KEYWORDS

Hepatocellular Carcinoma, Epigenetic Modification, DNMT1 Gene, Marveld1 Gene, Methylation, Proliferation
Abstract
Background To study the effect of DNA methyltransferase (DNMT1) on Marveld1 in hepatocellular Carcinoma (HCC), and explore its role in the molecular mechanism of HCC occurrence and development.

Methods The expression levels of Dnmt1 and Marveld1 genes were detected by RT-PCR in the intraoperative pathological specimens. The human hepatoma Bel7402 and SMMC7721 cell lines down-regulated by DNMT1 gene expression were constructed by SiRNA transfection. The methylation level of Marveld1 promoter region was detected after RT-PCR and West-blot verification. The expression of Marveld1 gene, cell proliferation, invasion and change of cell cycle were detected by RT-PCR and West-blot. The expressions of P53, CyclinD1, and P21 and P16 protein were detected by West-blot method.

Results The expression of DNMT1 gene in human hepatocarcinoma tissues was higher than that in adjacent tissues. The methylation level of the Marveld1 gene promoter region in human hepatoma cell line down-regulated by DNMT1 gene expression was decreased, the expression level of Marveld1 gene was increased, and the proliferation and invasion ability of cells were weakened. The cell cycle was showed as G1-S phase arrest; P53 and P16 protein expressions were up-regulated, and CyclinD1 and P21 protein expressions were down-regulated.

Conclusions Dnmt1 gene is highly expressed in human hepatocarcinoma tissues. Down-regulation of DNMT1 gene expression can decrease the methylation level of Marveld1 promoter region, up-regulate Marveld1 gene and human P53 and P16 proteins expressions, and down-regulate CyclinD1 and P21 proteins expressions, inhibit the proliferation and invasion of human hepatoma cells and can cause cell cycle G1-S arrest.

Background
Hepatocellular carcinoma (HCC) has become one of the most common malignant tumors worldwide. About 780,000 new cases of liver cancer occur each year, which accounting for 7.4% of all malignant tumors, and the mortality rate is about 9%. Statistics from IARC (International Agency for Research on Cancer) showed that HCC has become the fourth leading cause of cancer death in the world \[1\]. HCC
has a high degree of malignancy, which is easy for recurrence after surgery, and has poor prognosis. Therefore, exploring the causes of HCC and the molecular mechanism of its pathogenesis is of great value for its early diagnosis, treatment and prognosis. Existing studies have found that the occurrence of HCC is closely related to viral hepatitis, alcoholism, diet and cirrhosis, but the molecular mechanism of the disease still involves two aspects of genetic mechanism and epigenetic modification mechanism [2]. More and more evidence also indicates that epigenetic modification plays a very important role in the occurrence and development of HCC. In the study of epigenetic modification, DNA methylation research is one of the important fields of current research [3]. Studies have shown that hypermethylation inactivation of multiple tumor suppressor genes (Ecadherin, RASSF1A, GSTP, SOCS1, SFRP1, PTEN) in HCC is one of the important molecular mechanisms for the occurrence and development of HCC [4-6].

DNA methyltransferase (DNMT) plays a key role in DNA methylation. The methylation of genomic DNA mainly occurs on the cytosine of CpG Island, and methyl group is added to 5' end of the pyrimidine ring by the action of DNMT. The DNMTs family has approximately five members: DNMT1, DNMT2, DNMT3a, DNMT3b, and DNMT3L, of which DNMT1 is the most important DNA methylase and plays an important role in the maintenance of methylation status [7-8]. DNMT inhibitors have been used in a few fields such as myeloid leukemia, so the new treatment with DNMT as the entry point is a valuable direction in the field of HCC treatment.

Marveld1 (Marvel domain containing-1, MD1) gene is located in the long arm 2 region 4 band 2 subband of human chromosome 10 (10q24.2). The mRNA is 3238 bp in length and has two exons. The coding region is located in the first exons, and the encoded protein product consists of 173 amino acid residues with a molecular weight of approximately 18.9 kDa. Li et al [9] first reported the biological function of Marveld1 gene, and confirmed that it plays an important role in the regulation of malignant biological behavior of tumors in malignant tumors such as liver cancer [10] and lung cancer [11].

In order to study the effect of DNMT1 on Marveld1 in HCC, and explore its role in the molecular
mechanism of HCC occurrence and development, and then explore a new possible method for the
diagnosis and treatment of HCC, we use the method of SiRNA transfection to down-regulate the
expression of DNMT1 gene in human HCC cell lines, and its effect on HCC cells was studied.

Methods
Search the TCGA database
The expression difference of DNMT1 and Marveld1 genes in liver cancer and adjacent tissues and the
relationship between the expression difference and survival, the difference of methylation level of
Marveld promoter region, and the related genes of DNMT1 and Marveld1 genes were examined
respectively.

Cell culture
Human HCC Bel7402 and SMMC7721 cell lines were used, and DMEM medium (Gibco, Thermo Fisher
Scientific Suzhou Instrument Co., Ltd.) supplemented with 10% serum (Gibco, Grand Island, NY, USA)
was used at 37 °C - 5% CO2 incubator for cell culture.

Construction of transfected cell lines with down-regulated expression of Dnmt1
gene
SiRNA (Suzhou Gemma Gene) sequence:
Control group (Dnmt1-NC)
Positive-sense strand (5'-3'): UUCUCCGAACGUGUCACGUTT
Antisense strand (5'-3'): ACGUGACACGUUCGGAGAATT
Dnmt1 gene down-regulation group (Dnmt1-2505)
Positive-sense strand (5'-3'): GGGACUGUGUCUCGUUAUUTT
Antisense strand (5'-3'): AUAACAGAGACACAGUCCCTT.

Human HCC Bel7402 and SMMC7721 cells were evenly plated into 6-well plates and cultured for 24
hours. The cell density was about 50%. Premixed transfection solution was added to each well
(containing 75 pmol of SiRNA, 7.5 uL of lipofectamin2000, and 200 uL of Opti-MEM medium). Further
experiments were carried out after incubation for 48 hours at 37 °C - 5% CO2.

RT-PCR
From January 2017 to December 2017, 22 pairs of HCC and adjacent cancer tissue samples were
collected from the Affiliated Tumor Hospital of Harbin Medical University. All samples were preserved
in liquid nitrogen immediately after collection. All the samples were confirmed to be HCC by postoperative pathology. The written informed consent of the patients for the study was obtained before surgery. The intraoperative samples used in this study were approved by the medical ethics of the Human Experimental Committee of Affiliated Cancer Hospital of Harbin Medical University. 1 μg of total RNA was extracted from tissue samples and adherent cultured cell samples with trizol, and then reverse-transcribed into cDNA by reverse transcription kit, and detected by RT-PCR using a ViiATM7 real-time PCR instrument (Applied Biosystems).

Dnmt1 gene primer sequence:
Upstream 5'-AGGCGGCTCAAGATTTGGAA-3'
Downstream 5'-GCAGAAATTCGTGCAAGGATTC-3'

Marveld1 gene primer sequence:
Upstream 5'- ACTGAGAAGTCCCGCTGTTACAG -3'
Downstream 5'- GGGATGCTGGGAATCTTAAGG-3'

GAPDH Primer Sequence:
Upstream 5'-AGGCTGTGGGCAAGGTCATC-3'
Downstream 5'-TCAGGTCCACCACTGACACG-3'

The human hepatocellular carcinoma cell line with down-regulated expression of DNMT3a and DNMT3b was constructed using the SiRNA transfection method with the same expression of down-regulation of Dnmt1, and the sequence of SiRNA (Suzhou Gemma gene):

Dnmt-NC (control group)
Positive-sense strand (5’-3’): UUCUCCGAACGUGUCACGUTT
Antisense strand (5’-3’): ACGUGACACGUUCGGAGAATT

DNMT3a-SI
Positive-sense strand (5’-3’): CGGCUCUUCUUUGAGUUCUTT
Antisense strand (5’-3’): AGAACUCAAAGAAGCCGTT

DNMT3b-SI
Positive-sense strand (5’-3’): GUGAGGAACAUCAACAAAGATT
Antisense strand (5'-3'): UCUUUGUGAUGUCCUCACTT

RT-PCR was used to detect the down-regulation of DNMT3a and DNMT3b expression and the corresponding Marveld1 gene expression change.

DNMT3a Primer Sequence:
Upstream: 5'-CCGATGCTGGGGACAAGAAT -3'
Downstream: 5'-CCCGTCATCCACCAAGACAC -3'

GAPDH Primer Sequence:
Upstream: 5'- AGGCTGTTGGCAAGGTCATC-3'
Downstream: 5'-TCAGGTCCACCACTGACACG-3'

Marveld1 gene promoter region methylation level sequencing detection

The 1ug genomic DNA was extracted, and the bisulfite conversion and purification and collection were carried out according to the kit instructions (QIAGEN, No. 59824). The sequence of the Marveld1 gene promoter region was found in NCBI and designed the primers:

Upstream 5'-GCCAGGGCAAGCAGGAGGTGG-3'
Downstream 5'-CTGCTGAGACTAAGACGTGG-3'

After PCR amplification, the amplification products were sequenced to determine the methylation level of the Marveld1 gene promoter region, and the sequence and CpG island sites were as follows:

1CpG  2CpG  3CpG  4CpG  5CpG
CGAGTGGAACGAGTGCGGTGCCTGTGGGTGATGGACTCTTACTCCGACATGGTGTTAAACTCGGACAG
6CpG  7CpG  8CpG
Western-blot
Cell count: Taken the same number of cells and added with RIPA lysate (containing 5% Doc, 1% PMSF, 1% pepstatin A, 1% ribonuclease) at a concentration of 1×10⁶ cells/100μl, and after lysed at 4°C for 30 minutes, centrifuged at 12,000 rpm and then taken the supernatant protein solution. SDS-acrylamide gel electrophoresis was carried out and imprinted on a 0.2 um PVDF membrane. Washed with 0.1% PBST after sealed for 1 hour with 5% skim milk, and then immersed in 0.1% PBST diluted primary antibody overnight; washed with 0.1% PBST, and then immersed in secondary antibody for 1 hour, then washed with 0.1% PBST, and added with developer for development by ECL Western Blot Analysis System (Amersham Biosciences, Chalfont St. Giles, Buckinghamshire, UK), and grayscale analysis was conducted.

Measurement of cell proliferation ability by MTT assay
The cells were plated into the 96-well plates with 1500 cells/well, cultured and adherent with 200μl of DMEM medium, and then added 100μl of medium containing 10% MTT to each well at 0h, 24h, 48h, 72h and 96h, respectively, after cultured for 4 hours, 100μl of DMSO was added to each well, and the OD value was read at a wavelength of 450 nm by a micro plate after shaking. The 0hOD value was used as the baseline, and the ratio of the OD value at each time point to the OD value at 0h was the cell proliferation rate, and the proliferation curve of each group was plotted.

Changes of cell invasion ability after down-regulation of Dnmt1 gene expression was measured by Transwell method
The upper chamber of Transwell plate (3428, costar) was evenly spread with glue, and then spread with cells with 3×10⁵ cells/well in each well, and 1.5 ml of DMEM medium containing 0.5% serum was added, and 2.6 ml of medium containing 10% serum was added to the lower chamber; After cultured at 37°C -5% for 24 hours, photographs were taken under a crystal violet staining microscope. A total
of 4 visual fields were selected randomly from each group for counting.

Determination of Cell Cycle Changes after Down-regulation of Dnmt1 Gene Expression with flow cytometry

The cells were cultured in an adherent manner without EDTA trypsinization, and then the cells were collected after centrifugation, and after washed with PBS, the cells were fixed with 75% ethanol at 4 °C for 24 hours; then washed with PBS, PI staining was performed for 30 min, and the cell cycle was measured by flow cytometry after washing with PBS.

Statistical analysis

SPSS 17.0 statistical software was used for statistical analysis of each experimental result. The result data was expressed as X± s. P <0.05 was considered statistically significant.

Results

TCGA database search results

The search results of TCGA database showed that the expression of DNMT1 gene in HCC was higher than that in adjacent tissues, the expression of Marveld1 gene was lower than that in adjacent tissues (Figure 1A), and the methylation level of promoter region was higher than that of adjacent tissues (Figure 1B). The changes of expression of DNMT1 and Marveld1 gene were related with poor prognosis (Figure 1C). There is currently no data on the association between DNMT1 gene and Marveld1 gene expression.

Paired analysis of RT-PCR results of 22 clinical samples showed that the expression level of Dnmt1 gene in HCC tissues was higher than that in adjacent tissues, and the expression of Marveld1 gene in HCC tissues was lower than that in adjacent tissues (Figure 1D).

Construction of human HCC cell line with down-regulated Dnmt1 gene expression

After transfection with Si-RNA, the RNA and protein expression of Dnmt1 gene in the experimental group was significantly decreased (Figure 2A).

Detection of Marvel1 gene expression level

Detection of methylation level of Marveld1 gene promoter region

The 14 CpG islands in the promoter region of Marveld1 gene were sequenced, and the results showed the Bel7402 methylation CpGs rate in NC group was (57.1±2.38)% and (43.6±6.61)% in the SI group, and the SMMC7721 methylation CpGs rate in NC group was (40.7±2.14)% and (32.9±4.42)% in the SI
group; this result indicates that the number of methylation in human HCC cells with down-regulated Dnmt1 expression was lower than that in the control group, and the methylation level of the Marveld1 gene promoter region was decreased (Figure 2B and 2C).

Marveld1 gene expression detection

The RNA and protein expression of Marveld1 gene in human HCC cells with down-regulated Dnmt1 expression was up-regulated (Figure 3A, Figure 3B).

Changes of proliferative capacity of human HCC after down-regulation of Dnmt1 gene expression by MTT assay

In the experimental group, the cell proliferation ratio was higher than that of the control group in the 0h-96h time period; at 72h, the Bel7402 cell proliferation ratio in the NC group was (4.9670±0.1597) and (2.9676±0.3614) in the SI group; SMMC7721 cell proliferation ratio in the NC group was (3.2734±0.1394) and (2.5646±0.0789) in the SI group. After down-regulation of Dnmt1 gene expression, the proliferative capacity of human HCC was decreased significantly (Figure 3C).

Detection of the change of invasive ability of HCC cells after down-regulation of Dnmt1 gene expression by Transwell assay

The number of invading cells of Bel7402 in the NC group was (155.25±15.97) and (65.00±4.55) in the SI group; the number of SMMC7721 invasive cells in the NC group was (102.70±12.90) and (41.00±6.27) in the SI group. After down-regulation of Dnmt1 gene expression, the invasive ability of HCC cells was weakened (Figure 3D and 3E).

Detection of change of cell cycle after down-regulation of Dnmt1 gene expression by flow cytometry

After down-regulation of Dnmt1 gene expression, HCC cells were increase in G1 phase, and decreased in S phase, suggesting that down-regulation of Dnmt1 gene expression may cause cell cycle G1-S arrest in HCC cells (Figure 3F).

West-Blot detection of P53, CyclinD1, P21 and P16 protein expression

After transfection with Si-RNA, the expression of P53, P21 and P16 proteins was up-regulated, and the expression of CyclinD1 protein was down-regulated (Figure 4).

After transfection with Si-RNA, the RNA expression of DNMT3a and DNMT3b genes in the experimental group was significantly decreased (*p<0.05), Figure 5.
However, the Marveld1 gene of human hepatocytes with down-regulated DNMT3a and DNMT3b gene expression was not significantly changed compared with the Marveld1 gene of human hepatocytes with down-regulated DNMT1 gene expression. Therefore, human hepatocellular carcinoma cells with down-regulated DNMT1 gene expression were selected as experimental subjects (#p>0.05), Figure 6.

Discussion

DNMT, as the key factor in the regulation of DNA methylation in tumor tissues, can affect the biological behavior of tumor cells by regulating the degree of methylation of gene promoters with different functional. The DNMTs family has approximately five members: DNMT1, DNMT2, DNMT3a, DNMT3b, and DNMT3L, of which DNMT1 is the most important DNA methyltransferase and plays an important role in methylation status maintenance; deletion of DNMT1 may lead to decreasing of DNA methylation, affect the transcription of genes, and then regulate cell growth and differentiation.

Proteins containing the MARVEL domain are evolutionarily conserved and widely expressed in normal adult tissues. They involve a variety of biological processes, including cell cycle progression, chemotactic activity, tight junctions, and clathrin-mediated endocytosis. As a member of this family, the research on the molecular function of Marbeld-1 is limited so far. Studies have shown that the expression of Marveld-1 gene in liver cancer and lung cancer tissues is lower than that in adjacent tissues. Overexpression of Marveld-1 gene can inhibit the proliferation of tumor cells, up-regulate P53 and P16 genes, and can down-regulate the expression of CyclinD1 gene, Marveld-1 can affect the G1-S phase checkpoint-associated proteins of the cell cycle mentioned above, and then lead to G1-S phase arrest of Marveld-1 overexpressing cells, thus exert the function of tumor suppressor gene.

The data in the TCGA database showed that the DNMT1 gene was highly expressed in HCC tissues and low in Marveld1 gene, which was consistent with the clinical sample paired PCR results in this study. Marveld1 gene was hypermethylated in HCC tissues, and the survival of the samples with low expression of Dnmt1 gene was longer than that of the samples with high expression of Dnmt1 gene, suggesting that down-regulation of DNMT1 gene expression can up-regulate the expression of
Marveld1 gene, and the results of inhibiting the malignant biological manifestations of HCC may have potential clinical application value. There is no data on the relationship between Marveld1 gene and DNMT1 gene in TCGA database. This study showed that the down-regulation of Dnmt1 gene can up-regulate the expression of Marveld1 gene by down-regulating the methylation level of Marveld1 gene promoter region, and there is certain correlation between the expressions of two genes.

This study found that in human HCC tissues, the expression of Dnmt1 gene in HCC tissues was higher than that in adjacent tissues. Down-regulation of the expression of Dnmt1 gene in HCC cells could down-regulate the methylation level of the promoter region of Marveld1 gene. The expression of Marveld1 gene can be up-regulated by the epigenetic modification, and can inhibit the proliferation and invasion of HCC cells that consistent with the existed study on the overexpression of Marveld1 gene [10]. Up-regulated P53, P21 and P16 genes, down-regulated the expression of CyclinD1 gene, and affecting the G1-S phase checkpoint-associated proteins in the cell cycle, thus leading to G1-S phase arrest in cells. The Dnmt1 gene can change pathway, cause the epigenetic modification of the Marveld1 gene through a promoter methylation level, thus resulting in up-regulation of its expression and enhancing the function of the tumor suppressor gene.

Conclusions
DNMT inhibitors have been used in clinical applications, and the main therapeutic areas are bladder cancer and myeloid leukemia. The results of this study suggest that DNMT inhibitors may have some application prospects in the field of HCC at the in vitro cytological level, and related cells, animals and clinical trials may be a valuable research direction.

Abbreviations
DNMT: DNA methyltransferase; HCC: hepatocellular carcinoma; MD1: Marvel domain containing-1.
