological space ind$^H_G X$ is the union of several ($|H|/|G|$) copies of $X$. If $X$ is, say, a $(C^\infty)$ manifold or a complex quasi-projective variety, the space ind$^H_G X$ is of the same type.

**Definition 1** An $(n$-dimensional) uniformizing system on a topological space $X$ is a quadriple $(U, \tilde{U}, G, \varphi)$, where $U$ is an open subset of $X$, $G$ is a finite group, $\tilde{U}$ is a smooth $(C^\infty)$ $n$-dimensional manifold with a $G$-action, and $\varphi$ is a map $\tilde{U} \to U$ such that $\varphi(gx) = \varphi(x)$ (that is $\varphi$ factorizes through a map $p_\varphi: \tilde{U}/G \to U$) and the corresponding map $p_\varphi$ is a homeomorphism.

**Remark.** In some cases one adds the condition that the fixed point set of each element of $G$ has codimension at least two in $\tilde{U}$. This restriction is not necessary in this paper and it is more convenient not to require it.

**Definition 2** Two uniformizing systems $(U', \tilde{U}', G', \varphi')$ and $(U'', \tilde{U}'', G'', \varphi'')$ on $X$ are equivalent if for any point $x \in U' \cap U''$ there exists a neighbourhood $U$ of $x$ in $U' \cap U''$, a group $G$ contained both in $G'$ and in $G''$ (that is with embeddings into $G'$ and into $G''$) and a uniformizing system $(U, \tilde{U}, G, \varphi)$ such that the $G'$-manifolds ind$^G_{G'} \tilde{U}$ and $(\varphi')^{-1}(U)$ are isomorphic over $U$ (that is by an isomorphism commuting with the projections to $U$) and the $G''$-manifolds ind$^G_{G''} \tilde{U}$ and $(\varphi'')^{-1}(U)$ are isomorphic over $U$ as well.

**Definition 3** A $(V$-manifold$)$ atlas on a topological space $X$ is a collection of $n$-dimensional uniformizing systems $\{(U_\alpha, \tilde{U}_\alpha, G_\alpha, \varphi_\alpha)\}$ on $X$ such that $\bigcup_\alpha U_\alpha = X$ and any two uniformizing systems from the collection are equivalent.

**Definition 4** Two atlases on $X$ are equivalent if their union is an atlas on $X$ as well.

**Definition 5** (see [10], [3]) An $n$-dimensional $V$-manifold $Q$ is a separable Hausdorff space $X = X_Q$ with an equivalence class of $n$-dimensional atlases on it.
One can define in a natural way the notion of a $V$-manifold with boundary: see [17], [3, Appendix]. In order to ensure that the topological characteristics discussed below are defined, one has to impose certain finiteness conditions on $V$-manifolds under consideration. We will assume that in what follows all $V$-manifolds are interiors of compact $V$-manifolds with boundaries. (For short we will call them tame.)

The universal Euler characteristic as well as other invariants discussed below can also be regarded as homomorphisms from the Grothendieck ring $K_{0}^{\mathrm{Gr}}(\text{Var}_{C})$ of finite group actions defined in [12]. The Grothendieck ring $K_{0}^{\mathrm{Gr}}(\text{Var}_{C})$ is the Abelian group generated by the classes $[(X,G)]$ of quasi-projective $G$-varieties for all finite groups $G$ modulo the relations

1) if $(X, G) \cong (X', G')$ (that is if there exist a group isomorphism $\alpha : G \rightarrow G'$ and an (algebraic) isomorphism $\psi : X \rightarrow X'$ such that $\psi(gx) = \alpha(g)\psi(x)$), then $[(X, G)] = [(X', G')]$;

2) if $Y$ is a Zariski closed $G$-subset of $X$, then $[(X, G)] = [(Y, G)] + [(X \setminus Y, G)]$;

3) if $G$ is a subgroup of a finite group $H$ and $X$ is a $G$-variety, then $[(X, G)] = [\text{ind}^{H}_{G}X, H]$.

The multiplication in $K_{0}^{\mathrm{Gr}}(\text{Var}_{C})$ is defined by the Cartesian product of the varieties and of the groups acting on them.

It is convenient to discuss some properties of the universal Euler characteristic in a purely topological setting. For that we will consider a sort of nice topological spaces with finite group actions. The notion of an equivariant $CW$-complex was introduced in [19]. An equivariant $CW$-complex with a finite group $G$ action is a $CW$-complex possessing, in particular, the following property: if $g\sigma = \sigma$ for a cell $\sigma$ of the complex, then $g\sigma$ is the identity transformation.

**Definition 6** An equivariant cell complex is an invariant locally closed union of cells in a finite equivariant (with respect to a finite group) $CW$-complex.

A quasi-projective $G$-variety or a (real) semialgebraic $G$-set ($G$ is a finite group) can be represented as an equivariant cell complex. For an equivariant cell complex its Euler characteristic, equivariant Euler characteristic, orbifold Euler characteristic, . . . are well defined: see below.
4 Additive invariants of $V$-manifolds

There are a number of additive invariants defined for $V$-manifolds. For a $G$-space $X$ ($G$ is a finite group) and for a point $x \in X$, let $G_x = \{g \in G : gx = x\}$ be the isotropy subgroup of $x$. For a subgroup $H \subset G$, let $X^H = \{x \in X : hx = x \text{ for all } h \in H\}$ be the fixed point set of the subgroup $H$ and let $X^{(H)} = \{x \in X : G_x = H\}$ be the subspace of points with the isotropy subgroup $H$ ($X^{(H)} \subset X^H$). For a conjugacy class $[H]$ of subgroups of $G$, let $X([H]) = \{x \in X : G_x \in [H]\}$. Let $\mathcal{G}$ be the set of the isomorphism classes of finite groups.

Let $Q$ be a (tame) $V$-manifold. For each point $x \in Q$ one associates the isotropy (sub)group $G_x$. For a finite group $G$, let $Q^{(G)} = \{x \in Q : G_x \cong G\}$. One can see that the $V$-manifold $Q^{(G)}$ is a global quotient (under an action of the group $G$). Moreover, its reduction is the usual ($C^\infty$-) manifold (with the action of the trivial group).

The Euler-Satake characteristic of $Q$ ([17]) is defined by

$$\chi^{ES}(Q) = \sum_{\{G\} \in \mathcal{G}} \frac{1}{|G|} \chi(Q^{(G)}). \quad (2)$$

The orbifold Euler characteristic (defined in, e. g., [1], [13]) can be defined for a $V$-manifold by

$$\chi^{\text{orb}}(Q) = \sum_{\{G\} \in \mathcal{G}} \chi^{\text{orb}}(G/G, G) \cdot \chi(Q^{(G)}),$$

where $\chi^{\text{orb}}(G/G, G)$ is the orbifold Euler characteristic of the one-point $G$-set $G/G$ (in the sense of [1], [13]). If all the isotropy groups of points of $Q$ are Abelian, one has

$$\chi^{\text{orb}}(Q) = \sum_{\{G\} \in \mathcal{G}} |G| \cdot \chi(Q^{(G)}).$$

The higher order orbifold Euler characteristics $\chi^{(k)}(X, G)$ of a $G$-space $(X, G)$ were defined in [2], [18]. For $k = 0, 1$, one has $\chi^{(0)}(X, G) = \chi(X/G)$, $\chi^{(1)}(X, G) = \chi^{\text{orb}}(X, G)$. (We follow the numbering used in [18].) For a $V$-manifold they can be defined by

$$\chi^{(k)}(Q) = \sum_{\{G\} \in \mathcal{G}} \chi^{(k)}(G/G, G) \cdot \chi(Q^{(G)}).$$
If all the isotropy groups of points of $Q$ are Abelian, one has
\[ \chi^{(k)}(Q) = \sum_{\{G\} \in G} |G|^k \cdot \chi(Q^{(G)}) . \]

One can see that the Euler-Satake characteristic \[2\] can be regarded as the Euler characteristic of order \((-1)\). This fits to the definition of the $\Gamma$-Euler-Satake characteristic $\chi^{ES}_\Gamma(Q)$ of a $V$-manifold for a group $\Gamma$ in \[7\]: for $\Gamma = \mathbb{Z}^{k+1}$ one gets the Euler characteristic of order $k$; for $\Gamma = \{1\}$ (i. e., $\Gamma = \mathbb{Z}^0$), one gets the Euler–Satake characteristic.

All these characteristics possess the additivity and the multiplicativity properties: if $Q'$ is a (closed) $V$-submanifold of a $V$-manifold $Q$, one has $\chi^*(Q) = \chi^*(Q') + \chi^*(Q \setminus Q')$; if $Q_1$ and $Q_2$ are $V$-manifolds, one has $\chi^*(Q_1 \times Q_2) = \chi^*(Q_1) \cdot \chi^*(Q_2)$. (Here $\chi^*$ means $\chi^{ES}$, $\chi^{orb}$, \ldots)

All these invariants can be defined on the Grothendieck ring $K^{Gr}_0(\text{Var}_\mathbb{C})$ of quasi-projective varieties with finite groups actions so that they are ring homomorphism from $K^{Gr}_0(\text{Var}_\mathbb{C})$ to the ring $\mathbb{Z}$ of integers. Moreover, all of them can be defined for equivariant cell complexes. For example, if $X$ is an equivariant cell complex with an action of a finite group $G$, then its orbifold Euler characteristic can be defined by the equation
\[ \chi^{orb}(X, G) = \frac{1}{|G|} \sum_{\langle g, h \rangle \in G \times G, yh = hg} \chi(X^{\langle g, h \rangle}) , \]
where $\langle g, h \rangle$ is the subgroup of $G$ generated by $g$ and $h$, or by the equation
\[ \chi^{orb}(X, G) = \sum_{[H] \in \text{conjsub } G} \chi(X^{[H]})/G) \chi^{orb}(G/H, G) , \]
where conjsub $G$ is the set of conjugacy classes of subgroups of $G$.

5 The universal Euler characteristic

Let $\mathcal{G}$ be the set of all isomorphisms classes of finite groups and let $\mathcal{R}$ be be the free Abelian group generated by the elements $T^G$ correspondig to the classes $\{G\} \in \mathcal{R}$. We will write an element of $\mathcal{R}$ as a finite sum of the form $\sum_{\{G\} \in G} a_G T^G$, where $a_G \in \mathbb{Z}$. One has a natural multiplication on $\mathcal{R}$ defined by $T^G \cdot T^G' = T^{G \times G'}$. Thus $\mathcal{R}$ is a ring. Accroding to the Krull-Schmidt theorem each finite group has a unique representation as the product
of indecomposable finite groups. Let $G_{\text{ind}}$ be the set of the isomorphisms classes of indecomposable finite groups. The Krull-Schmidt theorem implies that $R$ is the polynomial ring $\mathbb{Z}[T_G]$ in the variables $T_G$ corresponding to (the isomorphisms classes of) the indecomposable finite groups. (If a finite group $G$ has the decomposition $G \cong \prod_{i=1}^{r} G(i)$ with indecomposable $G(i)$, one has $T_G = \prod_{i=1}^{r} T_{G(i)}$.)

**Definition 7** The universal Euler characteristic of (tame) $V$-manifold $Q$ is defined by

$$\chi^{\text{un}}(Q) = \sum_{\{G\} \in G} \chi(Q^{(G)}) T_G^G \in R.$$  

One can see that $\chi^{\text{un}}$ is an additive and multiplicative invariant of $V$-manifolds.

Another interpretation of the ring $R$ is the following one: it is the subring of the Grothendieck ring $K_{fGr}^0(\text{Var}_C)$ of quasi-projective varieties with finite groups actions generated by the finite sets, i.e., by zero-dimensional varieties. In terms of the description/definition of the Grothendieck ring $K_{fGr}^0(\text{Var}_C)$ in [12], an element $a = \sum_{\{G\} \in G} a_G T_G^G \in R$ can be represented by the (virtual) set consisting of $\sum_{G \in G} a_G$ points so that on $a_G$ of them ($a_G$ may be negative) one has the trivial action of the group $G$. In terms of the description given above, an element $a$ can be represented by a pair $(X, G^*)$, where $G^*$ is a group containing all the groups $G$ with $a_G \neq 0$ and $X$ is the union over $\{G\} \in G$ of the (finite) sets which consists of $a_G$ copies of $G^*/G$ with the natural $G^*$-action.

The universal Euler characteristic $\chi^{\text{un}}(\bullet)$ can be defined for elements of the Grothendieck ring $K_{fGr}^0(\text{Var}_C)$ of quasi-projective varieties with finite groups actions. Moreover it can be defined for equivariant cell complexes. For an equivariant cell complex $X$ with an action of a finite group $G$, $\chi^{\text{un}}(X, G)$ can be defined by the equation

$$\chi^{\text{un}}(X, G) = \sum_{[H] \in \text{conjsub } G} \chi(X^{([H])/G}) T^H.$$  

In orther terms it can be defined in the following way. The set $\Sigma_k$ of cells of dimesion $k$ in $X$ is a finite set with a $G$-action. Then

$$\chi^{\text{un}}(X, G) = \sum_k (-1)^k [\Sigma_k, G] \in R.$$  

In orther terms it can be defined in the following way. The set $\Sigma_k$ of cells of dimesion $k$ in $X$ is a finite set with a $G$-action. Then

$$\chi^{\text{un}}(X, G) = \sum_k (-1)^k [\Sigma_k, G] \in R.$$
One can see that the universal Euler characteristic of equivariant cell complexes possesses the following properties:

1) additivity: if \((Y; G)\) is a closed \(G\)-invariant subcomplex of \((X, G)\), then
   \[ \chi^\text{un}(X, G) = \chi^\text{un}(Y, G) + \chi^\text{un}(X \setminus Y, G) ; \]

2) multiplicativity: if \((X', G')\) and \((X'', G'')\) are two equivariant cell complexes, then
   \[ \chi^\text{un}(X' \times X'', G' \times G'') = \chi^\text{un}(X', G') \cdot \chi^\text{un}(X'', G'') ; \]

3) the induction relation: if \(G\) is a subgroup of \(H\), then
   \[ \chi^\text{un}(\text{ind}^H_G X, H) = \chi^\text{un}(X, G). \]

The relations 1) and 3) permit to define the universal Euler characteristic \(\chi^\text{un}\) as a function on the Grothendieck ring \(K^\text{fGr}\) (with values in \(R\)). The relations 1) and 2) mean that it is a ring homomorphism to \(R\).

Let us give a statement which explains the word universal in the name of \(\chi^\text{un}\).

**Theorem 1** If \(I\) is an additive invariant of (tame) \(V\)-manifolds with values in an Abelian group \(R\), then there exists a unique homomorphism of Abelian groups \(r : R \to R\) such that \(I(\bullet) = r(\chi^\text{un}(\bullet))\). If \(R\) is a ring and \(I\) multiplicative, then \(r\) is a ring homomorphism.

**Proof.** Let \(Q\) be a tame \(V\)-manifold. For a finite group (or rather for an isomorphism class of finite groups) \(G\), let \(Q^{(G)}\) be the set of points \(x \in X_Q\) with isotropy group isomorphic to \(G\). The fact that \(Q\) is assumed to be tame implies that there are finitely many classes \(G\) such that \(Q^{(G)} \neq \emptyset\). \((Q^{(G)})\) is a non-closed \(V\)-submanifold of \(Q\) whose reduction is a usual \(C^\infty\)-manifold.

The set \(G\) of isomorphism classes of finite groups is a partially order set. Let \(G\) be a minimal element from \(G\) with \(Q^{(G)} \neq \emptyset\). By additivity one has \(I(Q) = I(Q^{(G)}) + I(Q \setminus Q^{(G)})\). Iterating this equation one gets \(I(Q) = \sum_{G \in G} I(Q^{(G)})\). Since \(Q^{(G)}\) is the usual \(C^\infty\)-manifold, due to Proposition \(\square\) one has \(I(Q^{(G)}) = \chi(Q^{(G)}) \tau_G\), with \(\tau_G = I(T^{(G)}) \in R\). One can see that the group homomorphism \(r : R \to R\) which sends the universal Euler characteristic \(\chi^\text{un}(\bullet)\) to \(I(\bullet)\) is defined by \(r(T^{(G)}) = \tau_G\).

The multiplicativity of \(r\), for \(I\) being multiplicative, is obvious. \(\square\)

One also has the following universality properties of \(\chi^\text{un}(\bullet)\) for equivariant cell complexes.
Theorem 2  Let \( I \) be an additive invariant of equivariant cell complexes with values in an Abelian group \( R \) posseing the induction property: \( I(\text{ind}^H_G X, H) = I(X, G) \) for finite groups \( G \subset H \). Then there exists a unique homomorphism of Abelian groups \( r : R \to R \) such that \( I(\cdot, \cdot)) = r(\chi(\cdot, \cdot)) \). If \( R \) is a ring and \( I \) multiplicative, then \( r \) is a ring homomorphism.

Proof. Let \( \Sigma \) be the (finite set) of cells in an equivariant cell complexes \((X, G)\) (\( \Sigma \) is a \( G \)-set). The additivity property of \( I \) imply that: \( I(X, G) = \sum_{[\sigma] \in \Sigma/G} I(G\sigma, G) \) where \( \sigma = \sigma_k \) is an open cell (of certain dimension \( k \)) in \( X \): a representative of the orbit \([\sigma] \), \( G\sigma \) is the union \( \bigcup_{g \in G} g\sigma \) of the \( G \)-shifts of \( \sigma \).

Let \( G_{\sigma_k} \) be the isotropy group of the cell \( \sigma_k \). (Let us recall that \( G_\sigma \) acts trivially on \( \sigma \).) One has \( G_{\sigma_k} = (G/G_{\sigma_k}) \times \sigma_k \), where \( G/G_{\sigma_k} \) is a finite \( G \)-set. Just as in the proof of Proposition 1 one has

\[
I(G_{\sigma_k}G, G) = (-1)^k I((G/G_{\sigma_k}) \times \{pt\}, G).
\]

The induction property implies that \( I((G/G_{\sigma_k}) \times \{pt\}, G) = I(G_{\sigma_k}/G_{\sigma_k}) \times \{pt\}, G_{\sigma_k} \). Let us denote \( I(G/G \times \{pt\}, G) \) by \( \tau_G \). One can see that group homomorphism \( r : R \to R \) which sends \( \chi(\cdot, \cdot) \) to \( I(\cdot, \cdot) \) is defined by \( r(T^G) = \tau_G \). The multiplicativity of \( r \) in the case when \( I \) is multiplicative is obvious. \( \square \)

6 \( \lambda \)-ring structures on \( R \) and the correspondig power structures

A way to formulate an analogue of Macdonald type equations for an (additive and multiplicative) invariant with values in a ring \( R \) is through the so called power structure over the ring \( R \): [9]. A power structure over a ring \( R \) is a method to give sense to an expression of the form \((1 + a_1 t + a_2 t^2 + \ldots)^m \) with \( a_i, m \in R \) as a power series form \( 1 + tR[\![t]\!] \) so that all properties of the usual exponential function hold. The notion of a power structure over a ring \( R \) is related with the notion of a \( \lambda \)-ring (some times called a pre-\( \lambda \)-ring) structure on \( R \): [14].

We will describe two \( \lambda \)-ring structures on the ring \( R \) appropriate for the formulation of Macdonald type equations for the symmetric products and for the configuration spaces. As it was explained, \( R \) is the ring of
polynomials in the variables $T_G$ corresponding to the isomorphism classes $G$ of indecomposable finite groups. The standard $\lambda$-ring structure on the polynomial ring $\mathbb{Z}[x_1, x_2, x_3, \ldots]$ (see, e. g., [14]) is defined in the following way: for

$$p(\overline{x}) = \sum \overline{x}^p \in \mathbb{Z}[x_1, x_2, x_3, \ldots],$$

one has

$$\lambda_p(\overline{x})(t) = \prod \left(1 - \overline{x}^p t\right)^{-p}.$$  \hspace{1cm} (4)

Equation (4) follows directly from the equation for the $\lambda$-series corresponding to a monomial:

$$\lambda_{x^k}(t) = \left(1 - x^k t\right)^{-1}.$$

Natural $\lambda$-rings structures on $\mathcal{R}$ are different ones. To define a $\lambda$-ring structure on $\mathcal{R}$, one can define the $\lambda$-series, say, $\nu_{T_G}(t)$ for a monomial $T_G$ from $\mathcal{R}$. Namely, if the series $\nu_{T_G}(t)$ is defined for all $\{G\} \in \mathcal{G}$ (so that $\nu_{T_G}(t) = 1 + T_G t + \ldots$), then one defines the $\lambda$-series for an element $A = \sum_{\{G\} \in \mathcal{G}} a_G T^G \in \mathcal{R}$ ($a_G \in \mathbb{Z}$) by

$$\nu_A(t) = \prod_{\{G\} \in \mathcal{G}} (\nu_{T_G}(t))^{a_G}.$$

Let us first describe the $\lambda$-rings structure on $\mathcal{R}$ corresponding to the symmetric products of spaces. We will call it the *power product $\lambda$-structure*. This structure will be defined defined by a $\lambda$-series $\zeta_\bullet(t)$. For a finite group $G$, let $G_n = G \wr S_n = G^n \rtimes S_n$ be the corresponding wreath product. Let us define $\zeta_{T_G}(t)$ for the monomial $T^G$ by the equation

$$\zeta_{T_G}(t) = 1 + \sum_{n=1}^{\infty} T^{G_n} t^n.$$  \hspace{1cm} (5)

In particular,

$$\zeta_1(t) = 1 + \sum_{n=1}^{\infty} T^{S_n} t^n.$$

**Remark.** Pay attention that the coefficients of the $\lambda$-series for a monomial are monomials as well.
Let us (partially) describe the series (5) in terms of the variables $T_G$ for the polynomial ring $R$ ($G$ runs through isomorphism classes of indecomposable finite groups). For such a description the variables corresponding to the Abelian groups play a special role. Let $A_{p,k} \cong \mathbb{Z}_{p^k}$ ($p$ is prime, $k \geq 1$) be the indecomposable finite Abelian groups. For a group $G = \prod_{p,k} (A_{p,k})^{l_{p,k}} \prod G(i)^{k_i}$ with non-Abelian indecomposable finite groups $G(i)$, for $n > 1$, one has

$$
\left( \prod_{p,k} A_{p,k}^{l_{p,k}} \prod G(i)^{k_i} \right)_n \cong \left( \prod_{p,k: p \nmid n} A_{p,k}^{l_{p,k}} \right) \times \hat{G}(n),
$$

where $\hat{G}(n)$ is a indecomposable non-Abelian group (depending on the group $G$ of course) (see [15] and also [6] for more precise statements) and therefore

\begin{equation}
\zeta_{\prod_{p,k} T_{A_{p,k}}^{l_{p,k}} \prod G(i)^{k_i}}(t) = 1 + \left( \prod_{p,k} T_{A_{p,k}}^{l_{p,k}} \prod T_{G(i)}^{k_i} \right) t + \sum_{n=2}^{\infty} \left( T_{\hat{G}(n)} \prod_{p,k: p \nmid n} T_{A_{p,k}}^{l_{p,k}} \right) t^n.
\end{equation}

The described $\lambda$-ring structure on $R$ defines (in the usual way: see [9], [10]) a power structure over $R$. We will call it the symmetric product power structure. Let us recall that according to the construction of the power structure one has

$$
(\zeta_1(t))^{T_G} = \zeta_{T_G}(t).
$$

The other $\lambda$-ring structure on $R$ corresponds to the configuration space of spaces. We will call it the configuration space $\lambda$-ring structure. This structure will be defined by a $\lambda$-series $\lambda(t)$. As above it is sufficient to define this series for monomials. Let

$$
\lambda_{T_G}(t) = 1 + T_G t.
$$

In particular, $\lambda_1(t) = 1 + t$.

This $\lambda$-ring structure on $R$ defines the corresponding configuration space power structure over $R$. The described power structures (the symmetric product and the configuration space ones) over $R$ are different: see computations in [12, page 17].

From [12] and the interpretation of $R$ given above it follows that the configuration space power structure over $R$ is effective in the following sense. Let $R_+$ be the subsemiring of $R$ consisting of polynomials in $T_G$ with non-negative coefficients. The effectiveness of the power structure means that if
$a_i$ and $m$ are from $\mathcal{R}_+$, then all the coefficients of the series $(1 + a_1 t + a_2 t^2 + \ldots)^m$ belong to $\mathcal{R}_+$ as well.

Remark. The fact that this power structure is effective is not a direct consequence of the equation (7) for the $\lambda$-series. The effectiveness of the configuration space power structure is a consequence of an explicit equation for it: see [12, Equation 10]. The symmetric product power structure over $\mathcal{R}$ is not effective: see again [12, page 17].

7 Macdonald type equations for the universal Euler characteristics for symmetric products

Let $Q$ be a (tame) $V$-manifold. The $n$-th symmetric power $S^nQ$ of $Q$ is the $V$-manifold defined in the following way. The underline space of $S^nQ$ is the $n$-th symmetric power $S^nX_Q$ of the underline space $X_Q$ of the $V$-manifold $Q$. Let

$$ \underline{x} = (x_1, \ldots, x_1, \ldots, x_s, \ldots, x_s) $$

where $x_i, i = 1, \ldots, s$, is a point of $X_Q$ with the multiplicity $k_i$ in $\underline{x}$, $\sum_{i=1}^s k_i = n$, $x_i \neq x_j$ for $i \neq j$, be a point of $S^nX_Q$ and let $(U_i, \tilde{U}_i, G(i), \varphi_i)$ be local uniformizing systems for neighbourhoods $U_i$ of the points $x_i$ such that $U_i \cap U_j = \emptyset$ for $i \neq j$. Then the orbifold structure on $S^nQ$ in a neighbourhood of $\underline{x}$ is defined by the local uniformizing system $(\underline{S}^{k_1} U_1 \times \ldots \times \underline{S}^{k_s} U_s, \tilde{U}^{k_1}_1 \times \ldots \times \tilde{U}^{k_s}_s, (G(1))_{k_1} \times \ldots \times (G(s))_{k_s}, \varphi)$, where $(G(i))_{k_i}$ is the wreath product $G(i) \wr S_{k_i}$ acting on the Cartesian power $U_i^{k_i}$ in the usual way, $\varphi = (\varphi_1 \times \ldots \times \varphi_1 \times \ldots \times \varphi_s \times \ldots \times \varphi_s)$.

Theorem 3 For a $V$-manifold $Q$ one has

$$ 1 + \sum_{n=1}^\infty \chi^{un}(S^nQ) t^n = \zeta_{\chi^{un}(Q)}(t) = (\zeta_1(t))^{\chi^{un}(Q)}, \quad (8) $$

where the right hand side is written in terms of the symmetric product power structure over $\mathcal{R}$.

Let us recall that, if $\chi^{un}(Q) = \sum_{\{G\} \in \mathcal{G}} a_G T^G$, then

$$ \zeta_{\chi^{un}(Q)}(t) = \prod_{\{G\} \in \mathcal{G}} (1 + T^G t + T^{G_2} t^2 + T^{G_3} t^3 + \ldots)^{a_G}. $$
Proof. Let us denote the left hand side of Equation (8) by $\xi_Q(t)$. If $Q'$ is a closed $V$-submanifold of $Q$, one has $\xi_Q(t) = \xi_{Q'}(t)\xi_{Q\setminus Q'}(t)$. (This follows from the fact that $S^n Q$ is the disjoint union of $S^k Q' \times S^{n-k}(Q \setminus Q')$ for $0 \leq k \leq n$.) The representation of $Q$ as the disjoint union of the sub-$V$-manifolds $Q_{G}(G)$ permits to prove the statement for $Q = MT^G$ for a $C^\infty$-manifold $M$ (with the action of the trivial group). A representation of $M$ as a cell complex permits to prove the statement for $Q = \sigma^k T^G$, where $\sigma^k$ is an open cell of dimension $k$. The fact that a $k$-dimensional cell can be represented as the union of two $k$-dimensional cells and one $(k-1)$-dimensional cell implies that

$$\xi_{\sigma^k T^G}(t) = (\xi_{\sigma^k T^G}(t))^{(-1)^k}.$$ 

Therefore it is sufficient to show (8) for $Q = \sigma^0 T^G$. In this case we have

$$\xi_{\sigma^0 T^G}(t) = 1 + T^G t + T^G t^2 + T^G t^3 + \ldots = \zeta_{T^G}(t) = (\zeta_1(t))^{T^G} = (\zeta_1(t))^{\chi_{\text{un}}(\sigma^0 T^G)}.$$

□

One has a Macdonald type equation for equivariant cell complexes (and therefore for representatives $(X, G)$ of elements of the Grothendieck ring $K^G_C(\text{Var}_C)$). For a cell complex $(X, G)$, let $(X^n, G_n)$ be the Cartesian power of the complex $X$ with the standard action of the wreath product $G_n$.

**Theorem 4** For an equivariant cell complex $(X, G)$, one has

$$1 + \sum_{n=1}^{\infty} \chi_{\text{un}}(X^n, G_n)t^n = \xi_{\chi_{\text{un}}(X,G)}(t) = (\zeta_1(t))^{\chi_{\text{un}}(X,G)}.$$

(the right hand side is in terms of the symmetric product power structure).

The proof is essentially the same as the one of Theorem 8 with the only difference that the general case is reduced not to $\sigma^k T^G$, but to $\sigma^k \times (G/G_{\sigma^k})$.

8 Macdonald type equations for the universal Euler characteristics for configuration spaces

For a $V$-manifold $Q$, its $n$-th configuration space $M_n Q$ is the $V$-manifold defined in the following way. Its underline space is $M_n X_Q = (X^n_Q \setminus \Delta)/S_n \subset$
$S^nX_Q$; the $V$-manifold structure on it comes from the one in $S^nX_Q$. (Pay attention that one has to define local uniformizing systems only for points $x = (x_1, \ldots, x_n)$ with $x_i \neq x_j$ if $i \neq j$.)

**Theorem 5** For a $V$-manifold $Q$, one has

$$1 + \sum_{n=1}^{\infty} \chi^{un}(M_n Q)t^n = \lambda_{\chi^{un}(Q)}(t) = (1 + t)^{\chi^{un}(Q)}.$$  

(9)

where the right hand side is written in terms of the configuration space power structure over $\mathcal{R}$.

Let us recall that $\lambda_1(t) = 1 + t$, if $\chi^{un}(Q) = \sum_{(G) \in \mathcal{G}} a_G T^G$, then

$$\lambda_{\chi^{un}(Q)}(t) = \prod_{\{G\} \in \mathcal{G}} (1 + T^G t)^{a_G}.$$  

An analogue of this equation for equivariant cell complex is given in the following statement. For equivariant cell complex $(X,G)$ and for $n \geq 1$, let $\Delta_G \subset X^n$ be the big $G$-diagonal in $X^n$ consisting of (ordered) $n$-tuples $(x_1, \ldots, x_n) \in X^n$ with at least two of the components $x_i$ from the same $G$-orbit.

**Theorem 6** For an equivariant cell complex $(X,G)$, one has

$$1 + \sum_{n=1}^{\infty} \chi^{un}(X^n \setminus \Delta_G, G_n)t^n = \lambda_{\chi^{un}(X,G)}(t) = (1 + t)^{\chi^{un}(X,G)}.$$  

(the right hand side is in the terms of the configuration space power structure).

Proofs of Theorems 5 and 6 are minor modifications of those of Theorems 3 and 4.
