Differences in neurochemical profiles of two gadid species under ocean warming and acidification

Matthias Schmidt 1,2, Heidrun Sigrid Windisch 3, Kai-Uwe Ludwichowski 4, Sean Lando Levin Seegert 1, Hans-Otto Pörtner 1,2, Daniela Storch 1 and Christian Bock 1*

Abstract

Background: Exposure to future ocean acidification scenarios may alter the behaviour of marine teleosts through interference with neuroreceptor functioning. So far, most studies investigated effects of ocean acidification on the behaviour of fish, either isolated or in combination with environmental temperature. However, only few physiological studies on this issue were conducted despite the putative neurophysiological origin of the CO 2-induced behavioural changes. Here, we present the metabolic consequences of long-term exposure to projected ocean acidification (396–548 μatm PCO2 under control and 915–1272 μatm under treatment conditions) and parallel warming in the brain of two related fish species, polar cod (Boreogadus saida, exposed to 0 °C, 3 °C, 6 °C and 8 °C) and Atlantic cod (Gadus morhua, exposed to 3 °C, 8 °C, 12 °C and 16 °C). It has been shown that B. saida is behaviourally vulnerable to future ocean acidification scenarios, while G. morhua demonstrates behavioural resilience.

Results: We found that temperature alters brain osmolyte, amino acid, choline and neurotransmitter concentrations in both species indicating thermal responses particularly in osmoregulation and membrane structure. In B. saida, changes in amino acid and osmolyte metabolism at the highest temperature tested were also affected by CO 2, possibly emphasizing energetic limitations. We did not observe changes in neurotransmitters, energy metabolites, membrane components or osmolytes that might serve as a compensatory mechanism against CO 2 induced behavioural impairments. In contrast to B. saida, such temperature limitation was not detected in G. morhua; however, at 8 °C, CO 2 induced an increase in the levels of metabolites of the glutamate/GABA-glutamine cycle potentially indicating greater GABAergic activity in G. morhua. Further, increased availability of energy-rich substrates was detected under these conditions.

Conclusions: Our results indicate a change of GABAergic metabolism in the nervous system of Gadus morhua close to the optimum of the temperature range. Since a former study showed that juvenile G. morhua might be slightly more behaviourally resilient to CO 2 at this respective temperature, we conclude that the observed change of GABAergic metabolism could be involved in counteracting OA induced behavioural changes. This may serve as a fitness advantage of this respective species compared to B. saida in a future warmer, more acidified polar ocean.

Behavioural consequences of CO2 during concomitant acidification until the end of the twenty-first century. G. morhua and other utilized fish species [14, 15]. Both, B. saida is only minor, compared to that for saida sequences [10]. While direct commercial interest in the seas around Svalbard with uncertain ecological consequences already overlaps with the distribution of B. saida [13] and already overlaps with the distribution of B. saida in the seas around Svalbard with uncertain ecological consequences [10]. While direct commercial interest in B. saida is only minor, compared to that for G. morhua. Its importance lies mainly in its function as forage for several other utilized fish species [14, 15]. Both, B. saida and G. morhua, will experience further warming and acidification until the end of the twenty-first century. Behavioural consequences of CO2 during concomitant warming have so far only been assessed in a few fish species [16–18]. Furthermore, studies of the combined effects of these two factors on brain metabolism have not been conducted at all.

The present study focuses particularly on metabolites and amino acids involved in energy metabolism and regeneration of the neurotransmitter γ-aminobutyric acid (GABA) in order to test whether compensatory mechanisms to a rise of environmental CO2 are visible on neurotransmitter level. In addition, we studied the neurotransmitter serotonin (5-HT) and its catabolite since serotonergic activity is positively correlated with chronic stress in fish [19]. Compounds involved in the metabolism of phospholipids were also analysed since Leo et al. found that CO2 might affect proton leakage in mitochondria of G. morhua and other teleosts [20, 21].

Methods
Specimen collection and maintenance
Juvenile Boreogadus saida were caught on January 17th 2013 in the inner Kongsfjord (78.97 N, 12.51 E) at an approximate depth of 120 m. They were housed in aquaria of the Tromso Aquaculture Research Station, in Kårvik, Norway before being transported to the Alfred Wegener Institute in Bremerhaven, Germany (AWI). Juvenile Gadus morhua were collected between the 26th and 29th of August 2013 during a cruise of the RV Heincke around Hinlopenstretet (79.30 N, 18.57 E), Rijpfjorden (80.15 N, 22.12 E), and Forlandsundet (78.54 N, 11.3 E) and were subsequently transported to the AWI. Additional information on the cruise is provided under http://doi.pangaea.de/10.1594/PANGAEA.824703. Animals were kept in a recirculating seawater system at the AWI at 5 °C and environmental PCO2 until onset of the incubations.

Incubations
Extensive information on the incubation and animals has been provided by Kunz et al. [22]. Incubation periods were 102–114 days for B. saida and 111–132 days for G. morhua. B. saida (length: 14.4 ± 1.1 cm; weight: 18.0 ± 4.9 g) was incubated at 0 °C, 3 °C, 6 °C and 8 °C and G. morhua (length: 18.0 ± 2.0 cm; weight: 39.5 ± 14.9 g) at 3 °C, 8 °C, 12 °C and 16 °C. Temperatures were chosen in order to represent a wide range of the thermal habitat. At each temperature, animals were kept either at ambient control PCO2 (396–548 μatm.) or high PCO2 (915–1272 μatm.), as projected for the year 2100 [12]. The factorial design was comprised of 8 different treatment groups per species. Means and standard deviations of PCO2 for each treatment group are presented in Additional file 1: Table S1. Temperatures were adjusted by a maximum of 2 °C per day beginning at 5 °C. Afterwards, CO2 conditions were adjusted during a single day. The incubation started after the desired temperature and CO2 conditions had been reached. Animals were kept in individual tanks to avoid cannibalism and changes in the neurochemical profile due to dominance hierarchies.

A gas mixing system (HTK, Germany) was used for adjustment of PCO2. Temperature, salinity, dissolved
inorganic carbon (DIC) and pH$_{tot}$ were measured at least once per week. Extensive information on the methodology of carbonate chemistry measurements and raw data are available under https://doi.pangaea.de/10.1594/PANGAEA.866369. A summary of the carbonate chemistry for the whole incubation period has been published by Kunz et al. [22].

**Tissue sampling and preparation**

After incubation, animals were exposed to surgical anaesthesia at 200 mg/l MS-222 in a water bath containing seawater from aquaria of the respective treatment group. When the fish did not respond anymore to external stimuli, they were taken out of the water bath and sacrificed though cervical dislocation. Brains were removed, transferred to centrifuge tubes, rapidly frozen in liquid nitrogen and subsequently stored at −80 °C. In order to enable NMR and HPLC analysis on the same tissue samples, each brain was powdered with mortar and pestle under liquid nitrogen. The grind was well mixed and aliquots of ~50 mg were taken for NMR and HPLC measurements. The remaining brains were utilized in experiments not covered by the scope of this paper.

**Untargeted metabolic profiling (using $^1$H–NMR-spectroscopy)**

Extraction of brain tissue was conducted after Belle et al. [23]. Briefly, one aliquot of powdered brain tissue was transferred into a cooled glass centrifuge tube on ice. 3 ml ice-cold Dichloromethane/Methanol (2:1 v/v) were
added quickly and the suspension mixed. The tube was sonicated for ten minutes at 4 °C in a Branson sonifier with 50% duty cycle. Subsequently, 1 ml 0.88% KCl (w/w) was added, the suspension was mixed again and centrifuged for ten minutes at 805 g. The upper methanol phase was transferred to another centrifuge tube and the solution dried overnight in a vacuum concentrator (RVC 2–18 HCl, Christ GmbH Osterode, Germany). The remaining pellet was stored for two to three days at 4 °C in a fridge before being re-suspended in D$_2$O (Deuterium oxide) containing 0.05% TSP (Trimethylsilylpropionate) as internal standard. Two to four fold the weight of the original grind of D$_2$O was added in a volume equivalent (depending on the amount of initial brain tissue) to suspend the pellet. Untargeted metabolic profiling based on $^1$H–NMR spectroscopy was performed on a wide-bore 400 MHz NMR spectrometer (9.4 T WB with Avance III HD electronics, Bruker Biospin, Germany) using a triple tuned $^1$H–$^{13}$C–$^{31}$P-HRMAS NMR probe. A sample volume of ~ 50 μl was filled in a standard zirconium rotor for high-resolution magic angle spinning (HRMAS) NMR spectroscopy. All NMR spectra were conducted at a spinning rate of 3000 Hz and a sample temperature of 10 °C. Four different $^1$H–NMR measurements were collected for all samples, consisting of a standard one pulse 1D $^1$H NMR spectroscopy with f1 pre-saturation, a 1D Carr-Purcell-Meiboom-Gill (CPMG) pulse train including f1 pre-saturation (Bruker protocol cpmgr1d), a NOESY sequence and a pseudo 2D $^1$H–$^1$H J-resolved (JRES) NMR spectroscopy protocol for metabolite identification. All metabolite profiles were analysed from the CPMG NMR protocol with the following acquisition parameters: pulse length 8.4 μs for 90°, time domain 70,656, sweep width of 8802 Hz (22 ppm), acquisition time 4.01 s, relaxation delay 4 s, four dummy scans and 64–256 number of scans depending on the signal-to-noise ratio.

Samples were analysed in randomized order to avoid systematic errors. All spectra were analysed using Chenomx NMR suite 8.1 (Chenomx Inc., Canada). Data were automatically zero filled to at least 128 k and processed with an exponential multiplication of 0.3 Hz. After phase and baseline correction line-shape distortions were eliminated through shim correction. Metabolites were identified using the Chenomx data base and an online spectral data base for organic compounds (http://sdbs.db.aist.go.jp, SDBS, National Institute of Advanced Industrial Science and Technology (AIST)). NMR peak integrals were fitted manually to the specific metabolites for quantification. In total, 24 compounds were identified: Acetate, creatine, lactate, phosphocreatine and succinate are mainly part of cellular energy metabolism; alanine, GABA, glutamine and glutamate are involved in metabolism of GABA either as part of the GABA-glutamine cycle or the lactate-alanine shuttle (lactate is also listed among the metabolites involved in energy metabolism). Compounds involved in the metabolism of phosphatidylcholine are choline, glycerophosphocholine, phosphocholine and putrescine. Acetyl-histidine, myo-inositol (MI), N-acetylaspartate (NAA), taurine and trimethylamine-N-oxide (TMAO) serve as osmolytes in the central nervous system. In addition to its function as osmolyte, NAA is further involved in energy metabolism (Fig. 1). Glycine was quantified as it serves together with GABA as important inhibitory neurotransmitter throughout the central nervous system [24]. Peaks of ascorbate, aspartate, threonine and valine were mostly visible, however, either close to detection limit, or strongly overlapping with other, more prominent, compounds. As a reliable quantification of these substances was not possible, they were excluded from subsequent analysis. Methanol is a trace compound from the extraction process and was therefore also not further analysed. The spectrum of acetyl-histidine was not available in the Chenomx data base and was created manually in the Chenomx compound builder prior to analysis. We detected strong differences in metabolite concentrations between samples, which are likely caused by different extraction efficiencies. To compensate for this bias, we calculated for each spectrum total creatine (tCr) - the sum of creatine and phosphocreatine- as internal reference. Afterwards, the concentration of each metabolite relative to the concentration of tCr was calculated and these ratios were used for statistical analysis. For Boreogadus saida, the brains of 38 individuals were analysed, for Gadus morhua, the brains of 40 individuals. The exact group sizes are document in Additional file 1: Table S1.

HPLC-analysis
Deionized water was utilized for preparation of all buffers. All chemicals used were either of HPLC-grade of the highest purity available. HPLC-analysis of brain tissue was conducted with a modified method of Yoshitake et al. [25] through derivatization with benzylamine (BA) and diphenylethylenediamine (DPE) followed by subsequent fluorescence detection. BA was dissolved 0.3 M in an aqueous solution with 90% methanol (v/v). A 0.3 M CAPS buffer was prepared in aqueous 90% methanol (v/v) and subsequently adjusted to a pH of 11 with 10 M NaOH. Potassium hexacyanoferrate (III) was prepared in an aqueous 50% methanol (v/v). A 0.2 M DPE solution was prepared in methanol and subsequently diluted by 50% with 0.2 M aqueous HCl. Glycine was prepared 0.3 M in H$_2$O. Two derivatisation reagents were made: First, derivatisation reagent “A” containing the above prepared BA, CAPS, potassium hexacyanoferrate solutions
and methanol in a stoichiometry of 2:6:3:24 (v/v/v/v). Second, derivatisation reagent “B” containing the prepared DPE and glycine solutions in a stoichiometry of 2:1 (v/v).

Powdered brain tissue in a centrifuge cup was extracted by adding 0.1 N ice-cold aqueous perchloric acid with 10⁻⁷ M ascorbic acid at a volume of ten-fold the weight of the grind. The cup was mixed and sonicated for two minutes at 4 °C in a Branson sonifier with 50% duty cycle. The cup was subsequently centrifuged at 5200 g for 30 min at 4 °C and the supernatant transferred to a different centrifuge cup. The supernatant was brought to a pH of ~4.5 through addition of 0.5 M ice-cold KOH and subsequently centrifuged again for 30 min at 4 °C.

Reversed phase solid phase extraction was conducted with Oasis HLB cartridges (Waters Corporation, Milford, USA), containing 30 mg sorbent per cartridge with 1 ml methanol as solvent for the eluate. The eluate was dried overnight in a centrifuge cup in a vacuum concentrator (RVC 2–18 HCl, Christ GmbH Osterode, Germany). On the next day, the pellet was dissolved in 200 μl H₂O. 200 μl of derivatisation reagent “A” was added and allowed to react for two minutes at room temperature. Subsequently, 200 μl of derivatisation reagent “B” was added and the mixture incubated for 20 min at 50 °C after which it was rapidly cooled on ice. The solution was filtered through a 20 μm filter and transferred into an amber-coloured glass vial. Measurements were conducted overnight in a HPLC system at room temperature with a LaChrom Elite® (Hitachi High Technologies America, USA) on a reversed phase Kinetex C18 column (Phenomenex, length: 150 mm; diameter: 4.6 mm; particle size: 2.6 μm). We achieved separation through a non-isocratic elution with fractions of two media: first, a 15 mM sodium acetate, 1 mM octanesulfonic acid buffer (pH 4.5) that was diluted with acetonitrile (1:2 (v/v)) and, second, pure acetonitrile. The used proportions are available in Additional file 2: Table S2. Measurement time was 90 min per sample at a flow rate of 0.6 ml/min. Components were identified through their specific retention times using a fluorescence detector with an excitation wavelength of 345 nm and emission wavelength of 480 nm. Using their specific retention times, components were identified through their specific retention times using a fluorescence detector with an excitation wavelength of 345 nm and emission wavelength of 480 nm.

Results
Table 1 depicts a synopsis of temperature-, CO₂- and interactive effects on the analysed components. Boxplots of those components influenced either by CO₂ or interactively by CO₂ in combination with temperature are shown in Fig. 3 (Boreogadus saida) and Fig. 4 (Gadus morhua). Complementary boxplots of all compounds, including those affected by temperature only, are available in the Additional file 4: Figure S1 and Additional file 5: Figure S2 for NMR-data, Additional file 6: Figure S3 for HPLC-data.

Compound classes are assigned to match the grouping of each compound as used throughout the discussion of the manuscript.

* = p < 0.05, ** = p < 0.01, *** = p < 0.001. † and ‡ indicate either an increase or a decrease of the respective compound with rising temperature or rising CO2. ↓ indicates apparent uneven effects. Interactive effects are per definition uneven and were therefore not characterized. A plot for each component is available in the (Additional file 4: Figure S1 and Additional file 5: Figure S2 (NMR) and Additional file 6: Figure S3 (HPLC)).

**Boreogadus saida** - NMR

Figure 2 presents a typical 1H-NMR cpmg spectrum from a methanol/dichloromethane extract of *Boreogadus saida* brain tissue. Temperature strongly affected most compounds tested in this species. Most evident changes were observable among osmolytes, in particular MI, the concentration of which was around 80% lower at 8 °C than at 0 °C (p < 0.001, F3,30 = 267.3, Fig. 3a). A similar reduction with increasing temperature was observed for TMAO (p < 0.001, F3,30 = 56.44). In a striking contrast, NAA increased with rising temperature by about 30% between 0 °C and 8 °C (p < 0.001, F3,30 = 39.06). Taurine exhibited the highest concentration at 6 °C, decreasing above and below this temperature (p < 0.01, F3,30 = 5.299). Acetyl-histidine was not influenced by temperature (p > 0.05). All tested substances directly involved in GABA metabolism showed a reduced concentration with increased temperature. This effect was most prevalent for glutamate and GABA (p < 0.001, F3,30 = 42.87 and p < 0.001, F3,30 = 52.37, Fig. 3b and c respectively). The effect of temperature on alanine and glutamine was weaker and mainly caused by a decrease from 6 °C to 8 °C (p < 0.001, F3,30 = 14.15 and p < 0.05, F3,30 = 4.417).

Among compounds representing energy metabolism only lactate was reduced through temperature increase (p < 0.01, F3,30 = 4.547), an effect which was particularly prevalent between 6 °C and 8 °C. Acetate and succinate were not affected by temperature (p > 0.05). Most membrane components tested were affected by temperature with the exception of choline (p > 0.05). Putrescine and phosphocholine concentrations followed a bell-shaped curve with highest concentrations at 3 °C and 6 °C (p < 0.001, F3,30 = 7.892 and p < 0.01, F3,30 = 6.693). Glycero phosphocholine concentrations decreased significantly with increasing temperature (p < 0.001, F3,30 = 87.42). Glycine was significantly reduced during warming (p < 0.05, F3,30 = 3.637) with a change particularly strong between 6 °C and 8 °C. Simultaneously, glycine displayed a reduction of variance with increasing temperature which was detected with Bartlett test for variance homogeneity.

CO2-effects were visible for the osmolyte MI and for GABA (p < 0.001, F1,30 = 23.58 and p < 0.05, F1,30 = 4.478). CO2 caused an increase in the concentrations of these compounds, mainly at 8 °C. However, CO2-effects were much lower than the observed
temperature-related changes and post-hoc-tests therefore negative.

Interactive effects of temperature and CO$_2$ were detected in the changes of glutamate content which is involved in GABA metabolism ($p < 0.001$, $F_{3,30} = 7.217$).

Non-metric multidimensional scaling supports the conclusion that the variance in metabolite levels is largely explainable through temperature effects ($p < 0.001$, $R^2 \approx 0.93$, 10$^3$ permutations, Additional file 7: Figure S4) with only a small contribution by CO$_2$ ($p \approx 0.6$, $R^2 \approx 0.03$, 10$^3$ permutations).

**Boreogadus saida** - HPLC

Warming caused a significant change in serotonin metabolism with an increase of the HIAA/5-HT ratio ($p < 0.05$, $F_{3,31} = 3.525$, Additional file 6: Figure S3A). Neither CO$_2$, nor interactive effects with temperature were detected.

**Fig. 2** Exemplary $^1$H–NMR spectrum of a brain methanol/dichloromethane extract of *Boreogadus saida*. The x-axis represents the chemical shift of the respective compounds in parts per million (ppm). Ace = Acetate; AcHis = Acetyl-histidine; Ala = Alanine; Asc = Ascorbate; Asp = Aspartate; Cr + PCr = Creatine and Phosphocreatine; GABA = Gamma-aminobutyric acid; Gln = Glutamine; Glu = Glutamate; Gly = Glycine; Lac = Lactate; Lip = Lipids including choline, glycerophosphocholine and phosphocholine; MI = Myo-inositol; NAA = N-acetylaspartate; Put = Putrescine; Suc = Succinate; Tau = Taurine; Thr = Threonine; TMAO = Trimethylamine-N-Oxide

**Fig. 3** Boxplots depicting concentrations of metabolites affected by CO$_2$ (direct or interactive effects, relative to total creatine (tCr), relative units [r.u.]) in the brain of *Boreogadus saida* at different temperatures and CO$_2$ partial pressures. White shading indicates control, grey shading high CO$_2$ partial pressure. Each box contains median, first and third quartile as well as respective standard deviation. Different letters (a, b, c, d, e) indicate significant differences between treatment groups detected by Tukey HSD post hoc analysis ($p < 0.05$).
**Gadus morhua** – NMR

As in *B. saida*, most compounds tested were affected by environmental temperature. The strongest changes were again observed among osmolytes. In particular, MI fell by >90% during warming from 3 °C to 16 °C (*p* < 0.001, *F*$_{3,32}$ = 986.5). The greatest reduction by ~75% occurred between 3 °C and 8 °C. A similar reduction by ~90% between 3 °C and 16 °C was observed for TMAO with the greatest drop again between 3 °C and 8 °C (*p* < 0.001, *F*$_{3,32}$ = 60.87). In contrast to MI and TMAO, NAA increased significantly by about 50% between 3 °C and 16 °C (*p* < 0.001, *F*$_{3,32}$ = 70.95). Taurine concentrations were highest at 3 °C and 8 °C and dropped beyond 8 °C (*p* < 0.001, *F*$_{3,32}$ = 12.97). Acetyl-histidine was not affected by temperature (*p* > 0.05). Similar to *B. saida*, concentrations of most compounds involved in GABA metabolism strongly decreased with increasing temperature. This temperature effect was again strongest for glutamate (*p* < 0.001, *F*$_{3,32}$ = 87.38), followed in magnitude by GABA (*p* < 0.001, *F*$_{3,32}$ = 32.16, Fig. 4c). The temperature effect on glutamine was less clear. Means of glutamine at 12 °C and 16 °C were higher than at 3 °C and 8 °C, however, with the exception of the 3 °C control-CO$_2$ group. Differences in glutamine levels between groups were rather small and post hoc tests negative (*p* > 0.05). The overall temperature effect though, was still slightly significant (*p* < 0.05, *F*$_{3,32}$ = 4.370). Acetate, lactate and succinate levels were not altered by temperature (*p* > 0.05). As in *B. saida*, most components involved in membrane metabolism were affected by temperature, except for choline (*p* > 0.05, Fig. 4b). Putrescine, phosphocholine and glycerophosphocholine level fell during warming (*p* < 0.001, *F*$_{3,32}$ = 11.28, *p* < 0.001, *F*$_{3,32}$ = 78.03 and *p* < 0.001, *F*$_{3,32}$ = 121.0). As in *B. saida*, glycine concentrations decreased with rising temperatures (*p* < 0.001, *F*$_{3,32}$ = 40.17).

A significant CO$_2$ effect was observed for lactate with an increase under high CO$_2$ (*p* < 0.05, *F*$_{1,32}$ = 7.24 Fig. 4a). This finding was mainly governed by a CO$_2$-related increase of lactate at 8 °C (*p* < 0.05 in post hoc analysis) which led to detection of a significant interactive effect of temperature and CO$_2$ (*p* < 0.05, *F*$_{3,32}$ = 2.94). Interactive effects of temperature and CO$_2$ were also detected for choline and GABA (*p* < 0.05, *F*$_{3,32}$ = 5.870 and *p* < 0.05, *F*$_{3,32}$ = 4.033 Fig. 4b and c). For these substances post hoc tests revealed a significant CO$_2$-dependent increase at 8 °C (*p* < 0.05), which was absent at other temperatures.

As in *B. saida*, non-metric multidimensional scaling revealed for *G. morhua* that the vast majority of overall variance was explainable through temperature effects (*p* < 0.001, *R*$_2$ ~ 0.95, 10$^3$ permutations, Additional file 8: Figure S5), with only a minor contribution by CO$_2$ (*p* ~ 0.16, *R*$_2$ ~ 0.09, 10$^3$ permutations).

**Gadus morhua** - HPLC

As in *B. saida*, temperature significantly affected serotonin metabolism of *G. morhua* leading to a rise of the HIAA/5-HT ratio during warming (*p* < 0.05, *F*$_{3,31}$ = 3.394, Additional file 6: Figure S3b). Neither were effects of CO$_2$, nor interactive effects detected.

---

**Fig. 4** Boxplots depicting concentrations of metabolites affected by CO$_2$ (direct or interactive effects, relative to total creatine (tCr)) in the brain of *Gadus morhua* at different temperatures and CO$_2$ partial pressures. White shading indicates control, grey shading high CO$_2$ partial pressure. Each box contains median, first and third quartile as well as respective standard deviation. Different letters (a, b) indicate significant differences between treatment groups detected by Tukey HSD post hoc analysis (*p* < 0.05)
Discussion

Interference with anaesthesia
It cannot be fully excluded that additional factors such as the anaesthetic procedure may have an interactive effect with temperature or CO₂ contributing to the here presented observations. Effects of MS-222 on the respiratory and cardiovascular system of fish are well documented as well as the rapid MS-222 induced release of cortisol, changing inter alia the ionic composition of blood plasma [26, 27]. Consequences of MS-222 for intracellular osmolytes and neurotransmitter systems have not been reported and would demand further investigation.

Effect of temperature on brain metabolites
Temperature affected metabolite concentrations in the brain of Boreogadus saida and Gadus morhua in a very similar manner. The strongest alterations were visible among the osmolytes TMAO and MI, which fell in both species upon warming. This finding is in line with the view that TMAO and MI are cytoprotective in cold environments [28, 29]. In both species TMAO/tCr ratios reacted similarly to warming and underwent a reduction by ~ 70% from 3 °C to 8 °C. A striking difference was visible in the relative amount of TMAO, as at 3 °C and 8 °C the TMAO/tCr ratio in B. saida was around six-fold greater than the TMAO/tCr ratio of G. morhua, which indicates a greater importance of TMAO in physiological cold adaptation of B. saida. While temperature altered taurine concentrations in B. saida in a uneven manner, taurine decreased with increasing temperature in G. morhua. Osmolytes play a role in cytoprotection, and in both species elevated taurine concentrations may be beneficial below 8 °C [30] and may serve as compensation to the constitutive reduction of TMAO at temperatures above 0 °C. A decrease of osmolytes with increasing temperature was expected as high osmolarity in cold-adapted fish serves freezing point reduction [31]. In contrast, NAA levels increased in both species with increasing temperatures. In addition to its putative functions as osmolyte and potential energy reserve in neurons and oligodendrocytes, concentration changes of this substance might also have implications for membrane composition, as discussed below. However, not all osmotically active substances responded to temperature. Unlike Baslow and Guilfoyle [32] we did not detect temperature-related changes of acetylhistidine concentrations as observed in killifish (Fundulus heteroclitus) and goldfish (Carassius auratus). However, the temperature range investigated in this study (0 °C - 16 °C) was narrower than the range analysed by Baslow and Guilfoyle (13.3 °C - 30 °C).

In addition to their function as synaptic neurotransmitters, GABA, glutamate and glycine influence osmotic relations [33] which may explain why their concentrations decreased continuously with rising temperatures as observed in the prominent osmolytes as discussed above. This may explain the temperature dependence of glutamate and GABA in both species, and of glycine in G. morhua. Their concentrations decreased continuously with rising temperature. Windisch et al. found a strong temperature dependency in the expression of the glycine cleavage system in Antarctic eelpout, which was much higher expressed at cold temperatures below 0 °C indicating importance of glycine metabolism at low temperatures [34]. Whether the glycine cleavage system serves at low temperatures the catabolism of excessive glycine or rather its anabolism demands further experimentation. In B. saida, reductions of lactate, alanine, and glutamine levels occurred mainly between 6 °C and 8 °C, potentially indicating energy limitations at 8 °C as not only lactate, but also glutamate, glutamine, GABA are energy sources for the tricarboxylic acid (TCA) cycle in brain [35]. This hypothesis is supported by the fact that mortality of B. saida only occurred at 8 °C and that this temperature was recently identified to represent the long-term upper thermal tolerance limit for this species [22]. In B. saida, glycine concentrations were marginally reduced by increasing temperature, but the variance of concentrations between treatments fell with rising temperature, especially at 8 °C, potentially indicating energy limitations as well. A reduction of alanine levels at 8 °C in B. saida may not necessarily be a proxy for energy status, as G. morhua also exhibited a reduction of alanine level between 3 °C and 8 °C, but no further alteration of alanine concentrations was observed between 8 °C and 16 °C rather suggesting a temperature-dependent functioning of this amino acid as osmolyte.

Alterations of phosphocholine, glycerophosphocholine and putrescine with temperature may indicate structural changes in membrane metabolism and composition. Phosphocholine and glycerophosphocholine are intermediates of phosphatidylcholine metabolism and putrescine acts as progenitor for other polyamines such as spermidine and spermine, all of which are known to interact with membrane components [36–38]. Temperature-dependent changes in NAA levels as mentioned above might also indicate shifts in lipid metabolism to improve homeoviscous adaptation and oxygen supply. This substance also acts as the major donor of acetyl-groups for the myelinisation of neurons [39, 40].

Temperature had an effect on serotonin metabolism in both, B. saida and G. morhua, leading to higher HIAA/5-HT ratios at higher temperatures and indicating an increase of serotonin turnover. Similar results were observed in common carp by de Boeck et al., who suggested a Q₁₀ effect, but no stress response, as a mechanism [41]. In contrast to our findings, Sebert et al.
measured a reduced HIAA/5-HT ratio with rising temperature in the eel Anguilla anguilla [42], a finding which argues against a simple Q_{10} effect. However, serotonin is a modulator of respiration. Increased respiration through a risen O_2 demand at higher temperature may also be reflected in the HIAA/5-HT ratio [43].

Effect of CO_2 on brain metabolites in Boreogadus saida

CO_2 effects in B. saida were observed for the osmolytes MI and GABA. Interactive effects of temperature and CO_2 were detected for glutamate. All of these observations can mainly be attributed to alterations at 8 °C, where high CO_2 induced an increase in the concentrations of these three metabolites. These changes were quite small compared to temperature effects and were not significant in post hoc analysis. Additionally, CO_2 caused a transient (non-significant) rise of glutamine and glutamate at 8 °C accompanied by a non-significant reduction of NAA. We suggest that these findings are symptomatic for shifts in neural energy metabolism at 8 °C which might be exacerbated by CO_2. In mammals, NAA is coupled to the brain's energy metabolism and may serve as an anaplerotic source of acetate and aspartate [44]. While acetate can enter the TCA cycle after activation with SH-CoA through acetyl-CoA synthase [45], the remaining aspartate can be transformed to oxaloacetic acid and subsequently acetylated to citrate to enter the TCA cycle as well [44]. Also, in a second pathway, aspartate becomes deaminated to oxaloacetic acid generating glutamate from α-ketoglutaric acid. Glutamate, glutamine and GABA concentrations in the brain are tightly coupled through the glutamate/GABA-glutamate cycle [35].

An increase of GABA and glutamate might also indicate greater GABAergic activity at 8 °C and high CO_2, possibly reducing neuronal activity under limited energy conditions. After GABA release by inhibitory neurons, it is partly taken up by astrocytes and converted into succinate by GABA-transaminase and succinic semialdehyde dehydrogenase [46], simultaneously leading to the formation of glutamate from α-ketoglutaric acid. GABA is generated from glutamine via glutamate in neurons. This leads to an accumulation of ammonia, which is transported to astrocytes through the lactate-alanine shuttle [35]. Increased inhibitory activity of GABA is suggested to be responsible for the reduction of brain activity in response to hypercapnia in other vertebrates [47, 48]. A reduced neuronal energy demand may lead to an increase of lactate, as this metabolite serves as the favoured energy resource in neurons and is provided through glycolytic activity in astrocytes as part of the lactate-alanine shuttle [35]. An increase of lactate was not detected at 8 °C under high CO_2 in B. saida indicating no surplus of energy substrates. Anaplerotic reactions to refuel the TCA cycle and subsequent oxidative decarboxylation may be crucial for energy supply in cold-adapted species, as these possess only low glycolytic capacity [40]. Strobel et al. found a CO_2-induced reduction in succinate dehydrogenase activity in Notothenia rossi [21] and proposed an increased utilization of glutamate and aspartate in order to increase proton consuming decarboxylation processes, thereby supporting pH maintenance. We did not observe an increase in succinate levels at 8 °C in the high CO_2 group of B. saida, indicating no inhibition of succinate dehydrogenase. However, glutamate and aspartate catabolism as well as GABA synthesis may still contribute to acid-base regulation.

MI increments at 8 °C in the high CO_2 group remain enigmatic, but may serve as an alternative osmolyte to NAA in order to maintain osmolarity during NAA utilization. As CO_2-induced behavioural alterations in B. saida were not affected by environmental temperature [9], we assume that the detected CO_2-dependent metabolic changes at 8 °C are not the primary physiological cause of the CO_2-induced behavioural alterations observed in this species. As an alternative explanation, CO_2-dependent metabolic changes observed in B. saida at 8 °C may rather be symptomatic for temperature-induced energy limitation at 8 °C which is further exacerbated by environmental hypercapnia. The upper temperature limit of 8 °C detected by Kunz et al. in the animals used in this study supports this hypothesis [22]. Whether the observed generation of glutamate and GABA serve the formation of utilizable energy metabolites, the reduction of proton concentrations or indicate metabolic depression in order to reduce neuronal energy expenditures remains to be explored.

Effect of CO_2 on brain metabolites in Gadus morhua

In G. morhua, a CO_2-induced increase of lactate was detected mainly at 8 °C with an additional significant interactive effect of temperature and CO_2. Further interactions of CO_2 and temperature-effects were observed for GABA and choline due to an increase at 8 °C in the high CO_2 group. These changes occurred together with a non-significant increase of alanine, succinate, glutamate and glycine, while NAA remained largely unaffected. Although these findings seem somewhat similar to those in B. saida at 8 °C, we nevertheless suggest a different physiological causality involving increased GABAergic activity with unimpaired neuronal energy status. Simultaneous increases of succinate, alanine, glutamate and GABA might indicate an increased GABAergic activity as discussed above for B. saida; however, in G. morhua, the increase of GABA was detected with a simultaneous rise of lactate indicating an increase in the availability of this energy substrate. NAA as a marker of energy limitation displayed a non-significant trend to increase under
high CO₂, further indicating unimpaired energy status of the brain. Release of GABA and acetylcholine is coupled in some brain regions indicating an additional regulatory function of the latter [49–51] and might explain the significantly increased choline concentration. Interestingly, the high CO₂ group of G. morhua at 8 °C not only differed from the high CO₂ groups at other temperatures, but further displayed slightly reduced behavioural CO₂-effects as discussed in Schmidt et al. [9]. Our results indicate that resilience against CO₂-induced behavioural changes may be greatest in the middle of the thermal window; however, the mechanism behind this observation remains obscure.

GABA-metabolism and its putative role for CO₂-resilience

The question arises how an increase of GABAergic activity might protect the behaviour of fish, if altered GABA_A-receptor activity is responsible for the behavioural impairments under OA scenarios [2]. At least in mammals, neurophysiological consequences of GABA release are quite flexible and an excitatory function of GABA through GABA_A-receptor activity is already observed under normal conditions in the central nervous system [52]. Additionally, whether GABA is excitatory or inhibitory is dependent not only on the electrochemical gradient, but also on the timing and location of GABA release with respect to former excitatory postsynaptic potentials [52]. Thus, electrochemical acclimation or spatiotemporal adjustments of GABA release could sustain regular neuronal processing even under increased CO₂.

One possible alternative explanation arises from the point of view that concentrations of tissue CO₂ might be lower in the centre of an animal’s thermal window leading to increased resilience at optimum temperature. Studies allowing to address this hypothesis are scarce. Van Dijk et al. [53] found that CO₂ partial pressure in white muscle of Zoarces viviparus rises at temperatures below the thermal optimum for somatic growth of this species [54]. Experimental conditions may also have interfered as the seawater PCO₂ in the 8 °C high CO₂ group was slightly lower than in the other high CO₂ groups in Gadus morhua which should have led to a slightly lower tissue CO₂ partial pressure in animals of this specific treatment group. Nonetheless, animals under optimum temperature conditions may be able to maintain the inhibitory function of GABA even under increased CO₂. A simultaneous increase of GABAergic activity might lead to metabolic depression, as indicated by a simultaneous significant increase of lactate and GABA (Fig. 4a and c), and thus further reduction of tissue pCO₂ which might also increase relative reliance as ambient CO₂ rises. While the optimum temperature for growth in the animals used in this study is not known [22], Björnsson et al. found an optimum temperature of ~10 °C-12 °C for Icelandic cod fed ad libitum at similar body weight [55, 56]. The optimum temperature of G. morhua depends on several factors including life stage, food supply and population [57]. Limited food supply reduces the optimum temperature for somatic growth [56]. Since animals were not fed ad libitum in this study, 8 °C may thus have been close enough to their thermal optimum. In further studies, blood pCO₂ of cod under increased CO₂ conditions should be investigated over a broad temperature range in order to test this hypothesis and to correlate the findings with their CO₂ induced behavioural alterations.

Conclusion

In conclusion, a temperature increase has similar physiological consequences in both, Boreogadus saida and Gadus morhua with strong temperature dependent alterations particularly among osmolytes, membrane components and metabolites involved in GABA metabolism. The long-term thermal limit of B. saida may have been reached at 8 °C, with energetic constraints exacerbated by an increase of environmental CO₂. In G. morhua, no temperature-dependent alteration of the same metabolites has been observed indicating that the upper temperature limit had not been reached at 16 °C. Also, higher environmental CO₂ did not elicit energetic limitation in G. morhua. Interestingly, we found a significant CO₂ effect at 8 °C with a CO₂-induced increase of lactate, GABA and choline which could be associated with increased behavioural resistance of G. morhua at this temperature. Our data indicate that B. saida is more strongly affected than G. morhua by the concomitant warming and CO₂ increase expected to occur in the polar ocean until the end of the twenty-first century. In areas where the distribution of these species overlap, G. morhua might thus be more resilient to future OWA-related physiological challenges and might out-compete B. saida in the long term.

Acknowledgements

The authors are grateful to Jasmine Nahrgang (funded by the Polarisation grant of the Norwegian Research Council, no. 214184/F20) for providing us with the specimens of B. saida. Animal incubations were significantly supported by Silvia Hardenberg, Guido Krieten, Nils Koschnick, Sebastian Berger, Kristina Kunz and Elettora Leo. We want to thank Karim Zanaty, Marcel Machnik, Benjamin Matthey, Fredy Véliz Moraleda, Anette Tillmann, Isabel Ketelsen and Timo Hirse for measurements of DIC, pH, salinity and temperature throughout the incubation periods. Stephan Frickenhaus provided practical support for the multivariate analysis, his contribution is deeply appreciated.

Funding

This study was funded by the Federal Ministry of Education and Research (BMBF, Funding no. FKZ 03F0655B), Germany.

Availability of data and materials

The datasets acquired in this study are available in the Additional file 9: Raw data.

Authors’ contributions

MS, HP, HW, CB and DS developed the study design. MS conducted the incubation of the animals. Brains were sampled by MS and HW. SS conducted the NMR measurements with assistance of CB and MS. MS did the HPLC measurements with support of KL. Data analysis and statistical evaluation were performed by MS. All authors contributed to the interpretation of the results. MS drafted the manuscript which was subsequently edited by SS, KL, HW, HP, CB and DS. All authors read and approved the final manuscript.

Ethics approval

The experiments conducted were in accordance with the ethical standards of the federal state of Bremen, Germany, and were approved under reference number 522–27-11/02–00 (93).

Consent for publication

All authors gave final approval for publication.

Competing interests
