Abstract

Afferent loop obstruction is a purely mechanical complication that infrequently occurs following construction of a gastrojejunostomy. The operations most commonly associated with this complication are gastrectomy with Billroth II or Roux-en-Y reconstruction, and pancreaticoduodenectomy with conventional loop or Roux-en-Y reconstruction. Etiology of afferent loop obstruction includes: (1) entrapment, compression and kinking by postoperative adhesions; (2) internal herniation, volvulus and intussusception; (3) stenosis due to ulceration at the gastrojejunostomy site and radiation enteritis of the afferent loop; (4) cancer recurrence; and (5) enteroliths, bezoars and foreign bodies. Acute afferent loop obstruction is associated with complete obstruction of the afferent loop and represents a surgical emergency, whereas chronic afferent loop obstruction is associated with partial obstruction. Abdominal multiple detector computed tomography is the diagnostic study of choice. CT appearance of the obstructed afferent loop consists of a C-shaped, fluid-filled tubular mass located in the midline between the abdominal aorta and the superior mesenteric artery with valvulae conniventes projecting into the lumen. The cornerstone of treatment is surgery. Surgery includes: (1) adhesiolysis and reconstruction for benign causes; and (2) by-pass or excision and reconstruction for malignant causes. However, endoscopic enteral stenting, transhepatic percutaneous enteral stenting and direct percutaneous tube enterostomy have the principal role in management of malignant and radiation-induced obstruction. Nevertheless, considerable limitations exist as a former Roux-en-Y reconstruction limits endoscopic access to the afferent loop and percutaneous approaches for enteral stenting and tube enterostomy have only been reported in the literature as isolated cases.

Key words: Afferent loop; Obstruction; Reoperation; Endoscopy; Enterostomy
DEFINITIONS

Creation of a gastrojejunostomy leaves a segment of proximal small bowel, most commonly consisting of duodenum and proximal jejunum, lying upstream from the gastrojejunostomy. This limb of intestine conducts bile, pancreatic juices, and other proximal intestinal secretions toward the gastrojejunostomy and is termed the afferent loop[1]. Afferent loop obstruction (ALO) is a purely mechanical complication that infrequently occurs following construction of a gastrojejunostomy. The operations most commonly associated with this complication include total gastrectomy with loop esophagojejunostomy and simple anastomosis, the incidence of ALO after open and laparoscopic surgery is similar. Kim et al. in their retrospective cohort study, reported 4 (1.01%) patients who developed ALO among 386 gastric cancer patients submitted to laparoscopic distal gastrectomy with Billroth II reconstruction. The interval between the initial gastrectomy and the operation for ALO ranged from 4 to 540 d (median 33 d). The causes of ALO included adhesions in 2 patients and internal herniation in 2 patients. All patients recovered following emergency operations[11]. Aoki et al. in their retrospective cohort study, reported 4 (0.2%) patients who developed ALO among 1908 gastric cancer patients submitted to distal gastrectomy with Roux-en-Y reconstruction. The causes of the ALO included internal herniation in two patients, adhesions in one patient, and peritoneal recurrence in one patient. The interval between the initial gastrectomy and emergency operations for ALO ranged from 3 wk to 2 years (median 5 mo). All patients recovered following emergency operations.

There are limited data on the incidence of ALO after pancreaticoduodenectomy, especially among long-term pancreatic cancer survivors (>2 years). In one of the few studies in the literature, Pannala et al. evaluated the incidence of ALO in pancreatic cancer patients submitted to pancreaticoduodenectomy. Pannala et al. in their retrospective cohort study, reported 24 (13%) patients who developed ALO among 186 pancreatic cancer patients treated with pancreaticoduodenectomy. Median time to diagnosis was 1.2 years (range 0.03-12.3 years). Obstruction was primarily caused by recurrent pancreatic cancer in 8 patients (33%) and radiation enteritis of the afferent loop in 9 patients (38%)[13].

PATHOPHYSIOLOGY

Symptoms associated with ALO are attributed to the increased intraluminal pressure and distention due to accumulation of enteric, biliary and pancreatic secretions in the partially or completely obstructed afferent loop. The severity of symptoms mainly depends on the degree and duration of obstruction[14]. Acute ALO represents a closed-loop obstruction and can be complicated by: (1) Ischemia and gangrene of the completely obstructed afferent loop with subsequent perforation and peritonitis; and (2) Ascending cholangitis and pancreatitis. Chronic
ALO represents an open-loop obstruction and can be complicated by: (1) Events similar to those seen in closed-loop obstruction despite the fact that the partially obstructed afferent loop can be partially decompressed; (2) Ascending cholangitis and pancreatitis; and (3) Bacterial overgrowth which can lead to steatorrhea, malnutrition, and vitamin B-12 deficiency[^15].

**PRESENTATION**

The primary symptoms of patients with acute ALO are sudden, severe abdominal pain and vomiting. The pain often occurs before associated findings of localized abdominal tenderness and involuntary guarding develop. When physical findings develop, there is a high level of suspicion that the viability of the bowel is compromised. Consequently, when ALO is the most likely diagnosis, abdominal pain out of proportion to physical findings represents a surgical emergency. The vomitus is not bilious because the biliary and pancreatic secretions remain trapped in the obstructed afferent loop[^16].

Chronic ALO is more difficult to diagnose than acute ALO. Chronic ALO may manifest as periumbilical discomfort developing 15-30 min after eating and often lasting 1 to 4 h. These patients develop food fear and modify their pattern of eating so that they only consume a small quantity of food. Patients with chronic ALO almost always have a profound weight loss, which raises suspicion of intraabdominal malignancy. The progression from open-loop obstruction which is characterized by minor symptoms to closed-loop obstruction which represents a true surgical emergency is unpredictable. Projectile bilious vomiting may occur as the distended afferent loop decompresses forcefully providing rapid relief of symptoms. Chronic ALO with stasis and bacterial overgrowth can be further complicated by steatorrhea, diarrhea, B-12 and iron deficiency anemia[^17].

Physical examination can reveal one or more of the following findings: (1) Upper abdominal distention. An ill-defined mass in the upper abdomen may be palpated representing the completely obstructed afferent loop; (2) Localized upper abdominal tenderness and involuntary guarding if perforation and peritonitis have occurred; (3) Jaundice; and (4) Signs of pancreatitis.

**IMAGING STUDIES**

Prior to the era of CT, conventional upper gastrointestinal barium studies were used to assess ALO. Two classical findings of ALO were described: (1) Non-filling of the afferent loop; and (2) Retention of barium in the dilated afferent loop for at least 60 min. However, several limitations existed as 20% of normal afferent loops were not filled with a barium meal and the underlying cause of obstruction was poorly identified[^18].

CT plays a key role in the diagnosis of ALO. Zissin et al[^19] reported that the characteristic CT appearance of the obstructed afferent loop is a U or C-shaped, fluid-filled, 5.3 cm in average diameter, tubular mass (C-loop sign) located in the midline between the abdominal aorta and the superior mesenteric artery with valvulae conniventes projecting into the lumen (keyboard sign) which can help in the differential diagnosis of pancreatic pseudocysts. Juan et al[^20] reviewed multiple detector computed tomography scans of 22 patients who developed ALO after partial gastrectomy and pancreaticoduodenectomy. The C-loop appearance was present in 22 patients (100%) and the keyboard sign in 21 patients (95%) (Figure 1). There was only 1 patient without the presence of the keyboard sign due to bowel perforation. The maximal diameter of the afferent loop ranged from 3.3 to 5.8 cm.

CT images should be evaluated for the presence of: (1) the C-loop sign; (2) the keyboard sign; (3) pancreaticobiliary tract dilatation; (4) bowel wall thickening at the anastomotic sites, the afferent and efferent loops; and (5) lymphadenopathy, ascites, peritoneal enhancement, and metastatic lesions. Adhesions are suspected when a point of transition from a dilated to a normal-caliber loop is observed without other apparent cause. An internal hernia is suspected when crowding, stretching, and crossover of mesenteric vessels and the whirl sign are observed. Local recurrence and radiation enteritis are suspected when focal and diffuse bowel wall...
thickening are observed, respectively. Carcinomatosis is suspected when ascites and peritoneal enhancement are present and bowel wall thickening around the level of obstruction is absent[21]. Kim et al[22] reviewed helical CT scans of 18 patients who developed ALO after partial gastrectomy. The presumed cause of obstruction on CT was compared with surgical findings and clinical courses. In all 8 patients who underwent a second operation the cause of afferent loop was correctly suggested on CT. In all 10 patients who were not re-explored, the clinical findings or biopsy indicated recurrent tumor as suggested on CT. The authors concluded that CT correctly predicted the causes of ALO[22].

Diagnostic evaluation of ALO in the setting of a preceded pancreaticoduodenectomy should embrace magnetic resonance cholangiopancreatography (MRCP) or secretin-enhanced MRCP. The incidence of biliary and pancreatic stricture after pancreaticoduodenectomy is 2.6% and 2%, respectively. The patency of the primary hepaticojejunostomy and pancreaticojejunostomy should be thoroughly evaluated because the presence of a stricture can alter management strategy of ALO. Anatomic variants (pancreas divisum, dominant dorsal duct, aberrant ductal communications) and ductal pathology including filling defects, stenosis or obstruction should be recorded[23]. A hepaticojejunostomy stricture is characterized by the presence of a fixed filling defect at the anastomotic site, along with post-obstructive extra- and intra-hepatic ductal dilation. A pancreaticojejunostomy stricture is characterized by the presence of a fixed filling defect at the anastomotic site, along with post-obstructive ductal dilation, side-branch enhancement and/or decreased functional excretion into the jejunal drainage limb[24].

MANAGEMENT

As ALO is an infrequent complication after gastrectomy and pancreaticoduodenectomy, the literature on management of this complication is limited and much of the current knowledge is derived by the accrual of single-institution series. Management strategy (Table 2) depends on the following three factors: (1) The benign or malignant nature of the obstructing lesion. ALO caused by benign lesions needs definitive treatment by surgery with the exception of anastomotic ulcerations which can be managed by endoscopic balloon dilation. Surgery includes repair of the primary cause along with a form of afferent loop reconstruction including: Addition of a Braun anastomosis in a former Billroth II reconstruction, excision of the redundant loop and conversion of Billroth II to Roux-en-Y gastrojejunostomy, and excision of the redundant loop and reconstruction of the former Roux-en-Y jejunojejunostomy. ALO caused by malignant lesions needs primarily palliative treatment (percutaneous and endoscopic interventions, by-pass surgery) and secondarily surgery with curative intent (excision and reconstruction); (2) The site of obstruction. An obstruction at the inframesocolic portion of the afferent loop can be easily reconstructed, whereas an obstruction at the supramesocolic portion of the afferent loop needs copious mobilization of the supramesocolic segment of the afferent loop through a field of dense adhesions; and (3) The patency of the primary hepaticojejunostomy and pancreaticojejunostomy. ALO in the setting of a preceded pancreaticoduodenectomy may require revision of the hepaticojejunostomy and pancreaticojejunostomy and/or a modified Puestow procedure during reconstruction of the obstructed afferent loop due to an anastomotic stenosis demonstrated in the preoperative secretin-enhanced MRCP[25].

As mentioned above, surgery has the principal role in the management of benign ALO. On the contrary, palliative approaches are preferred in the setting of malignant ALO as in the literature there are no data showing differences in survival between patients who submitted to palliative and curative treatment for management of malignant ALO. Endoscopic interventions at the afferent loop (balloon dilation, double-pigtail stents traversing the afferent loop strictured area, balloon dilation and double-pigtail stent placement, afferent loop metal stent placement), the bile duct (biliary balloon dilation and plastic or metal stent placement through ERCP), and the pancreatic duct (pancreatic duct balloon dilation and stent placement through ERCP or EUS-guided rendezvous drainage after unsuccessful ERCP) have the principal role in the management of malignant ALO[26]. In Pannala et al[13] series, fifteen patients (62%) had an endoscopic intervention for management of malignant ALO after pancreaticoduodenectomy with Billroth II reconstruction for pancreatic cancer. These patients required a median of 2 endoscopic procedures (range 1-17 endoscopic procedures); eleven patients (73%) had clinical and laboratory improvement, two patients (13%) did not improve, and two patients (13%) were lost to follow-up[13]. However, a Roux-en-Y reconstruction limits endoscopic access to the afferent loop[27]. Enteral stenting and ERCP with double-balloon enteroscope in patients with Roux-en-Y anastomosis have only been reported in small single-institute series[28]. Moreover, transhepatic enteral stent insertion and direct percutaneous tube enterostomy for management of ALO have only been reported in the literature as isolated.

Figure 1 C-loop (black arrow) and the keyboard sign (white arrows).
MANAGEMENT OF AFFERENT LOOP OBSTRUCTION

**Table 2** Management of afferent loop obstruction

| Causes                  | Management                                                                 |
|-------------------------|-----------------------------------------------------------------------------|
| Benign                  | Endoscopy and balloon dilation of anastomotic stenosis or adhesiolysis, enterotomy, removal and repair of anastomotic stenosis (stricturoplasty, revision of the Roux-en-Y reconstruction) |
| Bezoar                  | Endoscopy and balloon dilation of anastomotic stenosis (stricturoplasty, addition of Braun anastomosis, conversion to Roux-en-Y reconstruction) |
| Foreign bodies          | Manual reduction or enterectomy and conversion to Roux-en-Y reconstruction |}
