Abstract
A brief review of the experimental situation concerning the electrically-charged charmoniumlike meson candidates, $Z^-$, is presented.

Introduction
The Belle Collaboration reported peaks in the $\psi'/\pi^-$ invariant mass distributions $^1$ and $\chi_{c1}\pi^-$ invariant mass distributions $^2$ in $B \to \psi'/\pi^-K$ $^3$ and $B \to \chi_{c1}\pi^-K$ $^4$, respectively. These peaks have yet been confirmed by other experiments. An analysis by the BABAR Collaboration of $B \to \psi/\pi^-K$ neither confirms nor contradicts the Belle claim for the $Z(4430)^- \to \psi'/\pi^-$ $^5$. In the BABAR analysis, $B \to J/\psi\pi^-K$ decays were also studied, and no evidence for $Z(4430)^- \to J/\psi\pi^-$ was found.

In this paper, we review and compare Belle and BABAR results on searches for charged charmonium-like states. An abbreviated version of this review is contained in Ref. $^6$.

The Belle observation
Belle’s original $Z(4430)^-$ signal $^3$ is the sharp peak in the $\psi'/\pi^-$ invariant mass distribution from $B \to \psi'/\pi^-K$ decays shown in Fig. $^1$ The Belle analysis is based on a data sample that is equivalent to an integrated luminosity of 605 fb$^{-1}$. Figure $^2$ shows the Dalitz plot for $B \to \psi'/\pi^-K$ candidates, where vertical bands for $K^+(892) \to K\pi^-$ and $K^0_S(1430) \to K\pi^-$ are evident and the $Z(4430)^-$ shows up as a horizontal band of events between $M_{\psi'/\pi^-}^2 = 19$ and 20 GeV$^2$/c$^4$. (In the $\psi'/\pi^-$ invariant mass distribution of Fig. $^1$ the the $K^*$ bands are suppressed by cuts on the $K\pi^-$ masses $^2$).

A binned maximum-likelihood fit to the $\psi'/\pi^-$ mass distribution using a Breit Wigner (BW) resonance function for the signal and a polynomial background gives a mass of $M = 4433 \pm 4 \pm 2$ MeV/c$^2$ and total width of $\Gamma = 45^{+18}_{-13}^{+30}_{-13}$ MeV, with estimated statistical significance of more than 6$\sigma$. Consistent signals are seen in various subsets of the data: i.e. for both the $\psi' \to \ell^+\ell^-$ ($\ell = e$, or $\mu$) and $\psi' \to J/\psi\pi^+\pi^-$ ($J/\psi \to \ell^+\ell^-$) subsamples $^3$.

A reflection from $K\pi$ dynamics?
Identifying resonant structures in the $\psi'/\pi^-$ channel in three-body $B \to \psi'/\pi^-K$ decays has to be done with care because of the possibility that dynamics in the $K\pi^-$ channel can cause mass structures in the $\psi'/\pi^-$ invariant mass distribution that have no relation to $\psi'/\pi^-$ dynamics. Energy-momentum conservation imposes a tight correlation between the decay angle $(\theta_{\pi^-})$ in the $K\pi^-$ system $^7$ and the $\psi'/\pi^-$ invariant mass, and this results in $M_{\psi'/\pi^-}^2$ being very nearly proportional to $\cos \theta_{\pi^-}$. Consequently, interference between different partial waves in the $K\pi^-$ system can produce peaks in $M_{\psi'/\pi^-}$ that are purely “reflections” of structures in $\cos \theta_{\pi^-}$ and have nothing to do with $\psi'/\pi^-$ dynamics. However, in the kinematically allowed $K\pi^-$ mass range for $B \to \psi'/\pi^-K$ decay, only $S$-, $P$- and $D$-waves are significant, and this limited set of partial waves can only produce fake $\psi'/\pi^-$ mass peaks at a discrete set of mass values.

In the case of the $Z(4430)^-$, the $\psi'/\pi^-$ peak mass

The BaBar search for the $Z(4430)^-$

BaBar searched [5] for the $Z(4430)^-$ in the decay modes $B \to ψπ−K$, where $ψ = J/ψ$ or $ψ'$ and $K = K^+$ or $K^0$. The search was performed using the full BaBar data set equivalent to integrated luminosity of 413 fb$^{-1}$ (455×10$^6$ BB candidates) collected at a center-of-mass energy of 10.58 GeV. The BaBar search covered two additional decay modes ($B \to J/ψπ−K$) that were not considered in the Belle study. The $J/ψ$ modes contain about six times (see Table II in Ref. [5]) more data than those with the $ψ'$ and provide a powerful, high statistics tool for understanding the background. The Dalitz plots for the four decay modes are shown in Fig. [4]. The $Kπ^−$ mass distribution shows a clear $K^+(892)$ signal in all decay modes, and a visible $K_2^+(1430)$ signal in the modes with a $J/ψ$ but less significant in the modes with $ψ'$. Since the $Kπ^−$ system dominates the Dalitz plot, the BaBar Collaboration studied the $Kπ^−$ mass distribution and the angular dependence. Similar contributions from the different wave intensities are obtained in the modes with $K_2^0$ and $K^+$ (see Table III in Ref. [5]) and, therefore, the modes with $K_2^0$ and $K^+$ are combined. The $Kπ^−$ mass distributions are fitted...
with the $S$, $P$, and $D$-wave intensities as shown in Fig. 5. Good fits to the data are obtained. The study of the angular dependence shows a clear asymmetry in $\cos \theta_K$, where $\theta_K$ is the angle between the Kaon and $\psi$ meson in the $K\pi^-$ rest frame (see Figs. 12 and 13 in Ref. 5).

The $\text{BaBar}$ mass resolution at the $Z(4430)^-$ mass is $7 \pm 1$ MeV/$c^2$ for the modes with $J/\psi'$ (or $\psi'$) (see Fig. 6 in Ref. 5). Each event is efficiency corrected, and the conclusions are based on distributions obtained after background subtraction. The average efficiency varies slightly as a function of the $K\pi^-$ mass but can differ significantly between the different $\psi$ decay modes (see Fig. 7 in Ref. 5), however there are significant variations in efficiency with $\cos \theta_K$ for certain regions of $K\pi^-$ mass (see Fig. 36 in Ref. 5).

The comparison between the $\psi\pi^-$ mass distribution and the relevant $K\pi^-$ reflection was performed (see section 9 in Ref. 5). This comparison is essential to investigate the need for a $Z(4430)^-$ signal above the $K\pi^-$ reflection. Following the five $K\pi^-$ regions (see section 10.D in Ref. 5) defined in the Belle analysis 3, the projection is implemented in each $K\pi^-$ interval as shown in Fig. 6. In each figure, a comparison (not a fit) between the data and the $K\pi^-$ reflection is shown. Note that only one normalization factor for the $K\pi^-$ regions is used for each $\psi$ mode. The $K\pi^-$ reflections onto the $\psi\pi^-$ mass distributions describe well the data, with a small statistical fluctuation at $m_{K\pi^-} < 0.795$ GeV/$c^2$. The
the $\psi\pi^-$ mass distribution and the overall $K\pi^-$ projection are shown in Fig. 6. No significant evidence for $Z(4430)^-$ has been obtained. The $K\pi^-$ projection onto the $\psi\pi^-$ mass distribution is used as a nonpeaking background. With such a background shape and a BW function for a $Z(4430)^-$ signal, a signal is obtained for the overall $K\pi^-$ region, but with shifted mass value. A similar small signal is obtained in the $K^*(892)$ and $K_2^*(1430)$ combined regions. A $\sim 2\sigma$ peak is obtained when the $K^*(892)$ and $K_2^*(1430)$ regions are vetoed. No (or a negative) signal for $Z(4430)^- \rightarrow J/\psi\pi^-$ was found.

\centering
\includegraphics[width=0.8\textwidth]{figure6}
\caption{From BABAR \cite{9}, the $\psi\pi^-$ mass distributions in different regions of $K\pi^-$ mass for (a-e) $B^{-,0} \rightarrow J/\psi\pi^- K^{0,+}$, and (f-j) $B^{-,0} \rightarrow J/\psi\pi^- K^{0,+}$; the open dots represent the data, and the solid curves and shaded bands are due to the $K\pi^-$ reflections in the different $\psi\pi^-$ mass intervals, using the same overall normalization constant. In (f-j), the dot-dashed curves are obtained using $K\pi^-$ normalized moments for $B^{-,0} \rightarrow J/\psi\pi^- K^{0,+}$, instead of those from $B^{-,0} \rightarrow J/\psi\pi^- K^{0,+}$; the vertical lines indicate $m_{\psi\pi^-} = 4.433$ GeV/c$^2$.}
\end{figure}

Although the Belle Collaboration used a data sample equivalent to 1.46 times that of BABAR's, because of different selection criteria BABAR has more events per fb$^{-1}$. A direct comparison between the two $m_{\psi'\pi^-}$ distributions is shown in Fig. 8. For comparison purposes, the BABAR distribution is not corrected for efficiency, however both Belle and BABAR distributions are background subtracted and shown in Fig. 8(a) and Fig. 8(b), respectively. The BABAR distribution is scaled up by the factor 1.18 in order to normalize to the Belle data between the crosshatched regions of Fig. 8(c). The difference plot is shown in Fig. 8(c) where errors have been combined in quadrature; here $\chi^2/NDF = 54.7/58$, which indicates that the two samples are statistically equivalent.

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{figure7}
\caption{From BABAR \cite{5}, the $\psi\pi^-$ mass distributions for the combined decay modes (a) $B^{-,0} \rightarrow J/\psi\pi^- K^{0,+}$ and (b) $B^{-,0} \rightarrow J/\psi\pi^- K^{0,+}$. The points show the data (integrated over all $K\pi^-$ regions) after efficiency correction and background subtraction. The dashed curves show the $K\pi^-$ reflection for a flat $\cos \theta_K$ distribution, while the solid curves show the result of $\cos \theta_K$ when accounting for the angular dependence (see Sec. 9 in Ref. \cite{5}). The shaded bands represent the effect of statistical uncertainty on the normalized moments. In (b), the dot-dashed curve indicates the effect of weighting with the normalized $J/\psi\pi^- K$ moments. The dashed vertical lines indicate the value of $m_{\psi\pi^-} = 4.433$ GeV/c$^2$. In (c) and (d), we show the residuals (data-solid curve) for (a) and (b), respectively.}
\end{figure}

Belle’s Dalitz analysis of $B \rightarrow \psi'\pi^- K$

After the BABAR Collaboration did not confirm the $Z(4430)^- \rightarrow \psi'\pi^-$ mass peak in their analysis of $B \rightarrow \psi'\pi^- K$ decays \cite{5}, the Belle Collaboration performed a reanalysis \cite{9} of their data that took detailed account of possible reflections from the $K\pi^-$ channel. Specifically, they modeled the $B \rightarrow \psi'\pi^- K$ process as the sum of two-body decays $B \rightarrow \psi'K^+_i$, where $K^+_i$ denotes all of the known $K^* \rightarrow K\pi^-$ resonances that are kinematically accessible, and both with and with-
Figure 8: From Belle [9], (a) The Belle $m_{\psi'\pi^-}$ distribution after background subtraction; (b) the equivalent BaBar $m_{\psi'\pi^-}$ distribution obtained after scaling due to different luminosities. (c) The difference between the $m_{\psi'\pi^-}$ distributions. The crosshatched area represents the exclusion region for the normalization procedure. The vertical-dashed line indicates $m_{\psi'\pi^-} = 4430$ MeV/c$^2$.

out a $B \to Z(4430)^-K$ component. The results of this analysis, confirm the basic conclusions of Belle’s initial publication [5].

Figure 9 shows the $\psi'\pi^-$ mass distribution in different $K\pi^-$ intervals as obtained from the Dalitz-plot analysis by the Belle Collaboration [9]. In the region between the $K^*(892)$ and the $K_2^*(1430)$ ($0.982 < m_{K\pi^+} < 1.332$ GeV/c$^2$, Fig. 9(c)), a $Z(4430)^-$ peak is present. The data points in Fig. 10 show $M_{\psi'\pi^-}^2$ Dalitz plot projections with the prominent $K^*$ bands removed (as in Fig. 1) compared with the results of the fit with no $Z(4430)^-$ resonance, shown as a dashed histogram, and that with a $Z(4430)^-$ resonance, shown as the solid histogram. The fit with the $Z(4430)^-$ is favored over the fit with no $Z(4430)^-$ by $6.4\sigma$. The fitted mass, $M = 4433^{+15}_{-12} +^{19}_{-13}$ MeV/c$^2$, agrees within the systematic errors with the earlier Belle result; the fitted width, $\Gamma = 107^{+86}_{-43} +^{74}_{-56}$ MeV, is larger, but also within the analysis’ systematic er-

rors of the previous result. In the default fit, the $Z(4430)^-$ resonance was assumed to have zero spin. Variations of the fit that included a $J = 1$ assignment for the $Z(4430)^-$ as well as models that included additional, hypothetical $K^* \to K\pi^-$ resonances with floating masses and widths, and radically different parameterizations of the $K\pi^-$ $S$-wave amplitude do not change the conclusions. The product branching fraction from the Dalitz fit: $\mathcal{B}(B^0 \to Z(4430)^-K) \times \mathcal{B}(Z(4430)^- \to \psi'\pi^-) = (3.2^{+1.8}_{-0.9} -^{9.6}_{-1.0}) \times 10^{-5}$ is not in strong contradiction with the BaBar 95% C.L. upper limit of $3.1 \times 10^{-5}$ [5].
Figure 10: From Belle [9], the $M^2_{\psi'\pi^-}$ projection of the Dalitz plot with the $K^*$ bands removed is shown as data points. The histograms show the corresponding projections of the fits with and without a $Z(4430)^-\to \psi'\pi^-$ resonance term.

Belle’s two $Z$ peaks in the $\chi_{c1}\pi^-$ channel

In addition to the $Z(4430)^-$, Belle has presented results of an analysis of $B \to \chi_{c1}\pi^-K$ decays that require two resonant states in the $\chi_{c1}\pi^-$ channel [4]. The $M^2_{K\pi^-}$ vs. $M^2_{\chi_{c1}\pi^-}$ Dalitz plot, shown in Fig. 11, shows vertical bands of events corresponding to $K^*(892)\to K\pi^-$ and $K^*_2(1430)\to K\pi^-$, plus a broad horizontal band near $M^2_{\chi_{c1}\pi^-} \simeq 17.5$ GeV$^2$/c$^4$, indicating a possible resonance in the $\chi_{c1}\pi^-$ channel. In this case, this horizontal band corresponds to $\cos \theta_{\pi^-} \simeq 0$, a location where interference between partial waves in the $K\pi^-$ channel can produce a peak and, thus, a detailed Dalitz analysis is essential.

For $B \to \chi_{c1}\pi^-K$, the kinematically allowed mass range for the $K\pi^-$ system extends beyond the $K^*_2(1780)$ $F$-wave resonance and $S^-, P^-, D^-$ and $E$-wave terms for the $K\pi^-$ system are included in the model. The fit with a single resonance in the $Z^-\to \chi_{c1}\pi^-$ channel is favored over a fit with only $K^*$ resonances and no $Z^-$ by more than 10$\sigma$. Moreover, a fit with two resonances in the $\chi_{c1}\pi^-$ channel is favored over the fit with only one $Z^-$ resonance by 5.7$\sigma$. The fitted masses and widths of these two resonances are: $M_1 = 4051 \pm 14^{+20}_{-21}$ MeV/c$^2$ and $\Gamma_1 = 82^{+21}_{-17} + 47^{+30}_{-22}$ MeV and $M_2 = 4248^{+14}_{-19} + 180^{+35}_{-55}$ MeV/c$^2$ and $\Gamma_2 = 177^{+54}_{-39} + 316^{+66}_{-61}$ MeV. Here also, variations of the fit that use a $J = 1$ assignment for the $Z^-$ states and models that include additional, hypothetical $K^*$ $\to K\pi^-$ resonances with floating masses and widths, and different parameterizations of the $K\pi^-$ $S$-wave amplitude do not change the conclusions.

The product branching fractions for $B \to Z^-\to \chi_{c1}\pi^-K$ have central values similar to that for the $Z(4430)^-$ but with large errors. Figure 12 shows the $M_{\chi_{c1}\pi^-}$ projection of the Dalitz plot with the $K^*$ bands excluded and the results of the fit with no $Z^-\to \chi_{c1}\pi^-$ resonances and with two $Z^-\to \chi_{c1}\pi^-$ resonances.

Summary

If the peaks reported by Belle in the $\psi'\pi^-$ and $\chi_{c1}\pi^-$ channels are in fact meson resonances, they would be “smoking guns” for exotics. It is therefore important that the Belle results are confirmed (or refuted) by other experiments. Both the $\text{BaBar}$ and Belle $\psi'\pi^-$ analyses could benefit from additional
Figure 12: From Belle \cite{4}, the data points show the $M_{\chi c_1\pi^-}$ projection of the Dalitz plot with the $K^*$ bands removed. The histograms show the corresponding projections of the fits with and without the two $Z \to \chi c_1\pi^-$ resonance terms.

...statistics. However, both experiments have completed data taking and the BABAR analysis used their complete dataset while the Belle analysis used about 75\% of their final total data sample. Approximately 3 $\text{ab}^{-1}$ of integrated luminosity would be necessary to bring the $\psi'\pi^-$ sample to the statistical level of BABAR’s current $J/\psi\pi^-$ sample, and this amount of data will not be available until the operation of one of the SuperB factories, which will not happen for at least a few years. In the meantime, it would be valuable if BABAR performed a search for the $Z_1(4050)^-$ and $Z_2(4250)^-$ in the $\chi c_1\pi^-$ channel and Belle reproduced BABAR’s study of the $J/\psi\pi^-$ channel using the existing data sets. The D0 and CDF experiments at the Tevatron have data on hand that could be used to carry out searches for inclusive production of the $Z(4430)^-$ and we hope that results will be available from them in the near future.
