Abstract

**AIM**

To assess risk factors of hospital admission for acute colonic diverticulitis.

**METHODS**

The study was conducted as part of the second wave of the population-based North Trondelag Health Study (HUNT2), performed in North Trondelag County, Norway, 1995 to 1997. The study consisted of 42570 participants (65.1% from HUNT2) who were followed up from 1998 to 2012. Of these, 22436 (52.7%) were females. The cases were defined as those 358 participants admitted with acute colonic diverticulitis during follow-up. The remaining participants were used as controls. Univariable and multivariable Cox regression analyses were used for each sex separately after multiple imputation to calculate HR.

**RESULTS**

Multivariable Cox regression analyses showed that increasing age increased the risk of admission for acute colonic diverticulitis: Comparing with ages < 50 years, females with age 50-70 years had HR = 3.42, P < 0.001 and age > 70 years, HR = 6.19, P < 0.001. In males the corresponding values were HR = 1.85, P = 0.004 and 2.56, P < 0.001. In patients with obesity (body mass index ≥ 30) the HR = 2.06, P < 0.001. In patients with obesity (body mass index ≥ 30) the HR = 2.06, P < 0.001. In patients with obesity (body mass index ≥ 30) the HR = 2.06, P < 0.001. In patients with obesity (body mass index ≥ 30) the HR = 2.06, P < 0.001. In females, present (HR = 2.11, P < 0.001) or previous (HR = 1.65, P = 0.007) cigarette smoking increased the risk of admission. In males, breathlessness (HR = 2.57, P < 0.001) and living in rural areas (HR = 1.74, P = 0.007) increased the risk. Level of education, physical activity, constipation and type of bread eaten showed no association with admission for acute colonic diverticulitis.

**CONCLUSION**

The risk of hospital admission for acute colonic diverticulitis increased with increasing age, in obese individuals, in ever cigarette smoking females and in males living in rural areas.

**Key words:** Acute colonic diverticulitis; North Trondelag Health Study; Risk factors; Multivariable Cox regression analysis; Multiple imputation

**Core tip:** We sought to determine what health related factors were together associated with later admission for acute colonic diverticulitis. The factors were derived from the North Trondelag Health Study (HUNT2) in Norway, the HUNT2 study, performed during 1995-1997. The study had 42570 participants who used Levanger Hospital as their primary hospital. They were observed until 2012. Following HUNT2, the participants contributed 611492 person-years of follow-up. In all, 358 cases had been admitted with acute colonic diverticulitis. In a multivariable analysis, increasing age and increasing Body Mass Index were associated with increased risk of admission for acute colonic diverticulitis in both gender. In females, cigarette smoking likewise increased the risk of admission. In males, breathlessness, a HUNT variable associated with Chronic Obstructive Pulmonary Disease, increased the risk of admission. On the other hand, physical activity, constipation and type of bread eaten showed no association with admission for acute colonic diverticulitis.

Risk factors of admission for acute colonic diverticulitis in a population-based cohort study: The North Trondelag Health Study, Norway. *World J Gastroenterol* 2016; 22(48): 10663-10672 Available from: URL: http://www.wjgnet.com/1007-9327/full/v22/i48/10663.htm DOI: http://dx.doi.org/10.3748/wjg.v22.i48.10663

**INTRODUCTION**

Diverticular disease of the colon is highly prevalent in Western populations and adds to the already rising expenditures in healthcare systems[1]. The prevalence of diverticular disease is age dependent and increases from 5% in the age group 30-39 years to 60% among those older than 80 years of age[2].

Acute diverticulitis is the most common complication of colonic diverticulosis[3], with increasing incidence and admission rates in recent years[4,5]. Acute diverticulitis may also recur in 9% to 23% of patients[6].

The heritability of diverticular disease has been estimated at 40% in a large Swedish twin study[7], and a number of lifestyle related risk factors have been attributed to acute colonic diverticulitis. Obesity, reduced physical activity, tobacco smoking and reduced dietary fiber intake have all been associated with increased risk of acute colonic diverticulitis, but few studies have been able to assess all these factors together[8-12].

The aim of the present study was to assess risk factors of hospital admission for acute colonic diverticulitis in a prospective population-based cohort study.
MATERIALS AND METHODS

Study population
During 1995 to 1997, all residents in North Trondelag County, Norway, aged 20 years and older, were invited to participate in the second wave of the North Trondelag Health Study (HUNT2), a survey consisting of written questionnaires on health related topics, physical examinations and blood sampling[13]. In the present study, the population of the ten municipalities who used Levanger Hospital as the primary hospital was included, representing 73% of the population in North Trondelag County. The great majority are ethnic whites.

During 2012 and 2013 we retrospectively searched for all patients who had been admitted to Levanger Hospital following HUNT2, from 1998 to 2012, with the diagnosis acute colonic diverticulitis. The population of North Trondelag is served by two hospitals, Levanger Hospital is the largest and serving 10 municipalities. All treatment is given free of charge for the population. The patients were identified in the hospital patient administrative system, using the discharge codes for colonic diverticular disease in international classification of diseases ICD-9 and ICD-10. All the records were reviewed to ensure a higher probability of a correct diagnosis of acute colonic diverticulitis. All 358 patients who had been admitted with acute colonic diverticulitis and had participated in HUNT2 were included in the present study as cases, and the remaining HUNT2 participants from the same ten municipalities were used as controls. Figure 1 shows a flowchart of participants and patient inclusions.

A computed tomography (CT) scan had been performed during the hospital stay in 161 patients (45%) and later in 52 (14.5%) additional patients during outpatient follow-up. Colonoscopy had been performed in 139 (38.8%) patients. During the early years of the study (mainly between 1998 and 2006), a barium enema had been done in 120 (33.5%) patients to diagnose diverticula in the colon. One or more of these examinations had been performed in 331 patients (92.5%).

Table 1 Percentage missing values in different variables

| Variable                  | Females | Males |
|---------------------------|---------|-------|
| Hard physical activity    | 39      | 28    |
| Cigarette smoking         | 7       | 5     |
| Breathlessness            | 16      | 10    |
| Constipation              | 12      | 9     |
| Type of bread             | 13      | 16    |
| Highest educational level | 6       | 5     |

Ethical approval
The participants in HUNT2 gave written informed consent for medical research, including future linkage to patient records at the hospitals. The present study is approved by the Regional Committee for Health and Research Ethics (2011/1782/REK midt).

RESULTS
In HUNT2, 65372 persons attended (69.5% response rate). Of these, 42570 persons had Levanger Hospital as their primary hospital and were included in the present study. Following HUNT2, the participants contributed 611492 person-years of follow-up, and 358 cases were admitted with acute colonic diverticulitis (Figure 1). The remaining HUNT2 participants belonging to Levanger Hospital were used as controls, excluding the 129 persons who had been admitted with acute colonic diverticulitis during 1988 and 1997 (preceding HUNT2).

Baseline characteristics
In the included cohort, 22436 (52.7%) were females. The mean age at baseline was 50.0 (SD 17.2) and 49.5 (SD 16.7) years for females and males, respectively. During follow-up, 358 participants were admitted to Levanger Hospital with acute colonic diverticulitis, 233 (65.1%) were females, and the mean age at admission was 69.3 (SD 13.2) and 63.9 (SD 14.1) years for females and males, respectively. Among the patients who had been admitted with acute colonic diverticulitis, but did not participate in HUNT2 (excluded from the present study), 54 (42%) were females, and the mean age at admission was 62.6 years (SD 16.0) for females, and 52.7 years (SD 16.6) for males.

Mean time from participation in HUNT2 to admission for acute colonic diverticulitis was 9.48 (SD 4.5) and 9.16 (SD 4.4) years for females and males, respectively.

Table 2 shows the sex-specific distribution of baseline characteristics of cases and controls. In both sexes, the age and BMI were higher and frequency of physical activity was lower among cases than controls. In females, more cases smoked cigarettes daily than controls. In both sexes, cases were more affected with breathlessness and constipation than controls. In both sexes, coarse type of bread was eaten more frequently in cases than controls. In both sexes, cases had lower educational level than controls. Among males, cases lived more often in a rural area than controls.
Risk factors for admission for acute colonic diverticulitis

Tables 3 and 4 shows the results of univariable and multivariable Cox regression analyses for each sex separately after the multiple imputation. In the multivariable analysis, increasing age was associated with increased risk of admission for acute colonic diverticulitis in both sexes (HR = 3.42, 95%CI: 2.40-4.86, P < 0.001 for ages 50-70 years and HR = 6.19, 95%CI: 4.02-9.54, P < 0.001 for ages > 70 years in females). In males, the corresponding values were HR = 1.85, 95% CI: 1.22 to 7.80, P = 0.004 and 2.56, 95%CI: 1.45-4.52, P < 0.001. Obesity was associated with increased risk of admission for acute colonic diverticulitis in both sexes (HR = 2.06, 95%CI: 1.46-2.91, P < 0.001 in females and HR = 2.58, 95%CI: 1.53-4.34, P < 0.001 in males). In females, both present and former daily cigarette smoking was associated with increased risk of admission for acute colonic diverticulitis (HR = 1.65, 95%CI: 1.15-2.36, P = 0.007 for former smokers). In males, an increased risk of admission for acute colonic diverticulitis was observed in persons who reported slight problem with breathlessness during the last 12 mo (HR = 2.57, 95%CI: 1.55-4.28, P < 0.001) and in persons living in a rural area (HR = 1.74, 95%CI: 1.17-2.58, P = 0.007).

Level of education, hard physical activity, constipation and type of bread eaten showed no association with the risk of admission for acute colonic diverticulitis.

Table 2 Baseline characteristics of the study population n (%) 

| Characteristic | Acute colonic diverticulitis 1998-2012 | Females | Yes | No | Males | Yes | No |
|---------------|----------------------------------------|---------|-----|----|-------|-----|----|

| Rural         | 3978 (99.1)                           | 38 (0.9)  | 3584 (99.1) | 34 (0.9)  |

Data given as n (%) unless otherwise stated.
We also carried out these analyses separately for each of the three age groups. Results were substantially the same (data not shown).

In another analysis, we excluded the variable breathlessness, and there were only insignificant changes in the HRs for all of the remaining variables.

**DISCUSSION**

**Main findings**

The main finding of this prospective population-based cohort study was that obese individuals had twice the risk of admission for acute colonic diverticulitis compared to normal weight individuals. This association was found in both females and males. Moreover, previous and present daily cigarette smoking also increased the risk of admission for acute colonic diverticulitis in females. There was no association between hard physical activity, constipation or eating bread with fine or coarse grains and risk of admission for acute colonic diverticulitis.

**Relation to other reports**

The present study demonstrated an increased risk of admission for acute colonic diverticulitis by increasing age in both females and males. This is consistent with findings reported by other studies. There was an increased risk of admission for acute colonic diverticulitis in obese persons (BMI $\geq 30$). This is in agreement with other population-based studies. In two prospective cohort studies of males, the risk of acute colonic diverticulitis was 1.6 and 3.2 times higher among overweight individuals (BMI 25-29.9) and 1.8 and 4.4 times higher among obese individuals (BMI $\geq 30$), compared with those of normal weight (BMI 18.5-4.9). In a prospective cohort study of females, the risk was 1.3 times higher for overweight and obese individuals. A weakness with these studies was the sex-specific nature of the cohorts.

Previous studies found that physical activity, in general, decreased the risk of acute colonic diverticulitis. However, the present study found no association between hard physical activity for at least

BMI: Body mass index.
one hour per week and admission for the disease after adjustments. Cigarette smoking has been associated with increased severity of acute colonic diverticulitis. In the present study, daily smoking increased the risk of admission for the disease by 2.2-fold in females. Previous studies found that smoking increased the risk of acute colonic diverticulitis by 25%-60% in both sexes and increased the risk of complicated diverticulitis by 2.7 to 3.6-fold. However, drawbacks of these studies were small number of cases, sex-specific cohorts or lack of adjustments for dietary and other lifestyle factors like physical activity.

A previous long term study from this area of patients admitted with acute colonic diverticulitis, revealed an increased long term mortality by chronic obstructive pulmonary disease (COPD) of 10% (95%CI: 6.0-16) in. In comparison, COPD was the cause of death in 4.2% (95%CI: 4.0-4.4) in the total population from the same area. This suggested a link between COPD and acute colonic diverticulitis, which was also found in another study. In the present study, we wanted to elucidate the association between COPD and diverticulitis in another way. Duration of breathlessness was chosen as a proxy variable for COPD from HUNT2. The results of the present study showed that shortness of breath was associated with increased risk of admission for the disease. Few studies have previously studied the possible relationship between COPD and diverticulitis, although one other study, found that complicated diverticulitis was associated with pulmonary symptoms and problems in 23% of the cases.

In the present study, constipation was not associated with increased risk of admission for acute colonic diverticulitis. Similar, a recent multicenter study found no association between constipation and left-sided colonic diverticulosis, while in another study, constipation was considered a symptom of, rather than a direct risk factor for, acute colonic diverticulitis.

High dietary fiber intake is traditionally thought to be associated with decreased risk of diverticular disease, although high quality evidence is lacking. In the present study, type of bread, whether fine or coarse, had no effect on the risk of admission for acute colonic diverticulitis. This is consistent with other studies, which found no association between cereals and acute colonic diverticulitis.

In the present study, males living in rural areas

### Table 4 Multivariable Cox regression analysis of risk factors relating to admission for acute diverticulitis, after multiple imputation for missing values

had 80% increased risk of admission for acute colonic diverticulitis. In two previous studies, the risk of acute colonic diverticulitis was slightly elevated in both sexes living in rural areas[16,34].

**Biological mechanisms**

Aging showed increased risk of admission for acute colonic diverticulitis. Colonic diverticulosis can be considered a degenerative disease in which increasing age leads to weakness of supporting connective tissue and subsequent increase in intraluminal pressure and later increased risk of colonic diverticulitis. However, the exact mechanism of increased risk of diverticulitis in humans with aging is still unclear[35].

Obesity is shown to be a risk factor for diverticular disease and its complications[8,11,19,35]. One likely mechanism for development of acute colonic diverticulitis is that increased fat deposition in the mesentery act pro-inflammatory with activation of macrophages within the adipose tissue and subsequent increase in TNF-α. Translocation of luminal bacteria from the intestine to the systemic circulation due to impaired barrier function may also play a role in this pathogenesis[35].

Cigarette smoking causes changes in the colonic wall structure in patients with diverticular disease that are similar to changes found in blood vessels caused by smoking in other organs. In addition, smoking is thought to affect colonic motility and intraluminal pressure[36].

There is a possible coexistence between COPD and acute colonic diverticulitis. While smoking is a known risk factor for both diseases, it is unclear whether COPD is a risk factor or comorbidity in this context. Both inflammatory bowel disease and COPD share many similarities in inflammatory pathogenesis[37], but the mechanism behind the association between breathlessness and risk of acute colonic diverticulitis is poorly understood.

**Strengths and weaknesses**

This study has a population-based design with a large sample size and high participation rate. This diminishes selection bias, strengthens the study power, reduces the risk of chance findings and facilitates subgroup analyses. The objective and uniform measurement of height and weight by qualified personnel minimized residual confounding, as there are always unknown confounders that are unaccounted for in such studies. Therefore, the study results may not be directly generalizable to a younger population. Some subjective variables that we used in the analysis, like symptom of constipation and breathlessness, educational level and living area, which is seldom done in analyses of acute colonic diverticulitis. We used multiple imputation to account for missing data with the resulting more accurate HRs and more precise CIs and significance tests.

Many patients with acute colonic diverticulitis have vague symptoms, does not seek the doctor, and recover without antibiotics. Only part of all patients with this disease will be admitted to hospital. We are not aware of any change in admission policy for acute colonic diverticulitis during the study period. In addition to using the ICD-codes set by the doctor in charge at discharge, every hospital record was reviewed to ensure a higher probability of a correct diagnosis and prevent misclassifications[41]. Still, the diagnosis of acute colonic diverticulitis may have been incorrect in a minority of patients with known diverticulosis, who presented with pain in the lower abdomen, fever and an elevated CRP without a CT scan.

CT scan is considered to be gold standard for the diagnosis of acute colonic diverticulitis. During the earlier years of this study, CT scan was used more infrequently. Even with the nowadays widespread availability of CT scans in many countries, we think it would be unadvisable due to radiation hazard, to perform CT scans in every patient with suspected uncomplicated, acute colonic diverticulitis.

Another limitation of the study is the 30% of non-participants in HUNT2. Non-participants, who were later admitted with acute colonic diverticulitis, were younger than participants in HUNT2: 7 and 9 years younger for females and males, respectively. Therefore, the study results may not be directly generalizable to a younger population. Some subjective variables that we used in the analysis, like symptom of breathlessness and type of bread eaten, could have led to information bias due to their questionnaires’ nature. Another limitation is possible biased estimates due to residual confounding, as there are always unknown confounders that are unaccounted for in such studies.

The results of the present study apply to patients with colonic diverticulitis that was severe enough to require admission to hospital. The conclusions cannot be transformed without reservations to patients with diverticulitis not admitted to hospital.

In conclusion, this large prospective population-based cohort study showed that increasing age was associated with increased risk of admission for acute colonic diverticulitis in both sexes. Obese individuals had twice the risk of admission for acute colonic diverticulitis compared to those with normal weight. Previous or present cigarette smoking increased the risk of admission for acute colonic diverticulitis in females. There was no association between constipation or eating bread with fine or coarse grains and admission for acute colonic diverticulitis.
