ABSTRACT

Lycopene is one of the six major dietary and serum carotenoids, and a potent antioxidant and anti-inflammatory agent. A large and growing body of scientific evidence supports the role of lycopene in multiple areas of health, including cancer, prostate, cardiometabolic, lung, skin, and liver health, and elucidates lycopene’s mechanisms of action. This paper provides an overview of several benefit areas, specifically prostate, testes, cardiovascular, liver and skin health.

Keywords
Lycopene; Carotenoids; Cardiovascular disease (CVD); Human health.

INTRODUCTION

Carotenoids are naturally occurring, generally fat-soluble pigments synthesized by plants, algae, and photosynthetic bacteria. Over 750 carotenoids are found in nature and 1,117 are catalogued in the Carotenoids Database. Carotenoids are responsible for the yellow, orange, and red colors in nature. Of the 40-50 carotenoids found in the human diet, lycopene is among the 6 most common dietary carotenoids, including α-carotene, β-carotene, β-cryptoxanthin, lutein, and zeaxanthin. These are grouped into provitamin A carotenoids (α-carotene, β-carotene, β-cryptoxanthin) and non-provitamin A carotenoids (lycopene, lutein, and zeaxanthin). Lycopene contains 11 conjugated double bonds and undergoes cis-trans isomerization through light, thermal energy and chemical reactions.

Lycopene is in the orange-red fruits and vegetables, such as tomatoes, papayas, red peppers, pink grapefruit, and watermelons. The highest natural concentration is found in gac fruit, from a tropical vine in Southeast Asia. Tomatoes and tomato-based products, such as ketchup, tomato juice, tomato paste and tomato sauce, provide at least 80% of dietary lycopene in western countries such as the United States. The average daily consumption of lycopene in the western world is 5-7 mg. Lycopene from highly processed tomatoes is more bioavailable than that from raw tomatoes. Cooking and processing help release the lycopene from its plant matrix and convert lycopene from its natural straight (trans) structure to a more bioavailable geometric (cis) isomer, because lycopene is fat soluble, dietary fat improves absorption.

Since the human body cannot synthesize lycopene, it must be consumed in the diet or taken as a dietary supplement. A significant portion of intact lycopene is absorbed by humans, which circulates through and accumulates in the liver, plasma and other tissues. Lycopene is first emulsified and solubilized into micelles before absorbed into the intestinal mucosa, then transported with other dietary lipids via chylomicrons through the lymphatic system to the blood. Lycopene is the most predominant carotenoid in the plasma and concentrates in low-density and very-low-density lipoprotein fractions of serum due to its lipophilic nature. Lycopene is found in most human tissues with preferential accumulation in the testes, adrenal glands, liver and prostate.

Major health problems nowadays deal with the accumulation of reactive oxygen species (ROS) accompanied with abnormalities, such as inflammation and irregular lipid metabolism, that are the primary risk factor for the increased prevalence of lifestyle metabolic diseases. ROS, also called free radicals, are highly reactive, unstable molecules that contain oxygen, and a build-up of these may cause damage to deoxyribonucleic acid (DNA), ribonucleic acid (RNA), and proteins, and ultimately may cause cell death. With 11 conjugated double bonds, lycopene is one of the most potent antioxidants and free radical scavengers with stronger antioxidant properties than other serum carotenoids. Lycopene has the highest singlet oxygen quenching rate of the carotenoids, specifically twice that of β-carotene and 10 times greater than...
α-tocopherol.\textsuperscript{36,37} By reducing the burden of ROS and oxidative stress, lycopene has been shown to prevent oxidative damage to lipids, proteins and cells.\textsuperscript{3,38}

**PROSTATE HEALTH**

Prostate cancer is the second most frequently diagnosed cancer in men globally and the fifth leading cause of death worldwide.\textsuperscript{29} In the United States, after skin cancer, prostate cancer is the second most common cancer in men, accounting for 9.5% of all new cancer cases.\textsuperscript{30,31} The primary risk factors are obesity, age, and family history. Positive prostate health outcomes have been associated with dietary intake of tomatoes, tomato-based products and lycopene supplementation, and lycopene blood levels.\textsuperscript{32-35} In a dose-response meta-analysis of lycopene and prostate cancer research, Chen, et al demonstrated that higher lycopene consumption between 9 and 21 mg/day and higher circulating levels of lycopene between 2.17 and 85 μg/dL were associated with a reduced risk of prostate cancer.\textsuperscript{36} Both lycopene supplementation (15 mg/d for 6-months) and consumption of lycopene-rich foods for 6-months have been shown to increase mean lycopene (1.28× and 1.42× higher, respectively, compared to placebo) in men with elevated prostate-specific antigen (PSA) levels.\textsuperscript{36} Circulating pyruvate levels are associated with an increased risk of prostate cancer.\textsuperscript{37} Lycopene supplementation (15 mg/d for 6-months) decreased circulating pyruvate levels in men with elevated PSA levels.\textsuperscript{37}

Oxidative stress plays a role in prostate cancer by increasing ROS and cancer cell proliferation, thus causing somatic DNA mutations and increased angiogenesis.\textsuperscript{38} In addition to its ability to quench free radicals, lycopene may reduce the risk of prostate cancer by additional mechanisms. Lycopene impacts intercellular communication modulation and the alteration of intracellular signaling pathways,\textsuperscript{39} which include an upregulation in intercellular gap junctions,\textsuperscript{40} an increase in cellular differentiation,\textsuperscript{41} and alterations in phosphorylation of some regulatory proteins.\textsuperscript{42} Physiological concentrations of lycopene have been shown to inhibit cell line proliferation in combination with α-tocopherol\textsuperscript{43} and lycopene was shown to inhibit prostate cancer cell proliferation via PPAR-LXRα-ABCA1 pathway.\textsuperscript{44} Lycopene attenuates the risk of prostate cancer by modulating the expression of growth and survival associated genes, e.g. CDK7, BCL2, EGFR, and IGF-1R.\textsuperscript{45} Multiple lycopene doses showed significant improvement in survival rate of and significant reduction of tumor volume in mice injected with prostate cancer cell lines.\textsuperscript{46}

**Male Infertility**

Infertility affects an estimated 70 million people globally,\textsuperscript{46} where male infertility contributes to 50% of the cases, according to the World Health Organization (WHO). Evidence suggests that oxidative stress caused by excessive amounts of ROS plays a role in idiopathic male infertility.\textsuperscript{47} This results in sperm membrane lipid peroxidation, DNA damage, and apoptosis leading to decreased sperm viability and motility.\textsuperscript{48} Lycopene concentration in testes is significantly lower in infertile men.\textsuperscript{49} Supplementation has been shown to increase seminal plasma lycopene,\textsuperscript{50} and lycopene may

| AUTHORS | POPULATION | LYCOPENE DOSE | RESULTS |
|---------|------------|--------------|---------|
| Aly H et al.\textsuperscript{36} | Wistar rats 4mg/kg bw, 16 days | Lycopene group significant ↑ sperm count and concentration (p<0.05) Within group significant ↑ ejaculate volume, total sperm count, concentration and motility Significant ↑ TAC (p<0.05) |

| Lane JA et al.\textsuperscript{36} | 133 human men 50-69 years with elevated PSA 15mg (capsules, blinded), lycopene-rich foods, unblinded, 6 months | ↑ mean lycopene 1.28x higher in capsule and 1.42x higher in food than placebo |
play a role as an antioxidant in the process of spermatogenesis.39

Multiple lycopene supplementation studies have shown promising results in reducing male infertility in both human and animal models. Results include a decrease in lipid peroxidation and DNA damage, an increase in sperm count and viability, and general immunity.40 Lycopene has been shown to reduce lipid peroxidation.41,42 Lycopene increases sperm count.41,43-48

Daily supplementation of 4-8 mg lycopene improves sperm motility,49,50 which was also shown in animal studies.49,50 Daily supplementation with 14 mg lactolycopene, a combination of lycopene with whey protein, was shown to improve sperm motility and morphology in young healthy men.50 Durairajanayagam et al concluded that daily 4-8 mg lycopene supplementation for 3-12-months is sufficient to treat male infertility.51,52,53 Supplementation of 20 mg/d lycopene for 3-months prior to in vitro fertilization (IVF) treatment resulted in 7 spontaneous pregnancies prior to treatment and 15 pregnancies post treatment and a significant improvement in docosahexaenoic acid (DHA)/arachidonic acid (AA) ratio in seminal plasma.54

A significant increase in transient aplastic crisis (TAC) (Table 1).55

**CARDIOVASCULAR HEALTH**

Cardiovascular disease (CVD) is the leading cause of mortality worldwide. Key risk factors include high blood pressure, high cholesterol and smoking. Damage and remodeling of blood vessels can result in blood flow restrictions affecting the heart and central nervous system in CVD, and atherosclerosis is the leading cause of CVD.56

Evidence suggests that Mediterranean countries have lower risks of CVD mortality when compared to other regions of Europe and the United States.57 This effect has been attributed to a diet rich in vegetables, including tomatoes, tomato products and olive oil.57 While low plasma levels of lycopene have been reported in hypertension, myocardial infarction, stroke, and atherosclerosis,58 dietary intake and high serum concentration of lycopene significantly reduced the risk of major cardiac events.59,60 In addition, epidemiological studies support the role of lycopene in the prevention of cardiovascular disease.61

Oxidative stress plays a significant role in cardiovascular disease62-64 and may be a major cause of lycopene depletion in ageing and cardiovascular disease.65 Low carotenoid levels, especially decreased serum lycopene levels, were shown to be strongly predictive of all-cause mortality and poor outcomes of CVD.66 Daily lycopene supplementation has been shown to increase serum lycopene concentration67 and reduce oxidative stress markers and improve antioxidant status.68

Anti-inflammatory mechanisms of lycopene include the decrease of adhesion molecules and pro-inflammatory cytokines, inhibition of leukocyte migration and genes involved in inflammation, impaired monocyte-endothelium interaction, T-lymphocytes activation, synthesis of advanced glycation products (AGE) and their receptors (RAGE), and down-regulation of cyclooxygenase 2.69 Lycopene inhibited the expression of ICAM-1, TNF-α induced NFkB activation and interaction between monocytes and endothelial cells.70 Serum lycopene was inversely associated with VCAM-1 and LDL.71 Kim et al showed lycopene supplementation improved microvascular function, measured by decreased concentrations of sVCAM and sICAM, a reduction in DNA damage, and an increase in superoxide dismutase (SOD) activity.72 Lycopene was shown to reduce the synthesis of AGE,

| Zheng Z et al.80 | T2DM rats | 0, 5, 10, 15mg/kg Lycopene, 10 wks | Dose dependent ↑oxidative stress markers (GHb, ox-LDL, and MDA) and inflammatory factors (TNF-α and CRP) | ↑TAC (CAT,SOD, and Gpx) |
down regulating their receptors (RAGE) which contributes to vessel protection. Lycopene reduced inflammatory markers in various animal models.

Lycopene improves endothelial function by increasing the bioavailability of nitric oxide (NO), improving endothelium-dependent vasodilation, reducing protein, lipids, DNA and mitochondrial damage and increasing antioxidant potential. Lycopene supplementation reduced DNA damage, up-regulated mitochondrial gene expression and reduced mitochondrial oxidation. Foot-and-mouth disease (FMD) was significantly increased by 1.1 points (10.9%) with 4-weeks lycopene supplementation in adults with coronary vascular disease. Blood pressure was reduced with lycopene supplementation in individuals with stage 1 hypertension, who were otherwise healthy.

Lycopene impacts blood lipids, where a dose-dependent reduction in intracellular cholesterol was seen in human studies, and lycopene and tomato products decreased plasma total cholesterol, low-density lipoprotein (LDL) cholesterol and increased high-density lipoprotein (HDL) cholesterol in animal models. Lycopene supplementation reduced cholesterol and LDL in healthy postmenopausal women. Significant increase in HDL and decrease in total cholesterol (TC), LDL and triglyceride (TG) were observed in lycopene-supplemented rats, and a reduction in oxidized LDL in lycopene-supplemented humans and lycopene-supplemented rats.

Intima media thickness (IMT) is an established index of the structural change of an artery and IMT, especially that of the carotid, is associated with the presence of cardiovascular risk factors. Serum carotenoid and lycopene levels are inversely related with IMT, especially that of the carotid. Numerous animal models demonstrated a reduction in carotid intima-media thickness. The liver is the largest visceral organ in the abdominal cavity and largest gland in the body, weighting about 1.5 kg in a healthy adult. The liver plays a major role in metabolism, including the production of certain proteins, cholesterol and the conversion of excess glucose to glycogen, and is involved in over 500 vital functions such as drug detoxification, the production of bile and the synthesis of steroid hormones. Non-alcoholic fatty liver disease (NAFLD), the most common form of liver disease, refers to a group of conditions resulting in excess fat in the liver (hepatic steatosis) of people who drink little or no alcohol and involves the development of insulin resistance, lipid peroxidation, oxidative stress and inflammation. Global and US prevalence of NAFLD are both estimated at 24%. As potent antioxidants and anti-inflammatory agents, carotenoids can play a role in protecting the liver against oxidative stress, insulin resistance and inflammation. In a prospective study of Chinese adults aged 40-75-years, higher serum carotenoid concentrations were positively associated with NAFLD improvements, specifically in lowering serum RBP4, triglycerides, homeostasis model assessment-insulin resistance (HOMA-IR), and body mass index (BMI). Lycopene is one of the most studied carotenoids regarding NAFLD due to multiple mechanisms beyond its antioxidant capacity, such as regulation of gene expression and gap junctions, antiproliferative capacity, lipid peroxidation and immune and hormonal modulation.

| Wang J et al. 125   | 30 male C57Bl/6j mice | 0.03% lycopene w/w mixed into normal chow, 5 weeks | ↓ LPS-induced insulin resistance and mitochondrial dysfunction ↓ Neuro and hepatic inflammation ↓ Circulating insulin and proinflammatory mediators (TNF-α, IL-1β, IL-6, IL-10) |
| Yim Y et al. 79     | T2DM Sprague Dawley rats | 10, 20 mg lycopene, 10 weeks | ↓ MDA and ↑ SOD and GSH-Px in pancreatic tissue |
Carotenoids accumulate in the skin and can protect against UV-generated ROS. Multiple factors impact their skin concentration. Dietary supplementation can increase skin carotenoid concentration, and oxidative stress, for example from cigarette smoking or exposure to UV-rays, can decrease their concentration. Lycopene skin and plasma concentration was shown to be comparable or higher than that of β-carotene. Lycopene supplementation increases both skin and plasma lycopene concentration, and a correlation between lycopene skin and plasma concentration has been demonstrated. Ribaya-Mercado et al found Lycopene to be the most quickly depleted antioxidant in skin upon solar radiation exposure, and suggest lycopene plays a role in mitigating photo-oxidative damage in tissues through protection against UV-radiation. A significant correlation between skin roughness and lycopene skin concentration has been seen.

Consumption of lycopene and lycopene-rich products protects the skin against sunburn by increasing the basal defense against UV light-mediated damage. Studies have demonstrated supplementation with lycopene or lycopene-rich products, or lycopene mixed with other carotenoids or antioxidants reduce UV-induced erythema and increase minimal erythema dose (MED). Forty percent (40%) reduction in erythema resulted after 10 weeks daily consumption of 40 g tomato paste, equivalent to 16 mg lycopene. Twelve weeks daily supplementation of 8 mg each of lycopene, lutein and β-carotene ameliorates UV-induced erythema. An increase in MED and reduction in UV-induced erythema was observed after 7-weeks daily supplementation of an antioxidant complex including lycopene, β-carotene, α-tocopherol and selenium. Lycopene-enriched tomato extract suppressed skin tumorigenesis in BALB/c mice, inhibited cell proliferation, decreased expression of angiogenic genes and increased expression of transmembrane proteins.

Lycopene protects the skin against photoaging by its antioxidative capacity, anti-inflammatory effects, impact on gene expression, and protection against lipid peroxidation.

|                          |                          |                         | ↑ in sebum lycopene concentration during first 2 weeks of supplementation |

Skin Health
The skin is the largest organ of the body, accounting for approximately 15% of total body weight. The skin protects against external physical, chemical, and biological assailants, prevents excess water loss from the body, and regulates body temperature. Carotenoids protect the skin against photoaging by their antioxidative properties. Carotenoids are also involved in the regulation of gene expression and the prevention of skin aging. The skin protects against ultraviolet (UV) radiation, and carotenoids play a role in mitigating photo-oxidative damage in tissues. Consumption of lycopene and lycopene-rich products may protect the skin against sunburn by increasing the basal defense against UV light-mediated damage.

Table 4 presents recent studies on the effects of lycopene and skin.

| Pessev I et al. 149      | 120 healthy human adults; subgroup for supplementation 15 healthy human adults | 7 mg daily, 4 weeks | Significant ↑ in desquamated corneocytes lycopene concentration during whole supplementation period |
|                          |                          |                         | ↑ in sebum lycopene concentration during first 2 weeks of supplementation |

Carotenoids accumulate in the skin and can protect against UV-generated ROS. Multiple factors impact their skin concentration. Dietary supplementation can increase skin carotenoid concentration, and oxidative stress, for example from cigarette smoking or exposure to UV-rays, can decrease their concentration. Lycopene skin and plasma concentration was shown to be comparable or higher than that of β-carotene. Lycopene supplementation increases both skin and plasma lycopene concentration, and a correlation between lycopene skin and plasma concentration has been demonstrated.

Ribaya-Mercado et al found Lycopene to be the most quickly depleted antioxidant in skin upon solar radiation exposure, and suggest lycopene plays a role in mitigating photo-oxidative damage in tissues through protection against UV-radiation.

A significant correlation between skin roughness and lycopene skin concentration has been seen.

Consumption of lycopene and lycopene-rich products protects the skin against sunburn by increasing the basal defense against UV light-mediated damage. Studies have demonstrated supplementation with lycopene or lycopene-rich products, or lycopene mixed with other carotenoids or antioxidants reduce UV-induced erythema and increase minimal erythema dose (MED). Forty percent (40%) reduction in erythema resulted after 10 weeks daily consumption of 40 g tomato paste, equivalent to 16 mg lycopene. Twelve weeks daily supplementation of 8 mg each of lycopene, lutein and β-carotene ameliorates UV-induced erythema.

An increase in MED and reduction in UV-induced erythema was observed after 7-weeks daily supplementation of an antioxidant complex including lycopene, β-carotene, α-tocopherol and selenium. Lycopene-enriched tomato extract suppressed skin tumorigenesis in BALB/c mice, inhibited cell proliferation, decreased expression of angiogenic genes and increased expression of transmembrane proteins.

Lycopene protects the skin against photoaging by its antioxidative capacity, anti-inflammatory effects, impact on gene expression, and protection against lipid peroxidation.

Table 4. Recent Studies - Lycopene and Skin

| Authors                  | Population               | Lycopene Dose, Duration | Results                                                                 |
|--------------------------|--------------------------|-------------------------|------------------------------------------------------------------------|
| Grether-Beck S et al. 122| 65 healthy human adults  | 10 mg daily, 12 weeks   | Inhibited mRNA expression of HO-1, MMP-1 and ICAM-1                   |
| Groten K et al. 139      | 149 healthy human adults | 15 mg lycopene, 5.8 mg phytocarotenoids, 0.8 mg beta-carotene, 5.6 mg tocopherols from tomato extract and 4 mg carnosic acid from rosemary or placebo | Protected against UVB-induced erythema
|                          |                          |                         | Significantly ↑ UVB-induced IL6 and TNFs                               |
| Koul A et al. 149        | 60 male Balb/c mice      | 5 mg/kg bw lycopene-enriched tomato extract | ↑ tumor incidence, size, number, burden and volume
|                          |                          |                         | ↓ mRNA and protein expression of VEGF, Ang-2, bFGF                      |
|                          |                          |                         | ↑ Cx-32, Cx-43                                                         |
| Pessev I et al. 149      | 32 healthy human adults  | 7 mg daily, 4 weeks     | Significant ↑ serum concentration 2.6 & 3.4x over control after 2 & 4 wks, respectively
|                          |                          |                         | Stepwise ↑ in IF staining of skin corneocytes and sebum                |
| Pessev I et al. 149      | 120 healthy human adults; subgroup for supplementation 15 healthy human adults | 7 mg daily, 4 weeks | Significant ↑ in desquamated corneocytes lycopene concentration during whole supplementation period |
|                          |                          |                         | ↑ in sebum lycopene concentration during first 2 weeks of supplementation |

Skin Health
The skin is the largest organ of the body, accounting for approximately 15% of total body weight. The skin protects against external physical, chemical, and biological assailants, prevents excess water loss from the body, and regulates body temperature.
Supplementation with lycopene-rich TNC and lutein-containing capsules resulted in a significant reduction of UV-induced mRNA expression of HO-1, MMP-1 and ICAM-1. Lycopene, β-carotene, α-tocopherol, and selenium supplementation showed a reduction of UV-induced p53 expression, sun burn cells (SBCs) and lipoperoxide levels. Lycopene from tomato extract protected against upregulation of proinflammatory cytokines. Supplementation of a lycopene, β-carotene and antioxidant combination inhibited the expression of matrix metalloproteinase (Table 4).

CONCLUSION

Lycopene, one of the six most predominant carotenoids found in the human diet and plasma, is the most potent singlet oxygen quenching carotenoid and a strong anti-inflammatory agent. Aging and major health problems today deal with the accumulation of ROS, including inflammation and irregular lipid metabolism. Due to its antioxidative and anti-inflammatory effects, and other mechanisms demonstrated in the research, for example lipid metabolism and cellular communication and differentiation, lycopene can play a protective role in aging and be a key component in strategies to tackle lifestyle metabolic and chronic health issues.
