Abstract. A class of exact propagators describing the interaction of an \( N \)-level atom with a set of on-resonance \( \delta \)-lasers is obtained by means of the Laplace transform method. State-selective mirrors are described in the limit of strong lasers. The ladder, \( V \) and \( \Lambda \) configurations for a three-level atom are discussed. For the two level case, the transient effects arising as result of the interaction between both a semi-infinite beam and a wavepacket with the on-resonance laser are examined.

PACS numbers: 03.75.Be, 03.75.-b, 31.70.Hq

The spacetime propagator can be considered as one of the most important tools in quantum physics for it governs any dynamical process. However, the knowledge of propagators corresponding to non-quadratic Hamiltonians is severely restricted. In this line, the spacetime propagator for a \( \delta \)-potential relevant to tunnelling problems has excited much attention \[1, 2, 3, 4, 5\]. Such interactions turn out to be particularly useful to gain physical insight in systems where only integrated quantities are to be considered. A thorough discussion of point interactions as solvable models using a functional approach can be found in \[6\], and a formalism to incorporate general point-interactions and dealing with different boundary conditions has been developed by Grosche \[7, 8\]. Even though the method is particularly suitable to calculate the energy-dependent Green function, a wide class of propagators was derived in such a fashion. The incorporation of time-dependent point-interactions has been possible through different approaches as Duru’s method \[9\] or the use of integrals of motion \[10\]. However, most of the effort has been focused on the dynamics of structureless particles and to the knowledge of the authors no attention has been paid to problems involving internal levels. Such state of affairs contrasts dramatically with the current surge of activity in atom optics.

In this paper we use the method of Laplace transform \[4, 5\] to tackle particles with internal structure. In particular, we shall focus on exact propagators for atom-laser interactions, namely, those of an atom interacting with a set of \( \delta \)-laser on-resonance with given interatomic transitions. The method is introduced in section \[1\] to obtain the exact propagator for a two-level atom. Details of the calculations relevant to the following sections are here provided. In section \[2\] the propagators for a ladder, \( V \), and \( \Lambda \) configuration (see Fig. \[1\]) of lasers interacting with a three-level atom are obtained. The
general case in which a given state is coupled to an arbitrary number of levels is discussed in section 3 where the high intensity limit of the laser is related to state selective mirrors. Such kind of systems presents manifold applications in laser coherent control techniques such as cold atomic cloud compression [11], atom mirrors and beam splitters [12], and different schemes where fast transitions are required as in the implementation of logic gates for ion trap quantum computing [13]. Moreover, idealised time-of-arrival measurements [14] and recently proposed improvements in Ramsey-interferometry with ultracold atoms [15] rest in a full quantum mechanical treatment of the dynamics of such systems.

1. The two-level atom

In this section, we use the method of Laplace transform to obtain the propagator for a two-level atom incident on a narrow perpendicular on-resonance laser beam. Spontaneous decay is assumed to be negligible throughout the paper and we shall consider effective one-dimensional systems in which the transverse momentum components can be neglected as it is the case for atoms in narrow waveguides [16]. In a laser adapted interaction picture, and using the rotating wave approximation, the Hamiltonian describing the system is

\[ H_c = \frac{\hat{p}^2}{2m} 1_2 + V \delta(\hat{x} - \xi) = \frac{\hat{p}^2}{2m} 1_2 + \frac{\hbar \Omega}{2} \delta(\hat{x} - \xi) \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \]  

(1)

where \( \hat{p} \) is the momentum operator conjugate to \( \hat{x} \), the ground state \( |1\rangle \) is in vector-component notation \( \begin{pmatrix} 0 \\ 1 \end{pmatrix} \), and the excited state \( |2\rangle \) is \( \begin{pmatrix} 1 \\ 0 \end{pmatrix} \). The second term in the right hand side defines the potential strength matrix \( V \) and \( 1_2 \) the two-dimensional identity matrix. Equation (1) may be regarded as the \( \epsilon \to 0 \) limit of a laser of width \( \epsilon \) and Rabi frequency \( \Omega_L \) keeping \( \Omega = \Omega_L \epsilon \) constant. \( \Omega_L \) here and in the following is chosen to be real. We start then by considering the free propagator for a one-channel problem on a Hilbert space of square integrable functions \( \mathcal{H} \) (see for instance [8]),

\[ K_0(x, t|x', 0) = \sqrt{\frac{m}{2\pi i\hbar}} e^{\frac{i m (x - x')^2}{2\hbar}}. \]  

(2)

In what follows we shall be interested in describing the dynamics of particles with two internal levels. The free propagator (\( \Omega = 0 \)) for states on the Hilbert space \( \mathcal{H} \otimes \mathbb{C}^2 \) is given by \( K_0(x, t|x', t') = K_0(x, t|x', t') 1_2 \), in the same interaction picture than (1). Moreover, \( \delta \)-type of perturbations can be generally taken into account using the method of Laplace transform [5] which assumes the unperturbed propagator to be known. More precisely, the full propagator can be related to the free one through the Lippmann-Schwinger equation [4, 5]

\[ K(x, t|x', t') = K_0(x, t|x', t') - \frac{i}{\hbar} \int_0^t dt'' \int_{-\infty}^{\infty} dx'' K_0(x, t|x'', t'') V(x'', t'') K(x'', t'')|x', t'. \]  

(3)

Given that the potential has the form of a point-interaction, the integral over \( x'' \) coordinates is straightforward. One can then take the Laplace transform with respect
to \( t \), which we denote with a tilde,

\[
\tilde{\mathcal{K}}(x, s|x', 0) = \tilde{\mathcal{K}}_0(x, s|x', 0) - \frac{\text{i}V_0}{\hbar} \left( \begin{array}{cc} 0 & \tilde{\mathcal{K}}_0(x, s|\xi, 0) \\ \tilde{\mathcal{K}}_0(x, s|\xi, 0) & 0 \end{array} \right) \tilde{\mathcal{K}}(\xi, s|x', 0), \tag{4}
\]

where we have made use of the convolution theorem \((\mathcal{L}[f(t)g(t)]) = \tilde{g}(s)\tilde{f}(s))\). By setting \( x = \xi \) it is explicitly found that

\[
\tilde{\mathcal{K}}(\xi, s|x', 0) = \left( \frac{1}{\text{i}V_0\hbar} \tilde{\mathcal{K}}_0(0, s|00) \right)^{-1} \tilde{\mathcal{K}}_0(\xi, s|x', 0). \tag{5}
\]

Next, we note the exact expression for the Laplace transform of the single-channel free propagator \( \tilde{\mathcal{K}}_0(x, s|x', 0) = \sqrt{\frac{m}{2\iota \hbar s}} e^{\sqrt{\frac{2m\iota}{\hbar}}|x-x'|} \), which becomes necessary for evaluating the inverse of the matrix. Combining (4) and (5) the Laplace transform of the exact full propagator is obtained, and taking the inverse transform one can find the spacetime propagator

\[
\mathcal{K}(x, t|x', 0) = \mathcal{K}_0(x, t|x', 0) - \frac{\text{i}V_0}{\hbar} \begin{pmatrix} I & J \\ J & I \end{pmatrix}, \tag{7}
\]

with

\[
I = \frac{m}{2\iota \hbar} \mathcal{L}^{-1} \left( \frac{e^{-\sqrt{\frac{2m\iota}{\hbar}}(|x-x'|+|\xi-x'|)}}{s - \text{i} \frac{mV_0}{2\hbar^2}} \right),
\]

\[
J = \frac{m}{2\iota \hbar} \mathcal{L}^{-1} \left( \frac{\text{i}V_0}{\hbar} \sqrt{\frac{m}{2\iota \hbar s}} \right) \left( \frac{e^{-\sqrt{\frac{2m\iota}{\hbar}}(|x-x'|+|\xi-x'|)}}{s - \text{i} \frac{mV_0}{2\hbar^2}} \right). \tag{8}
\]

Fortunately in our case, the resulting matrix element can be related after taking partial fractions with standard results \( \text{[17]} \) so that

\[
\mathcal{K}(x, t|x', t') = \mathcal{K}_0(x, t|x', t') - \frac{mV_0}{4\hbar^2} \sum_{\alpha=\pm} e^{\frac{mV_0}{\hbar^2}(|x-\xi|+|\xi-x'|)+\frac{\iota mV_0^2}{2\hbar^2}} \times \text{erfc} \left[ \alpha \sqrt{\frac{\iota mV_0^2 t}{2\hbar^3}} + \frac{1}{2} \frac{\iota mV_0^2}{\hbar t} (|x-\xi| + |\xi-x'|) \right] \begin{pmatrix} \alpha 1 \\ 1 \alpha \end{pmatrix}. \tag{9}
\]

A more compact expression can be obtained rewriting the full propagator in terms of the Moshinsky function (see Appendix A),

\[
\mathcal{K}(x, t|x', t') = \mathcal{K}_0(x, t|x', t') - \frac{mV_0}{2\hbar^2} \sum_{\alpha=\pm} M \left( \alpha, \beta, \frac{\gamma}{\iota \hbar t} \right) \begin{pmatrix} \alpha 1 \\ 1 \alpha \end{pmatrix}, \tag{10}
\]

with \( \kappa = -\iota mV_0/\hbar^2 \) for short. One should notice that this propagator opens up the way to a whole variety of problems involving quantum dynamics of two-level atoms. A most relevant fact is that as long as the full Hamiltonian can be written as a direct sum, the same property holds for the propagator. Therefore, if \( \mathbf{H} = \bigoplus_{s=1}^d \mathbf{H}_s \),

\[
\mathcal{K}(x, t|x', t') = \bigoplus_{s=1}^d \mathcal{K}_s(x, t|x', t'), \tag{11}
\]
Exact propagators for atom-laser interactions

\[ \hat{p}^2 = \frac{\hbar^2}{2m_1} + \mathbf{V} \delta(\hat{x} - \xi) = \frac{\hbar^2}{2m_1} \mathbf{1}_3 + \frac{\hbar}{2} \delta(\hat{x} - \xi) \begin{pmatrix} 0 & \Omega_{12} & 0 \\ \Omega_{12} & 0 & \Omega_{23} \\ 0 & \Omega_{23} & 0 \end{pmatrix}. \]

Following section 1 one finds

\[ \mathbf{K}(x, t| x', t') = \mathbf{K}_0(x, t|x', t') - \frac{i}{\hbar} \mathcal{L}^{-1} \left[ \mathbf{K}_0 \mathbf{V}(x, s|\xi, 0) \left( 1_3 + \frac{i}{\hbar} \mathbf{K}_0 \mathbf{V}(0, s|0, 0) \right)^{-1} \mathbf{K}_0(\xi, s|x', 0) \right]. \]

Plugging the explicit form of the free propagator evaluated at the different positions, taking partial fractions, working out the inverse Laplace transform and rewriting the result in terms of the Moshinsky function, one finds the exact expression for the full propagator to be

\[ \mathbf{K}(x, t|x', t') = \mathbf{K}_0(x, t|x', t') \mathbf{1}_3 - \frac{m}{2\hbar^2} \sum_{\alpha=\pm} M \left( |x - \xi| + |\xi - x'|, -i\alpha \frac{\sqrt{V_{12}^2 + V_{23}^2}}{\hbar^2}, \frac{\hbar t}{m} \right) \times \begin{pmatrix} \alpha V_{12}^2 \\ V_{12} \sqrt{V_{12}^2 + V_{23}^2} \\ \sqrt{V_{12}^2 + V_{23}^2} \sqrt{V_{23}^2 + V_{23}^2} \end{pmatrix} \cdot \begin{pmatrix} V_1 \\ \alpha V_{12} V_{23} \sqrt{V_{12}^2 + V_{23}^2} \\ \sqrt{V_{23}^2 + V_{23}^2} \end{pmatrix} \cdot \begin{pmatrix} V_2 \\ \alpha V_{12} V_{23} \sqrt{V_{12}^2 + V_{23}^2} \\ \sqrt{V_{23}^2 + V_{23}^2} \end{pmatrix}. \]

\[ \mathbf{K}(x, t|x', t') = \mathbf{K}_0(x, t|x', t') \mathbf{1}_3 - \frac{m}{2\hbar^2} \sum_{\alpha=\pm} M \left( |x - \xi| + |\xi - x'|, -i\alpha \frac{\sqrt{V_{12}^2 + V_{23}^2}}{\hbar^2}, \frac{\hbar t}{m} \right) \times \begin{pmatrix} \alpha V_{12}^2 \\ V_{12} \sqrt{V_{12}^2 + V_{23}^2} \\ \sqrt{V_{12}^2 + V_{23}^2} \sqrt{V_{23}^2 + V_{23}^2} \end{pmatrix} \cdot \begin{pmatrix} V_1 \\ \alpha V_{12} V_{23} \sqrt{V_{12}^2 + V_{23}^2} \\ \sqrt{V_{23}^2 + V_{23}^2} \end{pmatrix} \cdot \begin{pmatrix} V_2 \\ \alpha V_{12} V_{23} \sqrt{V_{12}^2 + V_{23}^2} \\ \sqrt{V_{23}^2 + V_{23}^2} \end{pmatrix}. \]

which becomes very useful when one wishes to study the dynamics in a given subspace. In sections 4 and 5 we shall focus on some analytical examples dealing with the quantum dynamics of semi-infinite beams and wavepackets of 2-level atoms.

2. The three level atom

The procedure to obtain the propagator can be extended to atoms of many-levels. Even though the general expression can be found, the calculation is straightforward up to the inverse Laplace transforms. In this section we consider a three-level atom subjected to two on-resonance lasers in different configurations (see Fig. 1). First, we shall focus on the ladder configuration which involves the transitions $|1\rangle \to |2\rangle$ and $|2\rangle \to |3\rangle$ by means of lasers located at the same position. The Hamiltonian describing the system is then

\[ H_c = \frac{\hbar^2}{2m_1} \mathbf{1}_3 + \mathbf{V} \delta(\hat{x} - \xi) = \frac{\hbar^2}{2m_1} \mathbf{1}_3 + \frac{\hbar}{2} \delta(\hat{x} - \xi) \begin{pmatrix} 0 & \Omega_{12} & 0 \\ \Omega_{12} & 0 & \Omega_{23} \\ 0 & \Omega_{23} & 0 \end{pmatrix}. \]

Following section 1 one finds

\[ \mathbf{K}(x, t|x', t') = \mathbf{K}_0(x, t|x', t') - \frac{i}{\hbar} \mathcal{L}^{-1} \left[ \mathbf{K}_0 \mathbf{V}(x, s|\xi, 0) \left( 1_3 + \frac{i}{\hbar} \mathbf{K}_0 \mathbf{V}(0, s|0, 0) \right)^{-1} \mathbf{K}_0(\xi, s|x', 0) \right]. \]

Plugging the explicit form of the free propagator evaluated at the different positions, taking partial fractions, working out the inverse Laplace transform and rewriting the result in terms of the Moshinsky function, one finds the exact expression for the full propagator to be

\[ \mathbf{K}(x, t|x', t') = \mathbf{K}_0(x, t|x', t') \mathbf{1}_3 - \frac{m}{2\hbar^2} \sum_{\alpha=\pm} M \left( |x - \xi| + |\xi - x'|, -i\alpha \frac{\sqrt{V_{12}^2 + V_{23}^2}}{\hbar^2}, \frac{\hbar t}{m} \right) \times \begin{pmatrix} \alpha V_{12}^2 \\ V_{12} \sqrt{V_{12}^2 + V_{23}^2} \\ \sqrt{V_{12}^2 + V_{23}^2} \sqrt{V_{23}^2 + V_{23}^2} \end{pmatrix} \cdot \begin{pmatrix} V_1 \\ \alpha V_{12} V_{23} \sqrt{V_{12}^2 + V_{23}^2} \\ \sqrt{V_{23}^2 + V_{23}^2} \end{pmatrix} \cdot \begin{pmatrix} V_2 \\ \alpha V_{12} V_{23} \sqrt{V_{12}^2 + V_{23}^2} \\ \sqrt{V_{23}^2 + V_{23}^2} \end{pmatrix}. \]

Figure 1. Different configurations of a three-level atom interacting with a pair of on-resonance fields: a) ladder, b) $V$, and c) $\Lambda$ type.
Another relevant case is the V configuration in which a pair of lasers couples the state $|1\rangle$ with both $|2\rangle$ and $|3\rangle$ levels, in such a way that the resulting Hamiltonian is given by

$$H_c = \frac{\hat{p}^2}{2m} 1_3 + \frac{\hbar}{2} \delta(\hat{x} - \xi) \begin{pmatrix} 0 & \Omega_{12} & \Omega_{13} \\ \Omega_{12} & 0 & 0 \\ \Omega_{13} & 0 & 0 \end{pmatrix}. \quad (14)$$

The exact propagator can be found to be

$$K(x, t|x', t') = K_0(x, t|x', t') 1_3 - \frac{m}{\hbar^2} \sum_{\alpha=\pm} M \begin{pmatrix} |x - \xi| + |\xi - x'|, -i\alpha m \frac{\sqrt{V_{12}^2 + V_{13}^2}}{\hbar^2}, \frac{\hbar t}{m} \end{pmatrix} \times \begin{pmatrix} \alpha \sqrt{V_{12}^2 + V_{13}^2} & V_{12} & V_{13} \\ V_{12} & \sqrt{V_{12}^2 + V_{13}^2} & \frac{\alpha V_{13} V_{23}}{\sqrt{V_{12}^2 + V_{13}^2}} \\ V_{13} & \frac{\alpha V_{13} V_{23}}{\sqrt{V_{12}^2 + V_{13}^2}} & \sqrt{V_{13}^2 + V_{23}^2} \end{pmatrix}. \quad (15)$$

From the mathematical point of view such configuration is actually very similar to Λ scheme described by the Hamiltonian

$$H_c = \frac{\hat{p}^2}{2m} 1_3 + \frac{\hbar}{2} \delta(\hat{x} - \xi) \begin{pmatrix} 0 & 0 & \Omega_{13} \\ 0 & 0 & \Omega_{23} \\ \Omega_{13} & \Omega_{23} & 0 \end{pmatrix}. \quad (16)$$

whose propagator reads

$$K(x, t|x', t') = K_0(x, t|x', t') 1_3 - \frac{m}{\hbar^2} \sum_{\alpha=\pm} M \begin{pmatrix} |x - \xi| + |\xi - x'|, -i\alpha m \frac{\sqrt{V_{13}^2 + V_{23}^2}}{\hbar^2}, \frac{\hbar t}{m} \end{pmatrix} \times \begin{pmatrix} \frac{\alpha V_{13}^2}{\sqrt{V_{13}^2 + V_{23}^2}} & \frac{\alpha V_{13} V_{23}}{\sqrt{V_{13}^2 + V_{23}^2}} & V_{13} \\ \frac{\alpha V_{13} V_{23}}{\sqrt{V_{13}^2 + V_{23}^2}} & \frac{\alpha V_{23}^2}{\sqrt{V_{13}^2 + V_{23}^2}} & \frac{\alpha V_{23}^2}{\sqrt{V_{13}^2 + V_{23}^2}} \\ V_{13} & \frac{\alpha V_{23}^2}{\sqrt{V_{13}^2 + V_{23}^2}} & \frac{\alpha V_{23}^2}{\sqrt{V_{13}^2 + V_{23}^2}} \end{pmatrix}. \quad (17)$$

One may then study the space-time dynamics of coherent trapping which results from the destructive quantum interferences between the two transitions, for initial states in a superposition of the two lower levels $|1\rangle$ and $|2\rangle$. [18]

3. The N-level atom

In this section we extend the previous approach to an N-level system living on $\mathbb{C}^N$. Suppose that an N-level atom is subjected to the action of N on-resonance lasers ($\hbar \Omega_{ij}/2 = V_i$) all of which are located at the same position and couple the $|j\rangle$ level ($1 \leq j \leq N$) with the $(N-1)$ levels as shown in Fig. [2].
Exact propagators for atom-laser interactions

Figure 2. Configuration of a $N$-level atom interacting with a $(N - 1)$ on-resonance fields coupling the $|j\rangle$ to any other level.

\[ H_c = \frac{p^2}{2m} 1_N + \frac{\hbar}{2} \delta(x - \xi) \]

\[
\begin{pmatrix}
0 & \cdots & 0 & \Omega_{ij} & 0 & \cdots & 0 \\
\vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & \cdots & 0 & \Omega_{j-1,i} & 0 & \cdots & 0 \\
\Omega_{ij} & \cdots & \Omega_{j-1,i} & 0 & \Omega_{j+1,i} & \cdots & \Omega_{N,j} \\
0 & \cdots & 0 & \Omega_{j+1,i} & 0 & \cdots & 0 \\
\vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & \cdots & 0 & \Omega_{N,j} & 0 & \cdots & 0 \\
\end{pmatrix}
\]

(18)

Simplified configurations can be obtained just by setting certain coupling elements to zero. The exact propagator for such system reads

\[ K(x, t | x', t') = K_0(x, t | x', t') 1_N - \frac{m V_m^{-1}}{2 \hbar^2} \sum_{\alpha = \pm} M \left( |x - \xi| + |\xi - x'|, -i \alpha m \frac{V_m}{\hbar^2} \frac{\hbar t}{m} \right) \]

\[
\begin{pmatrix}
\alpha V_1^2 & \cdots & \alpha V_1 V_{j-1} & V_1 V_m & \alpha V_1 V_{j+1} & \cdots & \alpha V_1 V_N \\
\vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\
\alpha V_{j-1} V_1 & \cdots & \alpha V_{j-1} V_{j-1} & V_{j-1} V_m & \alpha V_{j-1} V_{j+1} & \cdots & \alpha V_{j-1} V_N \\
V_1 V_m & \cdots & V_{j-1} V_m & \alpha V_m^2 & V_{j+1} V_m & \cdots & V_N V_m \\
\alpha V_{j+1} V_1 & \cdots & \alpha V_{j+1} V_{j-1} & V_{j+1} V_m & \alpha V_{j+1} V_{j+1} & \cdots & \alpha V_{j+1} V_N \\
\vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\
\alpha V_N V_1 & \cdots & \alpha V_N V_{j-1} & V_N V_m & \alpha V_N V_{j+1} & \cdots & \alpha V_N^2 \end{pmatrix},
\]

(19)

where $V_m = \sqrt{\sum_{i \neq j} V_i^2}$. Incidentally, the ladder configuration in which only successive levels are coupled to each other, does not admit a similar generalisation to $N$-level given the complexity of the inverse matrix.

3.1. Intense lasers and propagators for state-selective mirrors

For the one-channel case, the effect of an infinite strength of the $\delta$-potential is tantamount to a hard-wall boundary condition [5, 19]. This feature has been extensively exploited in the exact perturbation theory developed by Grosche to obtain a wide class
of Green functions and propagators including boundaries (say, in half-space or boxes) [7,8]. In atom optics, it is also well-known that a very intense laser behaves as a totally reflective mirror for the states coupled by it. Therefore, we shall consider the limit in which one of the lasers is made infinitely strong. In order to do so, it is convenient to note that the following relation holds [5],

$$\lim_{V_j \to \infty} \frac{mV_j}{\hbar^2} M \left( |x - \xi| + |\xi - x'|, -i\alpha m \sqrt{\frac{\sum_{i=1}^{N} V_i^2}{\hbar^2}}, \hbar t \right) = \alpha K_0 \left( |x - \xi| + |\xi - x'|, 0, 0 \right).$$

The general expression for the propagators with \(N\)-lasers in which the \(n\)-th one (coupling the states \(|j\rangle \) and \(|n\rangle\)) is made infinitely strong becomes diagonal,

$$[K(x, t|x', t')]_{ik} = K_0(x, t|x', t') \delta_{ik} - K_0 \left( |x - \xi|, t \right| |x' - \xi|, t') \delta_{ik} (\delta_{jk} + \delta_{nk}),$$

(20)

\(\delta_{ij}\) being the Krönecker delta. The laser behaves then as a totally reflecting mirror selective to the sates coupled by it, and suppresses for such states any possible excitation due to the presence of other lasers located at the same position.

Another interesting case is the on-resonance excitation of a couple of levels with high-intensity lasers. This leads to the limit where the strength coefficients of the two lasers go to infinite, \(V_l, V_n \to \infty\) and \(n > l\), but its ratio is kept constant, \(V_l/V_n = c\) with \(c > 0\). For such case one finds

$$[K(x, t|x', t')]_{ik} = -K_0 \left( |x - \xi|, t \right| |x' - \xi|, t' \right) \frac{c}{\sqrt{1 + c^2}} (\delta_{ni} \delta_{lk} + \delta_{li} \delta_{nk})$$

$$+ \delta_{ik} \left[ K_0(x, t|x', t') - K_0 \left( |x - \xi|, t \right| |x' - \xi|, t' \right) \left( \delta_{kj} + \frac{c^2}{\sqrt{1 + c^2}} \delta_{lk} + \frac{1}{\sqrt{1 + c^2}} \delta_{nk} \right) \right].$$

(21)

The difference now arises from the fact that the state-selective mirrors have a finite reflectivity for states \(|l\rangle\) and \(|n\rangle\), to which excitation is allowed. However, notice that for the \(|j\rangle\) state the laser still mimics a totally reflecting mirror.

4. Moshinsky shutter

We next study a time-dependent multi-channel scattering problem and consider a monochromatic beam of two-level atoms in its ground-state incident on a totally absorbing shutter which is suddenly removed at time \(t = 0\). Such kind of setup is usually referred to as a Moshinsky shutter, ever since the seminal paper [20] which led to the discovery of diffraction in time. The conditions on the reflectivity of the shutter can be easily modified to more general cases [20,21]. The initial state is then of the form

$$\Psi(x, t = 0) = e^{ikx} \Theta(-x)|1\rangle,$$

(22)

where \(\Theta(x)\) is the Heaviside step function. Equation (22) is an obvious generalisation of the Moshinsky type of initial condition for a single-channel problem, discussed in the context of diffraction in time. We note that such kind of state is not normalisable in
Figure 3. Probability density of the ground and excited states, total probability density in the presence of the laser and for the free case, 50 ms after removing the shutter initially located at 50 \( \mu \text{m} \). The incident beam moves at \( v = 1 \text{ cm/s} \) (mass of \( ^{87}\text{Rb} \)). The picture is taken at the instant in which the classical profile (the step function \( \Theta(vt - x) \)) reach the laser.

the usual sense, yet accurately describes certain experimental setups \[22\] and provides a basis for wavepacket analysis.

The time evolution can be studied using the superposition principle. If we consider first the free evolution, with \( \Omega = 0 \), then the result is that of diffraction in time,

\[
\Psi_0(x, t) = \int_{-\infty}^{\infty} dx' K_0(x, t|x', t') \Psi(x, t = 0)
\]

\[
= M(x, k, \hbar t/m)|1\rangle. \tag{23}
\]

This solution was found by Moshinsky and has been observed in a wide variety of experiments with ultracold neutron interferometry for the one-channel case \[22\]. It is a well-known fact that it tends with increasing time to the stationary wavefunction. We further notice that due to the absence of coupling between the internal states in \( K_0(x, t|x', t') \), the excited state \( |2\rangle \) is not populated, in agreement with \( |1\rangle \).

An alternative configuration in which the beam tunnels through a \( \delta \)-barrier was discussed in \[21, 23, 24\].

Let us now look at the time evolution in the presence of the laser. Using the integral (A.4) in Appendix A the exact solution can be found in close-form,

\[
\Psi(x, t) = \int_{-\infty}^{\infty} dx' K(x, t|x', t') \Psi(x, t = 0)
\]

\[
= \Psi_0(x, t) + \frac{1}{2} \sum_{\alpha = \pm} \left( \frac{\kappa}{1} \right) \frac{1}{k - \alpha \kappa} \times \left\{ M(|x - \xi| + \xi, k, \hbar t/m) - M(|x - \xi| + \xi, \alpha \kappa, \hbar t/m) \right\}. \tag{24}
\]
Figure 4. Total probability density for an incident beam in the ground state with the laser and for free space, 150 ms after removing the shutter initially located at 100 µm. The incident beam moves at $v = 1$ cm/s (mass of $^{87}$Rb), exhibiting interference for all $x < \xi$, as a result of the reflection from the laser.

Figure 5. Space-time density plot of the population in the excited state, $|\langle 2 | \Psi \rangle|^2$, with $v = 1$ cm/s, and the position of the laser $\xi = 200$ µm. The grey scale changes from dark to light as the function values increase.

The total probability density is plotted in Fig. 4. The velocity of the incident beam is chosen in all simulations to satisfy $v = \hbar q/m = V_0/\hbar$, for which one finds, after solving the two-channel stationary problem, that the reflection and transmission probabilities in the excited state, $|R_2|^2 = |T_2|^2$, are maximised and indeed equal those in the ground state, $|R_1|^2 = |T_1|^2 = 1/4$. The paradigmatic oscillations on the probability density, main feature of the diffraction in time described by the Moshinsky function ($|\Psi_0|^2$), is modified for all $x < \xi$ due to the interference which arises with the reflected part. Indeed, for later times such interference completely dominates and the density profile is dramatically perturbed as shown in Fig. 4.
In Fig. 5 we plot the time evolution of the probability density in the excited state $|2\rangle$. The delta laser is shown to behave as a point-like source of atoms. Moreover, the pattern exhibits diffraction in both time and space domain.

5. Wavepackets dynamics

Many experiments deal with finite samples rather than beams. In the one-channel case, the tunnelling dynamics of wavepackets through narrow barriers have been examined in a series of works \[4, 19, 25\]. In addition, the phenomenon of quantum deflection was predicted in the presence of semi-transparent and perfect mirrors \[26, 27, 28\].

We next consider normalisable states belonging to $L^2(\mathbb{R}) \otimes \mathbb{C}^2$. In particular we study the dynamics of eigenstates of a hard-wall trap which are released at time $t = 0$ and launched with momentum $\hbar q$ against the on-resonance delta laser. All-optical box traps have been recently been obtained in the laboratory \[29\]. More precisely we assume an initial sine-wavepacket given by

$$
\Psi(x, t = 0) = \frac{1}{2i} \sqrt{\frac{2}{L}} \sum_{\beta = \pm} \beta e^{iq_n \beta x} \chi_{[0, L]} |1\rangle
$$

with $q_n = q + \beta n \pi / L$. The expansion of such state has recently been discussed at the single-channel level in free space \[30\], in the presence of gravity \[31\], and when generalised to the many-body Tonks-Girardeau regime \[32\]. For the interaction with the on-resonance delta laser one can actually propagate in time this initial condition.

The time evolved wavefunction is

$$
\Psi_0(x, t) = \int_{-\infty}^{\infty} dx' K_0(x, t|x', t = 0) \Psi(x', t' = 0)
$$

$$
= \frac{1}{4i} \sqrt{\frac{2}{L}} \sum_{\beta = \pm} \beta [e^{iq_n \beta x} M(x - L, q_n \beta, \hbar t / m) - M(x, q_n \beta, \hbar t / m)] |1\rangle
$$

(26)

and,

$$
\Psi(x, t) = \Psi_0(x, t) + \frac{1}{4i} \sqrt{\frac{2}{L}} \sum_{\alpha, \beta = \pm} \left( \frac{\alpha}{1} \right) \frac{\beta \kappa}{k - \alpha \kappa}
$$

$$
\times \left\{ e^{ip_\alpha L / \hbar} [M(|x - \xi + \xi - L, k, \hbar t / m) - M(|x - \xi + \xi - L, \alpha \kappa, \hbar t / m)] - [M(|x - \xi + \xi, k, \hbar t / m) - M(|x - \xi + \xi, \alpha \kappa, \hbar t / m)] \right\}.
$$

(27)

Figure 6 shows the dynamics when the incident momentum is such that maximum excitation is achieved. The laser acts as a beam splitter dividing the wavepacket into two parts, the transmitted one being similar in shape to the freely evolving wavepacket, whereas the reflected part exhibits interference. Notice that (24) and (26) admit a simple generalisation for the respective $N$-level problem. In order to do so it suffices to consider the suitable momenta and prefactor of the matrix in the propagator for each of the channels.
Figure 6. Ground, excited and total probability densities for an incident sine-wavepacket ($n = 1$) released at $t = 0$ from a hard wall trap of size $L = 50 \mu m$ and centered at $25 \mu m$ from the origin, with $q = mV_0/h$ and velocity $1 \text{cm/s}$, after $100 \text{ms}$ of evolution. The position of the laser is $\xi = 100 \mu m$. The freely time evolved sine wavepacket is also plotted.

6. Discussion

We have generalised the method of Laplace transform to include point-like perturbations in the dynamics of particles with internal structure. In such a fashion we have obtained the spacetime propagator for an $N$-level atom interacting with a set of on-resonance delta lasers. For strong lasers, the propagators for state-selective mirrors have been obtained. A similar procedure could be applied to the Green function for which an exact perturbation theory has been developed and extensively discussed by Grosche [8]. In the 3-level atom case, the ladder, V, and Λ configuration have been considered. The inclusion of time dependence in the propagators to adiabatically turn the lasers on and off independently from each other is an open problem which would provide access to the space-time dynamics of coherent population trapping and other relevant phenomena [18]. The dynamics of a semi-infinite beam and a wavepacket of two-level atoms incident on the laser, with a straightforward generalisation for the $N$-level case, have also been worked out.

Acknowledgments

Appendix A. The Moshinsky function

The Moshinsky function arises in most of the problems where 1D quantum dynamics involves sharp boundaries well in time or space domains. Similarly it is found when considering free propagators perturbed with point-interactions.

Its standard definition reads

\[ M(x, k, \tau) := e^{i\frac{k^2}{2} \tau} w(-z), \quad (A.1) \]

where

\[ z = \frac{1 + i}{2} \sqrt{\tau} \left( k - \frac{x}{\tau} \right), \quad (A.2) \]

and the so called Faddeeva function [33] \( w \) is explicitly defined as

\[ w(z) := e^{-z^2} \text{erfc}(-iz) = \frac{1}{i\pi} \int_{\Gamma_-} du \frac{e^{-u^2}}{u - z}, \quad (A.3) \]

\( \Gamma_- \) being a contour in the complex \( z \)-plane which goes from \( -\infty \) to \( \infty \) passing below the pole. After [20], \( M(x, k, \tau) \) has been named the Moshinsky function.

For the exact time evolution in the presence of a laser with a cut-off plane wave or hard-wall eigenstates as initial conditions, we find integrals of the form

\[ \int dx' e^{ikx'} M(ax' + b, c, \tau) = \frac{e^{ikx}}{i(k + ca)} [M(ax + b, c, \tau) - M(ax + b, -k/a, \tau)]. \quad (A.4) \]

For more details we refer the reader to [4].
