Abstract
Platinum (Pt) is a conventional material for counter electrodes of dye-sensitized solar cells (DSSCs) due to its excellent electrocatalytic activity in the redox process. However, the high cost of Pt motivates researchers to search for composite materials of Pt to reduce its consumption. This study is aimed to reduce Pt usage by incorporating reduced graphene oxide (rGO) with Pt of different ratios in counter electrode thin films and to determine the optimum ratio with the highest efficiency. A DSSC-based platinum/rGO (Pt/rGO) counter electrode composite was fabricated using doctor-blade method. X-ray diffraction analysis was performed to examine the crystallite structure of the Pt/rGO thin film. The optimum ratio was found to be 70:30 of Pt:rGO, with current–voltage characterization showing an efficiency of 5.5%, open-circuit voltage of 0.739 V, current density of 12.5 mA/cm², and fill factor of 59.24%.

Keywords: counter electrode, dye-sensitized solar cell, graphene, platinum, thin film

Introduction
Over the past decade, green and renewable energy sources have been explored and used [1] to reduce CO₂ emissions [1-3]. Several types of renewable energy include hydro, wind, and solar or photovoltaic (PV). Among these sources, PV is the third most valued energy source that leads to the intense development of PV cell technology in recent years [1]. The sun is the best source of energy among the renewable or non-renewable energy because it provides 174,000 TW per year to the earth [4]. In other words, the energy from the sun should be utilized optimally. Ongoing
intense research is currently still being conducted for PV energy sources. Currently, PV energy sources have three generations of solar cell. The first generation is the silicon solar cell, in which the power conversion efficiency achieved 25% [5]. Presently, the silicon solar cell has dominated the market, but the high production cost has limited the spread of cell application. The second generation is the compound solar cell, in which gallium arsenide reached 28% [6] efficiency and cadmium telluride attained 20% [6, 7]. However, similarly the second generation also bears a high cost of production, which leads to the third generation. The third generation consists of dye-sensitized solar cells (DSSCs), organic solar cell, and quantum dots solar cells [8]. Third generation cells have lower cost production than conventional solar cell and have green technology that minimizes the environmental effect.

DSSC is one of the third generations of PV devices that gained the attention from most researchers. DSSC has several important parts that make up the cells; these parts include the titanium dioxide (TiO₂) photoanode, which helps excite the electron to the covalent bond; platinum (Pt) counter electrode, which acts as a catalyst in redox process; ruthenium dye (N719), which acts as a sensitizer that absorbs photon from light; and iodide electrolyte, which helps transfer the electron between two electrodes and also works in the redox process [9, 10]. Pt is a catalyst material that helps in reducing the triiodide ions into an iodide ion at counter electrode and electrolyte interface [11]. A faster rate of reducing the triiodide ions results in fast electron charge transfer. However, Pt is corrosive toward iodide electrolyte and is commercially expensive [12]. Therefore, replacing Pt with other materials or reducing Pt consumption using Pt composite materials is crucial. In addition, it is necessary to find the material that has a high electrocatalytic activity compared with Pt.

Recently, graphene has attracted much attention as a counter electrode material because of its electrical properties, corrosive resistance, low cost, and abundance [13]. The rGO structure is a three-dimensional network and has an oxygen-containing functional group that contributes to the electrocatalytic activity of rGO counter electrode [14]. Graphene is considered as a promising composite material with Pt. Hence, several ratios of composite Pt/rGO thin films were prepared in the starting ratio of the weight of the Pt to rGO 99:1 as the first ratio. The ratio of the rGO and the Pt will continuously increase and decrease, respectively. This paper focuses on determining the optimum ratio of rGO that can be incorporated into the Pt-based DSSC while reducing the use of Pt to achieve higher efficiency than Pt-based DSSC.

**Materials and Methods**

**Materials**

TiO₂ (WER2-0, Solaronix) was used as photoanode thin film, platinum paste PT-1 was purchased from Dyesol-Australia, and rGO-B026 purchased from graphenea were used as the counter electrode thin films. The N719 ruthenium dye sensitizer purchased from Dyesol were diluted with ethanol to form 0.3 mM solution mixture. Iodide electrolyte (Iodolyte, AN-50) performed as an electrolyte. An 8 Ω cm⁻² FTO glass substrate (FTO Tec 8, Dyesol) and 15 Ω cm⁻² FTO thin film (FTO Tec 15, Dyesol) will function as a counter electrode and photoanode glass substrate, respectively. Surlyn (Meltonix) is an adhesive material that helps photoanode and counter electrode glass substrate to attach together.

**Preparation of the counter electrode thin films**

Pt/rGO CE thin films were prepared with commercially available Pt paste and rGO powder. The Pt/rGO thin films were prepared as the ratio of the weight of Pt to rGO are 99:1, 95:5, 90:10, 85:15, 80:20, 75:25, 70:30, and 65:35. The Pt paste and rGO powder were ultrasonicated by the ultrasonic bath for approximately 15 minutes to create homogeneous composite mixture. Then, the mixture was stirred for another 15 minutes using the magnetic stirring bar and pasted onto the glass substrate of the 1.5 cm × 2 cm, 8 Ω cm⁻² fluorine-doped tin oxide (FTO) using doctor-blade method. Pt/rGO CE thin films were annealed for 30 minutes at 450 °C.

**Fabrication of the DSSC**

TiO₂ photoanode thin films were also prepared using the doctor-blade method, and the thin films were then immersed in the N719 ruthenium dye for 16 h with an active area of 0.25 cm². The photoanode and counter electrode were attached together by using a warm press machine to melt the Surlyn placed between the two electrodes. The active area part was injected with iodide electrolyte through the aperture between the electrodes. Then, the aperture was sealed to complete the fabrication of DSSC.
Results and Discussion

X-ray diffraction analysis

The X-ray diffraction (XRD) pattern of Pt, composite Pt/rGO of different ratio, and rGO are illustrated in Figure 1. Pt has been observed to have a prominent peak at (111) plane attributed to 39.8° with JCPDS of 03-065-2868. The Pt peak decrease until ratio 90:10 and rise slightly at ratio 85:15 before decreasing again at ratio 80:20 as the weight ratio of rGO increases. rGO has a weak intensity, shown in J of Figure 1, where the hkl plane of (006) attribute to 26.6° with JCPDS of 00-026-1076. SnO$_2$ diffraction angle is 26.5°, which is close to the rGO at (110) plane. The presence of Pt has concealed the rGO peak when Pt is mixed with the rGO. This process resulted in no visible rGO peak for the XRD pattern of Pt/rGO CE thin film. Thus, Pt is more crystallized than rGO. The crystallite size for each CE thin film can be calculated using Debye–Scherrer equation as in (1) [15],

$$D = \frac{0.9\lambda}{\beta \cos \theta}$$

(1)

where $D$ is the crystallite size, $\lambda$ is the wavelength, $\beta$ is the full width at the half maximum in radians, and $\theta$ is the diffraction angle. The crystallite sizes of the CE have been calculated, and the plotted graph is depicted in Figure 2. From the graph, the crystallite size increase until ratio of Pt:rGO is 95:5 and the crystallite size began to fluctuate at the range 29 – 36 nm approximately until ratio of Pt:rGO is 75:25. The crystallite size continues to decrease again at the ratio of Pt:rGO 70:30 although the amount of rGO keeps increasing. The larger the size of crystallite leads to high surface roughness of the thin films. The higher surface roughness of the thin film contributes to large surface area that instigates the high conductivity of the counter electrode thin film. Thus, from Figure 2 we can determine that counter thin film of Pt/rGO with ratio 80:20 has better conductivity among other due to large size of crystallite.

![Figure 1. XRD of CE thin film. A is Pt. B–I is Pt:rGO with ratio 99:1, 95:5, 90:10, 85:15, 80:20, 75:25, 70:30, and 65:35. J is rGO](image)
Field emission scanning electron microscopy analysis

The field emission scanning electron microscopy (FESEM) images of the thin films are used to study the morphology of the composite Pt:rGO counter electrode thin films (Figure 3). Pt is observed to have nano-like particle that spread homogeneously on the FTO glass substrate, and rGO is a nanosheet that has randomly aggregated. The three ratios of composite Pt:rGO thin films of the counter electrode are displayed in Figure 3. The Pt:rGO of ratio 99:1 is the first ratio, where we can observe that Pt nanoparticles are more than the rGO nanosheets. The Pt nanoparticles decrease with the increase of the rGO, and the Pt:rGO of ratio 70:30 is the optimum ratio with higher efficiency. In ratio 70:30, the Pt nanoparticles were well blended in the rGO nanosheets. When the rGO increases, the Pt nanoparticle can no longer blend with the rGO nanosheets as presented in Figure 3. In ratio 65:35, we hardly observe the Pt nanoparticle and a small amount of rGO nanosheets attached to FTO glass substrate.
Current-voltage analysis

Figure 4 shows the current–voltage characterization for the DSSC with a different type of CE. The efficiency of the DSSC can be calculated by Martinson et al. [16] using equation 2:

$$\eta = \frac{V_{oc}J_{sc}FF}{P_{in}}$$

(2)

where $\eta$ is the efficiency of the device equals to the product of $V_{oc}$, $J_{sc}$, and FF divided by an $V_{oc}$ of 100 mW/cm$^2$ under AM 1.5 ($P_{in}$). The $I$–$V$ curve for rGO is the lowest with $J_{sc}$ of 8.40 mA/cm$^2$ and an $V_{oc}$ of 0.62 V, resulting in poor efficiency of 1.97% as presented in Table 1. It can be seen that the conductivity of the thin film increase as the value of $J_{sc}$ increase following the increase of the amount of rGO. This is due to the rGO is more conductivity than Pt, the adding of the rGO improves the conductivity of the thin films. The $I$–$V$ curve of Pt/rGO-based DSSC of ratio 70:30 shows high $J_{sc}$ (12.50 mA/cm$^2$) with $V_{oc}$ of 0.74 V, resulting in high efficiency of 5.5 %, which is better than Pt-based DSSC. Table 1 summarizes all the $I$–$V$ curve parameter of DSSC. Therefore, the addition of the rGO in CE thin film increases the efficiency of the DSSC until the ratio of Pt:rGO of 70:30. The efficiency decreases when more rGO is added. Thus, 70:30 is the optimum ratio of rGO that can be incorporated with Pt as a CE material.
Table 1. $I$–$V$ characterization parameter of DSSC with Pt CE, various ratio of Pt:rGO, and rGO

| Counter electrode | $V_{oc}$ (V) | $J_{sc}$ (mA/cm$^2$) | $FF$ (%) | $\eta$ (%) |
|------------------|--------------|----------------------|----------|------------|
| rGO              | 0.62         | 8.40                 | 37.30    | 1.97       |
| Pt               | 0.80         | 8.43                 | 66.23    | 4.46       |
| Pt:rGO 99:1      | 0.74         | 9.73                 | 64.59    | 4.67       |
| Pt:rGO 95:5      | 0.75         | 10.00                | 64.07    | 4.8        |
| Pt:rGO 90:10     | 0.77         | 10.30                | 63.55    | 5.10       |
| Pt:rGO 85:15     | 0.77         | 10.20                | 61.80    | 4.80       |
| Pt:rGO 80:20     | 0.75         | 10.90                | 60.66    | 5.00       |
| Pt:rGO 75:25     | 0.74         | 11.40                | 61.80    | 5.20       |
| Pt:rGO 70:30     | 0.74         | 12.50                | 59.24    | 5.50       |
| Pt:rGO 65:35     | 0.73         | 10.10                | 63.18    | 4.70       |

Conclusion
The composite of Pt/rGO counter electrode thin films with different ratios were successfully prepared using doctor-blade method annealed at 450 °C for 30 min. The ratio of Pt/rGO that has been prepared were 99:1, 95:5, 90:10, 85:15, 80:20, 75:25, 70:30, and 65:35. The pattern of the increase and decrease of the efficiency of the DSSCs is observable after reaching the optimum ratio. Pt and rGO CE thin film are also prepared using the same technique as references. The Pt/rGO of ratio 70:30 shows the highest efficiency of 5.5% with the $J_{sc}$ value of 12.50 mA/cm$^2$, $V_{oc}$ value of 0.74 V, and FF is 59.24. The Pt counter electrode-based DSSC incorporated with rGO has higher efficiency at an optimum ratio of 70:30 in comparison with the Pt efficiency, which is 4.46%. The objective to reduce the use of Pt in the counter electrode of DSSC is achieved.
