Dominance of the Nucleon Decay K-channels in $P_{LR}$

invariant $SO(10)$

May 1997

Abstract

RH rotations of the fermionic mass matrices are not observable in the standard
model, but dictate the details of the proton decay in GUTs. $P_{LR}$ symmetry in the two
light families leads to a full RH mixing. We give two versions of suitable broken $P_{LR}$
invariant $SO(10)$ which leads to nucleon decay modes similar to those of SUSY-GUTs
with rates in the range of observability of superKamiokande and ICARUS.
New results are expected in the near future from the proton decay experiments superKamiokande [1] and ICARUS [3]. This is the reason for a new wave of papers [4, 1] discussing proton decay, mainly in supersymmetric (SUSY) theories.

The decay of the proton was first predicted in the framework of Pati-Salam $SU_C(4) \times SU_L(2) \times SU_R(2)$ L-R symmetric gauge group [5] and $SU(5)$ GUT. The minimal $SU(5)$ which requires unification of the gauge coupling constants around $M_{SU(5)} \approx 10^{14}$ $GeV$ predicts gauge boson mediated proton decay, dominantly into $e^+\pi^0$ with a rate of 

$$\Gamma_{SU(5)}(P \rightarrow e^+\pi^0) \simeq 10^{-31\pm1} \text{ yrs}^{-1}.$$ 

At the same time the channel $P \rightarrow \nu K^+$ is strongly suppressed in conventional $SU(5)$ [6].

Both predictions of the $SU(5)$ GUT are now known to be inconsistent with experiment. The gauge coupling constants, as measured in LEP, do not unify in terms of conventional $SU(5)$ and the rate of $P \rightarrow e^+\pi^0$ is above the experimental upper limits [7]

$$\Gamma_{exp}(P \rightarrow e^+\pi^0) < \frac{1}{9} \times 10^{-32} \text{ yrs}^{-1}.$$ 

Making $SU(5)$ supersymmetric [8], which leads to unification of the LEP gauge coupling constants at the scale of $\approx 10^{16}$ $GeV$ [4], can solve these problems for an effective SUSY breaking below 1 $TeV$ [3]. The Yukawa unification $m_r(GUT) \simeq m_b(GUT)$ also works well in SUSY $SU(5)$ [5]. The high unification scale suppresses strongly the gauge boson mediated $D = 6$ proton decay in SUSY GUTs and avoids the above conflict with experiment. On the other hand, SUSY $SU(5)$ allows for $D = 5$ contributions to the proton decay via a color triplet Higgs exchange. In terms of the $SU_C(3)$ indices this $D = 5$ effective coupling reads

$$\epsilon_{ijk}q_iq_j\tilde{q}_k\ell.$$ 

(1)

The antisymmetry requires the contribution of at least two families and because the c-quark is too heavy the amplitude always involves an s-quark. Hence, $D = 5$ induced proton decay in SUSY theories is dominated by the Kaon–channels. The rate of the $D = 5$ contribution is in general much too high. It can however be reduced in certain models [3] using small mixing angles and coupling constants. One goes, in certain review papers, as far as saying that observations of Kaon–dominant proton decay will be a decisive evidence for SUSY.

In the meantime it was shown [10], that also in L-R symmetric GUTs like $SO(10)$ [11] or $E_6$ [12], the use of an intermediate breaking scale around $10^{11}$ $GeV$ [9] leads to gauge and Yukawa unification in a way similar to the SUSY GUTs. Also, as the scale of unification is higher, there is no problem here with the rate of $P \rightarrow e^+\pi^0$.

The aim of this paper is to show that if one makes the L-R symmetric GUTs $P_{LR}$ invariant, the corresponding non-SUSY GUTs also give proton decay results similar to the SUSY ones. In particular, they predict dominance of the proton decay K–channels with rates

\footnote{SUSY can also stabilize the hierarchy, obviously.}

\footnote{Note, that this scale is not arbitrary, it is relevant also for the axion window, the Baryon asymmetry and the RH neutrinos.}

1
in the range of observability by superKamiokande and ICARUS. The reason for this is
that \( P_{LR} \) invariance in the two light families will be shown to be equivalent to a full right-

handed (RH) mixing of these families and this practically leads to the exchange \( d^c \leftrightarrow s^c \) in
the proton decay amplitude. It is important to note here that, as long as the predictability
of the proton decay is considered, pure GUT models are more reliable than SUSY GUTs.

The proton decay in non-SUSY GUTs is induced by gauge bosons with known masses and
coupling. In SUSY-GUT models for proton decay there are, in contrast, many unknown
parameters. In particular, knowledge about the physics above the GUT scale is required
\[3\].

What is \( P_{LR} \)?

It is a local version of parity invariance. \( P_{LR} \) invariance under the product gauge group
\( G_L \times G_R \times P_{LR} \) means invariance under parity accompanied simultaneously by the exchange
of the groups \( G_L \leftrightarrow G_R \), or explicitly

\[
P_{LR} (i, k)_{LH} P_{LR}^{-1} = (k, i)_{RH}.
\]  

(2)

This is analogous to the “old” assignment of baryons to the \( P \) invariant representation
\( (\bar{3}, 3) \oplus (3, \bar{3}) \) under the global chiral \( SU_L(3) \times SU_R(3) \) \[3\]. The baryons then acquire
their masses when \( (\bar{3}, 3) \oplus (3, \bar{3}) \) is broken down to the diagonal group \( SU(3)_{L+R} \). Under
this diagonal group they constitute \( 8 + 1 \) Dirac spinors. However, while \( P \) invariance for
the global symmetry leads per definition to \( SU_L(3) \leftrightarrow SU_R(3) \) exchange, in the local case
\( G_{L,R} \) is only an historical notation. The chirality of the local currents is fixed by the
representation content of the fermions under \( G_{L,R} \). Therefore, the exchange \( G_L \leftrightarrow G_R \) is
an additional requirement for local gauge theories which completes the analogy with the
global case.

\( P_{LR} \) invariant local gauge theories were constructed first for leptons \[14\] and then for all
fermions in terms of \( SU_C(3) \times SU_L(3) \times SU_R(3) \) or \( E_6 \) \[15\].

It can also be applied to \( SO(10) \) \[16\] in terms of a L-R symmetric subgroup like the
Pati-Salam one.
The \( 16 \) fermionic family of \( SO(10) \) GUT transforms, in this case, under

\[
SO(10) \supset SU_C(4) \times SU_L(2) \times SU_R(2)
\]
as follows,

\[
16_{LH} = (4, 2, 1)_{LH} \oplus (\bar{4}, 1, 2)_{LH} \equiv f_{LH} + \bar{f}_{LH}
\]
and

\[
\overline{16}_{RH} = (\bar{4}, 2, 1)_{RH} \oplus (4, 1, 2)_{RH}.
\]

Applying \( P_{LR} \)

\[
(4, 2, 1)_{LH} \leftrightarrow (4, 1, 2)_{RH} \quad (\bar{4}, 1, 2)_{LH} \leftrightarrow (\bar{4}, 2, 1)_{RH}.
\]  

(3)

Hence, to have an \( SO(10) \otimes P_{LR} \) irreducible representation one needs two \( 16 \)'s. In fact,
using \( 16_{LH} \sim \overline{16}_{RH} \).
\[ \Psi_{16LH}^1 \oplus \Psi_{16LH}^2 \sim 16^1_{LH} \oplus 16^2_{RH} = (4,2,1)^1_{LH} + (\bar{4},1,2)^1_{LH} + (4,1,2)^2_{RH} + (4,2,1)^2_{RH} \quad (4) \]

Taking the families, \( i, j = 1, 2 \), into account, we then have

\[ P_{LR} f^i(x) P_{LR}^{-1} = \epsilon^j \sigma_2 \hat{f}^j(x) \quad (5) \]

The \( P_{LR} \) invariant Yukawa coupling mixes, therefore, the two \( SO(10) \) representations

\[ \mathcal{L}_Y = y_{12} \bar{\Psi}^c \phi_{12} \Psi^2 + y_{21} \bar{\Psi}^{2c} \phi_{21} \Psi^1 + h.c. \quad (6) \]

The relevant Higgs representations \( \Phi_{12}, \Phi_{21} \) transform under \( SO(10) \) like

\[ 16 \otimes 16 = (10 \oplus 126)_S \oplus 120_{AS} \]

In terms of \( SU_C(4) \times SU_L(2) \times SU_R(2) \) we need \( \Phi \sim (1,2,2) \) to have

\[ \bar{\Psi}^c \phi \Psi \sim (\bar{4},2,1) \otimes (1,2,2) \otimes (4,2,1) + \ldots \]

Such contributions are included only in the \( 10_S \) and \( 120_{AS} \) but not in \( 126_S \). Both symmetric and antisymmetric representations must be used to obtain non degenerate masses.

To make the model realistic, we have to introduce the third heavy family, together with the known LH mixing including CP violation and to explain the smallness of the neutrino masses. The last problem can be solved, as usual, by giving the RH neutrinos heavy Majorana masses when \( SO(10) \) will be broken down to the intermediate Pati-Salam gauge group.

Now, the third family is not directly involved in the proton decay. Its LH mixing with the light families is very small and CP violation will have a little effect only on the proton decay. So let us first discuss the two light families only and start with an exact \( P_{LR} \) symmetry.

The mass matrices must look as follows:

\[
\begin{pmatrix}
0 & m_d \\
m_e & 0 \\
\end{pmatrix}
\begin{pmatrix}
0 & m_d \\
m_e & 0 \\
\end{pmatrix}
\begin{pmatrix}
0 & m_e \\
m_\mu & 0 \\
\end{pmatrix}
\begin{pmatrix}
0 & m_\mu \\
m_\nu & 0 \\
\end{pmatrix}
\]

\[3^{\text{Note, that this form of the Yukawa Lagrangian can be fixed also by a discrete symmetry, independent of \( P_{LR} \).}} \]

\[4^{\text{which is not present in superstring inspired \( SO(10) \).}} \]
The diagonalization of these matrices obviously gives us a full RH mixing and vanishing LH mixing angles so that the physical families are then constructed as follows

\[ f^e = (4, 2, 1)_{LH}^1 \oplus (4, 1, 2)_{RH}^2 \sim (4, 2, 1)_{LH}^1 \oplus (\bar{4}, 1, 2)_{LH}^2 \]  

\[ f^\mu = (4, 2, 1)^2_{LH} \oplus (4, 1, 2)_{RH}^1 \sim (4, 2, 1)^2_{LH} \oplus (\bar{4}, 1, 2)_{LH}^1 \]  

Practically speaking, the RH components of the initial representations relevant for the proton decay are exchanged:

\[ u^c_{LH} \leftrightarrow c^c_{LH} \quad d^c_{LH} \leftrightarrow s^c_{LH} \quad e^c_{LH} \leftrightarrow \mu^c_{LH} \]  

The replacement of \( \hat{\nu}_e \leftrightarrow \hat{\nu}_\mu \) does not play a role for the proton decay as the RH neutrinos must be very heavy to induce the see-saw mechanism.

The RH mixing angles are not observable in the Standard Model (SM). This means that the pure diagonal and pure off-diagonal matrices are equivalent on the SM level. This is clearly not true on the GUT scale. In particular, the RH mixing plays an important role for the proton decay. Another GUT effect for which the RH mixing plays a major role is the Baryon asymmetry. Especially if it is included by leptogenesis [18], i.e. via decay of the heavy RH neutrinos.

The predictions of \( P_{LR} \) invariance for the proton decay are obtained making the replacement (9) in the conventional \( SO(10) \) effective Lagrangian [3]. Neglecting terms involving heavy fermions we then obtain

\[
\begin{align*}
\mathcal{L}_{\text{eff}} &= -\frac{4G}{\sqrt{2}} \epsilon_{\alpha\beta\gamma} [\bar{u}^c_{L \gamma} s^c_{L \gamma} d^\beta_{\mu R \gamma} \nu^\alpha_{\mu R \gamma} \lambda u^+_R] \\
&\quad + \frac{4G'}{\sqrt{2}} \epsilon_{\alpha\beta\gamma} [(\bar{s}^c_{L \gamma} d^\beta_{L \gamma} + \bar{d}^c_{L \gamma} s^c_{L \gamma}) \nu^\alpha_{\mu R \gamma} \lambda u^+_R - \bar{s}^c_{L \gamma} d^\beta_{L \gamma} \nu^\alpha_{\mu R \gamma} \lambda u^+_R] \quad , \quad (10)
\end{align*}
\]

where \( G = \frac{g^2}{2M_{X,Y}} \) and \( G' = \frac{g'^2}{2M_{X',Y'}} \) are the effective “Fermi coupling constants” for the \( SO(10) \) leptoquark gauge bosons \( X, Y \) and \( X', Y' \).

Clearly, only the following proton decay modes

\[ P \rightarrow \bar{\nu}_\mu K^+ \quad \text{and} \quad P \rightarrow \mu^+ K^0 \]

are possible. For the B-violating neutron decay eq. (10) gives only

\[ N \rightarrow \bar{\nu}_\mu K^0 \quad \text{and} \quad N \rightarrow \bar{\nu}_\mu K^{*0} . \]
We have not considered until now the observed family mixing, i.e. the Cabibbo angle. To take this into account we must break $P_{LR}$ invariance in the Yukawa Lagrangian (6). In this paper, however, we will discuss only the simplest possible perturbation of the above off-diagonal matrices that gives the LH Cabibbo mixing. This means adding a (2,2) element in the $M_d$ or the $M_u$ matrix such that the other matrices remain off-diagonal:

I) $M_u = \begin{pmatrix} 0 & m_u \\ m_c & 0 \end{pmatrix}$, $M_d = \begin{pmatrix} 0 & a \\ b & c \end{pmatrix}$, $M_e = \begin{pmatrix} 0 & m_e \\ m_\mu & 0 \end{pmatrix}$

II) $M_u = \begin{pmatrix} 0 & \alpha \\ \beta & \gamma \end{pmatrix}$, $M_d = \begin{pmatrix} 0 & m_d \\ m_s & 0 \end{pmatrix}$, $M_e = \begin{pmatrix} 0 & m_e \\ m_\mu & 0 \end{pmatrix}$

We will take the matrix elements to be real, in view of the previous remark on CP violation.

The requirement that the LH mixing will be the Cabibbo one then fixes also the RH mixing. E.g. for the above cases we find

I) $\tan \Theta^d_R = -\frac{m_d(\mu = 1GeV)}{m_s(\mu = 1GeV)} \cot \Theta_{Cabibbo} \simeq -0.228$

II) $\tan \Theta^u_R = \frac{m_u(\mu = 1GeV)}{m_c(\mu = 1GeV)} \cot \Theta_{Cabibbo} \simeq 0.017$

Note, that the $SO(10)$ model dictates the mass matrices at the GUT scale. Those masses must therefore be renormalized down to low energies. The mixing angles are, however, quite scale independent. This is related to the fact that the renormalization gives practically the same factor for the whole matrix. We shall use the masses at the scale $\mu = 1 GeV$ as it is usually done.

As we look for small deviations from the $P_{LR}$ invariant case, let us introduce the most general mixing of the quarks in the nucleon decay Lagrangian eq. (10).

\begin{align*}
u_{L,R} & = \cos(\alpha_{L,R})u_{L,R} + \sin(\alpha_{L,R})c_{L,R} \\
\ell_{L,R} & = -\sin(\alpha_{L,R})u_{L,R} + \cos(\alpha_{L,R})c_{L,R} \\
d_{L,R} & = \cos(\beta_{L,R})d_{L,R} + \sin(\beta_{L,R})s_{L,R} \\
s_{L,R} & = -\sin(\beta_{L,R})d_{L,R} + \cos(\beta_{L,R})s_{L,R}
\end{align*}

Using this and the Fierz-identities we can write $\mathcal{L}_{eff}$ in the form
\[ \mathcal{L} = A_1 \bar{u} c \gamma_L u e^+ \gamma_L d + A_2 \bar{u} c \gamma_L u e^+ \gamma_R d + A_3 \bar{u} c \gamma_L u \mu^+ \gamma_L d + A_4 \bar{u} c \gamma_L u \mu^+ \gamma_R d + A_5 \bar{u} c \gamma_L u e^+ \gamma_L s + A_6 \bar{u} c \gamma_L u e^+ \gamma_R s + A_7 \bar{u} c \gamma_L u \mu^+ \gamma_L s + A_8 \bar{u} c \gamma_L u \mu^+ \gamma_R s + A_9 \bar{u} c \gamma_L d \bar{c} \gamma_R d + A_{10} \bar{u} c \gamma_L d \bar{c} \gamma_R d + A_{11} \bar{u} c \gamma_L d \bar{c} \gamma_R s + A_{12} \bar{u} c \gamma_L d \bar{c} \gamma_R s + A_{13} \bar{u} c \gamma_L s \bar{c} \gamma_R d + A_{14} \bar{u} c \gamma_L s \bar{c} \gamma_R d + h.c. \]  

(15)

where \( \gamma_{L,R} = \gamma_{\mu}(1 \pm \gamma_5) \) and the \( A_i \) parameters are defined as follows:

\[
\begin{align*}
A_1 &= G \sin(\alpha_R + \alpha_L) \sin(\beta_L) - G \sin(\alpha_R + \beta_L) \sin(\alpha_L) \\
A_2 &= G \sin(\alpha_R + \alpha_L) \sin(\beta_R) - G' \sin(\alpha_L + \beta_R) \sin(\alpha_R) \\
A_3 &= -G \sin(\alpha_R + \alpha_L) \cos(\beta_L) + G \sin(\alpha_R + \beta_L) \cos(\alpha_L) \\
A_4 &= -G \sin(\alpha_R + \alpha_L) \cos(\beta_R) + G' \sin(\alpha_L + \beta_R) \cos(\alpha_R) \\
A_5 &= -G \sin(\alpha_R + \alpha_L) \cos(\beta_L) + G \cos(\alpha_R + \beta_L) \sin(\alpha_L) \\
A_6 &= -G \sin(\alpha_R + \alpha_L) \cos(\beta_R) + G' \cos(\alpha_L + \beta_R) \sin(\alpha_R) \\
A_7 &= -G \sin(\alpha_R + \alpha_L) \sin(\beta_L) - G \cos(\alpha_R + \beta_L) \cos(\alpha_L) \\
A_8 &= -G \sin(\alpha_R + \alpha_L) \sin(\beta_R) - G' \cos(\alpha_L + \beta_R) \cos(\alpha_R) \\
A_9 &= -G \sin(\alpha_R + \beta_L) \sin(\beta_R) + G' \sin(\beta_L + \beta_R) \sin(\alpha_R) \\
A_{10} &= G \sin(\alpha_R + \beta_L) \cos(\beta_R) - G' \sin(\beta_L + \beta_R) \cos(\alpha_R) \\
A_{11} &= G \sin(\alpha_R + \beta_L) \cos(\beta_R) - G' \cos(\beta_L + \beta_R) \sin(\alpha_R) \\
A_{12} &= G \sin(\alpha_R + \beta_L) \sin(\beta_R) + G' \cos(\beta_L + \beta_R) \cos(\alpha_R) \\
A_{13} &= -G \cos(\alpha_R + \beta_L) \cos(\beta_R) + G' \cos(\beta_L + \beta_R) \cos(\alpha_R) \\
A_{14} &= G \cos(\alpha_R + \beta_L) \sin(\beta_R) - G' \cos(\beta_L + \beta_R) \sin(\alpha_R)
\end{align*}
\]

(16)

Note, that here \( \alpha_R, \beta_R \) are the deviations from the full RH mixing, i.e.

\[
\alpha_R = \frac{\pi}{2} - \Theta_R^u, \quad \beta_R = \frac{\pi}{2} - \Theta_R^d .
\]

We will use the calculations done in \([16], [19]\) in terms of the \( SU(6) \) quark model of Gavela et al \([20]\). I.e. the partial rates of the different channels are given as follows

\[
\Gamma = \left[ \frac{M_P^5}{(10^{14})^4} \right] \left( \frac{10^{14}}{M_X} \right)^4 \rho 16\pi \alpha_U^2 \left[ \frac{|A_3|^2 |\psi(0)|^2}{M_P^4} \right] \left[ |A_1|^2 |\langle |M_L|^2 \rangle A_{12}^L|^2 + |A_2^L|^2 |\langle |M_R|^2 \rangle A_{12}^R|^2 \right]
\]

(17)

This expression depends on the \((X,Y),(X',Y')\) masses, the unification scale, \( M_U \) and the unification coupling constant of \( SO(10) \), \( \alpha_U \). \( M_U \) and \( \alpha_U \) were already calculated.
for $SO(10)$ broken down to the intermediate gauge group $SU_C(4) \otimes SU_L(2) \otimes SU_R(2)$ in several papers \cite{10}. As for $(X,Y)$ and $(X',Y')$, their masses are expected to be around $M_U$. Threshold effects may, however, lead to somewhat smaller $M_{x,y}$ or $M_{x',y'}$. To take this into account and to get an idea how much such threshold corrections effect the partial rates, we studied three possibilities:

\begin{align}
(i) \quad M_{x,y}^2 &= M_{x',y'}^2 = M_U^2 \\
(ii) \quad M_{x,y}^2 &= 10M_{x',y'}^2 = M_U^2 \\
(iii) \quad M_{x',y'}^2 &= 10M_{x,y}^2 = M_U^2
\end{align}

For $|\Psi(0)|^2$ we took \cite{21}:

$$|\Psi(0)|^2 = 0.012 \text{ GeV}^2.$$  

The phase space factor $\rho$ was estimated à la Karl and Kane \cite{22} as

$$\rho = (1 - \chi^2)(1 - \chi^4)$$

where

$$\chi = \frac{m_{\text{meson}}}{m_{\text{nucleon}}}.$$  

For $|A_{12}^{L,R}|$ we used \cite{23}

\begin{align}
|A_{12}^L|^2 &= \left[ \left( \frac{\alpha_2(M_Z^2)}{\alpha_U} \right)^{27} (86 - 8N_f) \right] \left( \frac{\alpha_1(M_Z^2)}{\alpha_U} \right)^{-69} \left( \frac{6}{6+40N_f} \right)^2 \tag{18} \\
|A_{12}^R|^2 &= \left[ \left( \frac{\alpha_2(M_Z^2)}{\alpha_U} \right)^{27} (86 - 8N_f) \right] \left( \frac{\alpha_1(M_Z^2)}{\alpha_U} \right)^{-33} \left( \frac{6}{6+40N_f} \right)^2 \tag{19}
\end{align}

The renormalization factor $A_3$ was calculated using

$$A_3 = \left( \frac{\alpha_s(\mu^2)}{\alpha_U} \right)^{6/(33-2N_f)} \tag{20}$$

where

$$\alpha_s(\mu^2) = (12\pi)/(25 \ln \frac{\mu^2}{\Lambda_{QCD}^2})$$

with $\Lambda_{QCD} = 324^{+20}_{-50} \text{ MeV}$ \cite{24}.

As was explained before we considered two possibilities to introduce the Cabibbo mixing into the $P_{LR}$ invariant formalism:
Case I) a (2,2) entry in $M_d$
and
Case II) a (2,2) entry in $M_u$.

The calculated branching ratios (BRs) for the proton decay can be found in tables 1, 2 and the ones for the neutron decay in tables 3, 4. In addition to the BRs in % we give the total nucleon decay rate in the different cases.

Considering the tables we see, as was expected, that in all versions (except for the Iii one) the Kaon decay channels dominate. This is especially true for the versions Iiii and Iii. All three versions of case (I) have a considerable rate for the channel

$$P \to e^+ K^0$$

The versions Ii and Iii also have a considerable contribution to the

$$P \to \bar{\nu}_\mu \pi^+$$

channel. The interesting "new" neutron decay mode is

$$N \to \bar{\nu}_\mu \omega$$

which is present in most versions.

The rates we calculated used the central values of the parameters, without taking into account all kind of corrections and in particular not the full threshold effects. Those corrections were estimated already in a paper of Lee et al \cite{28} for the standard $SO(10)$ broken down to Pati-Salam gauge group. They found

$$\tau_{P \to e^+ \pi^0} = 1.44 \times 10^{37.4\pm0.7\pm1.0^+0.5_{-5.0}} \text{ yrs}.$$  

Or explicitly,

$\pm0.7$ - comes from the proton decay matrix element evaluation \cite{3},

$\pm1.0$ - comes from uncertainty in the LEP data, while.

$\pm0.5_{-5.0}$ - in due to the threshold corrections.

This gives an idea of the possible corrections to the absolute rates given above. The branching ratios are, however, independent of those corrections. Taking those into account, it is clear that all the interesting decay modes fall into the range of observability of superKamiokande and ICARUS, i.e. $O(10^{34})$ yrs.

The versions with $G' \neq G$ have, however, essentially larger absolute rates (by a factor $\sim 100$) and have a better chance to be tested experimentally.

\footnote{It is interesting to note that this mode is also enhanced in the SUSY GUT model of ref. \cite{26}. In this SUSY model the two light families are also symmetric, they transform as 2 under the flavor $[S_3]^3$ symmetry.}
Table 1: Branching ratios and the total rate for proton decay channels in case (I) for the three different versions.

| channel          | $G' = \frac{1}{10}G$ | $G' = G$ | $G' = 10G$ |
|------------------|----------------------|----------|------------|
| $e^+\pi^0$      | 0                    | 0        | 0          |
| $e^+\eta$       | 0                    | 0        | 0          |
| $e^+\rho^0$     | 0                    | 0        | 0          |
| $e^+\omega$     | 0                    | 0        | 0          |
| $\bar{\nu}_e\pi^+$ | 5.7                  | 2.1      | 0.03       |
| $\bar{\nu}_e\rho^+$ | 0.3                  | 0.1      | 0.0        |
| $\mu^+K^0$      | 43.2                 | 16.6     | 1.3        |
| $\bar{\nu}_\mu K^+$ | 3.9                  | 1.4      | 0.02       |
| $e^+K^0$        | 0                    | 0        | 0          |

Table rate ($\text{yr}^{-1}$): 1.6 $10^{-33}$, 2.3 $10^{-35}$, 4.1 $10^{-34}$
The minimal models we considered here are not complete in the sense that the heavy family is not explicitly included. To introduce the third family while keeping the approximate $P_{LR}$ invariance for the two light families, there are two directions one can take:

a) To keep the special role of the top-family in getting its masses directly from the Higgs mechanism. Models of this kind assume that the three families transform as $2 \oplus 1$ under a family group like $O(3)$, $U(2)$ or $(S_3)^3$ [25], [26]. The “perturbations”, like radiative corrections or non-renormalizable terms, which give masses to the light families in those models must then be, in our case, (approximately) $P_{LR}$ invariant.

b) To use a very heavy fourth family which obeys also $P_{LR}$ invariance with the third one and has very small mixing angles with the light families. In this way one can obtain predictions for the masses of the very heavy fermions.

Those possibilities will be studied in detail in another paper [27]. Let us only mention here that in the case a) we have to start from $3 \times 3$ mass matrices of the form

\[
\begin{pmatrix}
0 & a & 0 \\
0 & b & 0 \\
0 & 0 & d
\end{pmatrix}.
\] (21)

It is natural then to look for nearest neighbour interactions (sometimes called non-hermitian Fritzsch matrices [29]) which give the right fermionic masses and Cabibbo-Kobayashi-Maskawa LH mixing angles. In the framework of the SM, a given mass matrix can always be transformed into a next neighbour interaction matrix [30], but on the GUT scale this will define the RH mixing angles that are relevant for nucleon decay.
