AN OBSTRUCTION BUNDLE RELATING GROMOV-WITTEN INVARIANTS OF CURVES AND KÄHLER SURFACES

By Junho Lee and Thomas H. Parker

Abstract. In a previous paper the authors defined symplectic “Local Gromov-Witten invariants” associated to spin curves and showed that the GW invariants of a Kähler surface $X$ with $p_g > 0$ are a sum of such local GW invariants. This paper describes how the local GW invariants arise from an obstruction bundle (in the sense of Taubes) over the space of stable maps into curves. Together with the results of our earlier paper, this reduces the calculation of the GW invariants of elliptic and general-type complex surfaces to computations in the GW theory of curves with additional classes: the Euler classes of the (real) obstruction bundles.

On a compact Kähler surface $X$, a holomorphic 2-form $\alpha$ is a section of the canonical bundle whose zero locus is a canonical divisor $D$. Several years ago, the first author observed (see [Lee1]) that each such 2-form $\alpha$ naturally induces an almost complex structure $J_\alpha$ that satisfies a remarkable property:

**Image Localization Property.** If a $J_\alpha$-holomorphic map represents a non-trivial $(1,1)$ class, then its image lies in $D$.

After further perturbing to a generic $J$ near $J_\alpha$, the images of all $J$-holomorphic maps cluster in $\varepsilon$-neighborhoods of the components of the canonical divisor $D$. This implies that the Gromov-Witten invariant of $X$ is a sum

$$GW_{g,n}(X,A) = \sum_k GW_{g,n}^{\text{loc}}(D_k,d_k[D_k])$$

over the connected components $D_k$ of $D$ of “local GW invariants” that count the contribution of maps whose image lies near $D_k$.

When $D$ is smooth, the local invariants depend only on the normal bundle $N$ to $D \subset X$. By the adjunction formula, $N$ is a holomorphic square root of the canonical bundle $K_D$, that is, $N$ is a theta-characteristic of the curve $D$ and the pair $(D,N)$ is a spin curve. The total space $N_D$ of $N$ has a tautological holomorphic 2-form $\alpha$ whose zero locus is the zero section $D \subset N_D$. For perturbations of the corresponding $J_\alpha$, all $J$-holomorphic maps cluster around the zero section. These clusters define local GW invariants of the spin curve $(D,N)$ which, the authors
proved in [LP], depend only on the parity of \( N \) (i.e. on \( h^0(N) \mod 2 \)). Altogether, we have

\[
GW_{g,n}(X,A) = \sum_k (i_k)_* GW^{\text{loc}}_{g,n}(N_{D_k},d_k)
\]

where \((i_k)_*\) is the induced map from the inclusion \( D_k \subset X \). Thus the computation of the GW invariants of Kähler surfaces with \( p_g > 0 \) is reduced to the problem of calculating the local invariants of spin curves.

Recently, Kiem and Li [KL] defined the local invariants by algebraic geometry methods and proved the formulas for degree 1 and 2 local invariants conjectured by Maulik and Pandharipande [MP]. The first author [Lee2] reproved those formulas by adapting the symplectic sum formula of [IP2] to local GW invariants.

Because (0.1) applies to all GW invariants, not just those of the “embedded genus”, one cannot apply Seiberg-Witten theory. Nor can the local invariants be computed by the usual methods of algebraic geometry, such as localization and Grothendieck-Riemann-Roch, because the linearized \( J_\alpha \)-holomorphic map equation is not complex linear. In particular, when genus(\( D_k \)) > 0 the local invariants in (0.1) are not the same as the “local GW invariants” used to study Calabi-Yau 3-folds [BP] or the “twisted GW invariants” defined by Givental.

While the local invariants are defined in terms of the GW theory of the (complex) surface \( N_D \) one would like, as a step toward computation, to recast them in terms of the much better-understood GW theory of curves (cf. [OP]). This paper uses geometric analysis arguments to prove that the local GW invariants of a spin curve \((D,N)\) arise from a cycle in the space of stable maps into the curve \( D \). The cycle is defined by constructing an “obstruction bundle”. While the basic idea is clear and intuitive, the construction is difficult because of technical issues involving the construction of a complete space of maps.

The intuition goes like this. The tautological 2-form \( \alpha \) on \( N_D \) determines an almost complex structure \( J_\alpha \). By the Image Localization Property, the space of stable \( J_\alpha \)-holomorphic maps into \( N_D \) representing \( d[D] \) is the same as the space of degree \( d \) stable maps into \( D \):

\[
\overline{M}^{J_\alpha}_{g,n}(N_D,d[D]) = \overline{M}_{g,n}(D,d)
\]

Counting dimensions, one sees that the formal dimension of \( \overline{M}_{g,n}(D,d) \) is exactly twice the dimension of the virtual fundamental class that defines the local GW invariants of \( N_D \) (when \( n = 0 \)). The dimensions do not match because \( J_\alpha \) is not generic. Perturbing \( J_\alpha \) to a generic \( J \) effectively reduces the space of maps to a half-dimensional cycle in \( \overline{M}_{g,n}(D,d) \) that defines the local GW invariants of the spin curve \((D,N)\). To understand this reduction, we use another remarkable property of the \( J_\alpha \)-holomorphic maps:
Injectivity Property. The linearization of the map \( f \mapsto \overline{\partial} J^\alpha f \), when restricted to the normal bundle, is an elliptic operator \( L_f \) whose kernel vanishes for every \( J^\alpha \)-holomorphic map \( (\alpha \neq 0) \).

The injectivity property implies that the vector spaces coker \( L_f \) have constant dimension. The construction of Section 8 shows that these cokernels form a locally trivial real vector bundle

\[
\mathcal{Ob}
\]

(0.3)

\[
\overline{\mathcal{M}}_{g,n}(D,d)
\]

over the space (0.2) whose rank is the formal GW dimension for surface. This is an “obstruction’ bundle” in the sense of Taubes: the Implicit Function Theorem shows that the space of perturbed holomorphic maps is diffeomorphic to the subset of \( \overline{\mathcal{M}}_{g,n}(D,d) \) given by the zero set of a certain section of \( \mathcal{Ob} \). As always, we have the associated map

\[
\hat{ev} = st \times ev : \overline{\mathcal{M}}_{g,n}(D,d) \longrightarrow \overline{\mathcal{M}}_{g,n} \times D^n
\]

(0.4)

whose first factor is the stabilization map and whose second factor records the images of the marked points. In this context, the GW invariants of the curve \( D \) are defined as the image of the virtual fundamental class \([\overline{\mathcal{M}}_{g,n}(D,d)]_{\text{vir}}\) under \( \hat{ev} \). Our main result is that the local GW invariants are defined from these by capping with the Euler class of this obstruction bundle:

Main Theorem. There is an oriented real bundle \( \mathcal{Ob} \) over \( \overline{\mathcal{M}}_{g,n}(D,d) \) whose isomorphism class depends only on the parity of the spin curve \( (D,N) \). When genus \( (D) > 0 \)

\[
GW_{g,n}^{\text{loc}}(N_D,d) = \hat{ev}_*([\overline{\mathcal{M}}_{g,n}(D,d)]_{\text{vir}} \cap e(\mathcal{Ob}))
\]

(0.5)

where the virtual fundamental class \([\overline{\mathcal{M}}_{g,n}(D,d)]_{\text{vir}}\) defines the GW invariants of the curve \( D \).

This formula describes how the local invariants evaluate on elements of the cohomology of \( \overline{\mathcal{M}}_{g,n} \times D^n \). But in the context of this theorem, all descendant classes are pullbacks of classes in \( H^*(\overline{\mathcal{M}}_{g,n} \times D^n) \) (see Section 1). Thus the equality (0.5) applies to descendant classes.

This theorem is a step toward computing the GW invariants of minimal Kähler surfaces with \( p_g > 0 \). For non-minimal surfaces, one would also need a version of the Main Theorem for the local GW invariants of an exceptional curve: when \( N \) is the bundle \( \mathcal{O}(-1) \) over \( D = \mathbb{P}^1 \). This case is fundamentally different: it is simpler because the Image Localization and Injectivity Properties hold for the standard complex structure, but is more complicated because a lemma essential for the
analysis—Lemma 1.2 below—does not apply when \( D = \mathbb{P}^1 \). As a result, the right-hand side of (0.5) is well-defined and the associated GW invariants are computable [FP], but our analysis does not show the equality in (0.5). This \( D = \mathbb{P}^1 \) case will be analyzed elsewhere.

The main theorem would not be difficult to prove if \( \mathcal{O} \mathcal{b} \to \overline{\mathcal{M}}_{g,n}(D,d) \) were a smooth vector bundle over a manifold, or if one could perturb to the smooth situation while retaining the Image Localization and Injectivity properties. Unfortunately, there do not currently exist theorems or techniques for smoothing the compactified moduli space. As a result, the proof of the main theorem must address two significant technical issues: (i) the lack of information about the structure of the moduli space near its boundary, and (ii) the local triviality of the obstruction bundle.

To deal with issue (i), we first perturb the \( J_\alpha \)-holomorphic map equation in the manner of Ruan-Tian [RT2]. The resulting moduli space \( \overline{\mathcal{M}} = \overline{\mathcal{M}}_{g,n}(D,d) \) of \( (J,\nu) \)-holomorphic maps into \( D \) consists of a smooth top stratum \( \mathcal{M} \) and boundary strata of codimension at least two. We fix a small neighborhood \( U \) of the boundary and consider its complement \( \mathcal{M}_U = \mathcal{M} \setminus U \). Then, after smoothing and perturbing \( U \) if necessary, \( \mathcal{M}_U \) is a compact smooth oriented manifold with boundary, so defines a relative homology class in \( \text{Map} \). In Section 3 we prove that this “relative virtual fundamental class” defines the same Gromov-Witten invariants as other standard definitions, including the one used in algebraic geometry.

On the compact manifold \( \mathcal{M}_U \), the \( (J,\nu) \)-holomorphic map equation defines a section of the obstruction bundle, and the Euler class \( e(\mathcal{O} \mathcal{b}) \) is Poincaré dual to the zero set of any section that is transverse to zero. We achieve transversality by adding a second Ruan-Tian perturbation term. In Section 9 we prove a generalized Image Localization Theorem that shows that this second perturbation leaves \( \mathcal{M} \) unchanged. The main theorem is proved in Section 10 by showing that the zero set of a section defines a rational homology class that is equal to the local GW invariants by cobordism, and on the other hand is equal to the right-hand side of (0.5) by Poincaré duality for \( \mathcal{M}_U \).

The analysis aspects of the proof are aimed at issue (ii) above: proving that the obstruction bundle is locally trivial. The key difficulty is that the normal component of the linearization of the \( J_\alpha \)-holomorphic map equation at a map \( f \) is an operator of the form \( L_f = \overline{\partial} + A(df) \), and \( df \) is not pointwise bounded in the topology of the Gromov compactness theorem. Thus it is not clear whether \( L_f \) is continuous in \( f \) on the space of smooth maps—a fact we need in order to show that \( \mathcal{O} \mathcal{b} \), which is essentially \( \text{coker} \ L_f \), is locally trivial (in the literature, continuity is often implicitly assumed). For this purpose, we introduce a stronger topology on the space of maps in Section 2 and prove a strengthened version of the Gromov compactness theorem. Then in Section 4 we extend the operators \( L_f \) off the set of \( J_\alpha \)-holomorphic maps as a family of “modified linearizations”; these are equally natural, but are more easily estimated, than the actual linearizations. Sections 5–7
develop the needed analysis results to show that $L_f$ is continuous in $f$ as an operator on appropriate weighted Sobolev spaces. The key to this analysis is the Poincaré inequalities proved in Section 6, which lead to estimates for the weighted norms that are uniform even as the domain degenerates to a nodal curve. These results are used in Section 8 to define the obstruction bundle and prove that it is locally trivial.

For computations, one would like to express the obstruction bundle $Ob$ in terms of algebraic geometry. At the Kähler structure $J_0$ on $N_D$, $L_f$ is the $\bar{\partial}$-operator on the bundle $f^*N$, the fiber $Ob_f$ is $H^{0,1}(f^*N)$, and the Injectivity Property suggests that $h^0(f^*N) = 0$. This would imply that $Ob$ is the index bundle $\text{ind}\bar{\partial}$. However, when $D$ has genus $g > 1$ the Injectivity Property does not hold for $J_0$ and, as in Brill-Noether theory, $h^{0,1}(f^*N)$ can jump up at special maps. (Pandharipande and Maulik showed us a specific example where such a jump necessarily occurs in the moduli space, and a similar example appears in [KL].) Thus $Ob$ is not in general equal to the $\text{ind}\bar{\partial}$. We clarify this in Section 11 by showing how the linearization $f \mapsto L_f$ defines a map from $\overline{\mathcal{M}}$ to a space $\mathcal{F}$ of real Fredholm operators. There are natural classes $\kappa_i \in H^*(\mathcal{F})$, first defined by Koschorke, that give obstructions to the bundle $\text{ind}_\mathbb{R}L$ being an actual vector bundle rather than a virtual bundle. We prove that all Koschorke classes vanish for the family of maps defined by the moduli space (0.2), so $Ob = \text{ind}_\mathbb{R}L$ is an actual bundle over the moduli space. This gives a homotopy-theoretic characterization of the obstruction bundle.

Zinger [Z] independently obtained (0.5) following the approach of Fukaya-Ono [FO] and Li-Tian [LT2]. He also describes some interesting generalizations of our main theorem.

Acknowledgment. We thank the referee for many helpful comments.

1. $J_\alpha$-holomorphic maps with stabilized domains. We begin with a review of the setup for $J_\alpha$-holomorphic maps; for details see [Lee1, LP]. Fix a Kähler surface $X$ with complex structure $J$ and geometric genus $p_g > 0$. Then the real vector space

$$\mathcal{H} = \text{Re} \left( H^{2,0} \oplus H^{0,2} \right)$$

has dimension $2p_g > 0$. Using the Kähler metric compatible with $J$, each $\alpha \in \mathcal{H}$ defines an endomorphism $K_\alpha$ of $TX$ by the equation

$$\langle u, K_\alpha v \rangle = \alpha(u, v).$$

Each $K_\alpha$ is skew-adjoint, anti-commutes with $J$, and satisfies $K^2_\alpha = -|\alpha|^2 Id$. It follows that $JK_\alpha$ is skew-adjoint and $Id + JK_\alpha$ is invertible. Thus there is a family of almost complex structures

$$J_\alpha = (Id + JK_\alpha)^{-1} J(Id + JK_\alpha)$$
on $X$ parameterized by $\alpha \in \mathcal{H}$. Note that while $\alpha$ is holomorphic, the corresponding almost complex structure $J_\alpha$ need not be integrable, and indeed, usually isn’t integrable.

For each $\alpha \in \mathcal{H}$, we can consider the set of maps $f : C \to X$ from a connected complex curve with complex structure $j$ into $X$ that satisfy the $J_\alpha$-holomorphic map equation

$$\overline{\partial} J_\alpha f = 0 \quad (1.3)$$

where $\overline{\partial} J_\alpha f = \frac{1}{2}(df + J_\alpha df j)$. It was shown in [Lee1] that these are exactly the maps that satisfy the “perturbed $J$-holomorphic map equation”

$$\overline{\partial} J f - \nu_\alpha = 0 \quad (1.4)$$

where $\nu_\alpha = K_\alpha (\partial J f) j$ (even though $\overline{\partial} J_\alpha f$ is not equal to $\overline{\partial} J f - \nu_\alpha$ for arbitrary maps). In this paper, we fix $J$ and work with the $J_\alpha$-holomorphic map equation in the form (1.4) rather than (1.3).

Because any holomorphic map into a Kähler surface represents a $(1,1)$ class, we can restrict attention to maps representing $(1,1)$ classes: the GW invariants vanish for all other classes. In this context, the first author observed that the following remarkable fact.

**Lemma 1.1.** (Image Localization) If $f : C \to X$ is a $J_\alpha$-holomorphic map that represents a non-trivial $(1,1)$ class, then the image of $f$ lies in one connected component $D_k$ of the zero set of $\alpha$.

This fact leads to the general formula (0.1) expressing the GW invariant as a sum of local invariants associated with the components of the divisor of $\alpha$. When such a divisor $D$ is smooth with multiplicity one, the square of its holomorphic normal bundle $N$ is the canonical bundle $K_D$, so $(N,D)$ is a spin curve. In this case, it was shown in [LP] that the local GW invariants depend only on the genus and parity of the spin curve $(D,N)$ (the parity is $h^0(N) \mod 2$).

Now consider a genus $h$ spin curve $(D,N)$, that is, a curve $D$ with genus $h$ and a holomorphic line bundle $N$ on $D$ with $N^2 = K_D$. The total space $N_D$ of $N$ has a complex structure $J$ that makes the projection $\pi : N_D \to D$ holomorphic. We then have an exact sequence

$$0 \to \pi^* N \to TN_D \to \pi^* TD \to 0 \quad (1.5)$$

and hence the canonical bundle of $N_D$ is $\pi^*(N^* \otimes K_D) = \pi^* N$. The tautological section of $\pi^* N$ is thus a holomorphic 2-form $\alpha$ on $N$ that vanishes transversally along the zero section $D \subset N_D$. This 2-form $\alpha$ induces an almost complex structure $J_\alpha$ on $N_D$ as in (1.2). The local GW invariants of $D$ are the invariants associated
with the space

\[ \overline{\mathcal{M}}_{g,n}^{J_{\alpha}}(N_D, d) \]

of all stable \( J_{\alpha} \)-holomorphic maps \( f : C \to N_D \) whose domain has genus \( g \) and \( n \) marked points and whose image represents \( d[D] \in H_2(N_D) \). By Proposition 1.1 this is the same as the space \( \overline{\mathcal{M}}_{g,n}(D,d) \) of stable \( J \)-holomorphic maps into the zero section \( D \) with degree \( d \). However, the linearizations of these equations differ in a way that will be crucial in later sections.

**Lemma 1.2.** If \( D \) has genus \( h \geq 1 \) and \( 2g + n \geq 3 \), then the domain of every map in \( \overline{\mathcal{M}}_{g,n}(D,d) \) is a stable curve.

**Proof.** When \( D \) has genus \( h \geq 1 \) all rational components of the domain are mapped to points, so are stable curves (by the definition of stable map). Similarly, all components with genus one are mapped to points or have a node (so are stable), unless the domain is smooth and the map is etale, in which case the domain has at least one marked point since \( 2g + n \geq 3 \).

In particular, because all domains are stable, the relative cotangent bundles over \( \overline{\mathcal{M}}_{g,n}(D,d) \) are pull-backs of the relative cotangent bundles over \( \overline{\mathcal{M}}_{g,n} \) by the stabilization map. The descendent classes are thus pull-backs of cohomology classes via the map (0.4).

One usually takes \( \overline{\mathcal{M}}_{g,n} \) to be a Deligne-Mumford space. However, it is more convenient to take it to be the moduli space described by Abramovich, Corti and Vistoli [ACV], building on the key work of Looijenga [Lo]. This is a finite branched cover of the compactified Deligne-Mumford space that is a fine moduli space and a smooth projective variety ([ACV, Theorem 7.6.4]); it solves the moduli problem for families of “\( G \)-twisted curves” that carry a principle \( G \)-bundle for a certain finite group \( G \) together with certain additional structure at their nodes and marked points (see [ACV] for details). As described in [IP1, Section 1], this modification has no substantial effect: one recovers the standard GW invariants by dividing by the degree of the cover. Accordingly, we will use the standard notation \( \overline{\mathcal{M}}_{g,n} \) for compactified Deligne-Mumford space and leave the presence of twisted structures implicit. In this context, the space \( \overline{\mathcal{M}}_{g,n} \) of \( G \)-twisted curves and the total space of its universal curve

\[ \overline{U}_{g,n} \]

\[ \xrightarrow{\pi} \overline{\mathcal{M}}_{g,n} \]

are manifolds with Riemannian metrics.
Throughout, we will work with the moduli spaces of solutions of perturbations of (1.4), namely, solutions of the perturbed $J_\alpha$-holomorphic map equation
\begin{equation}
\overline{\partial}_J f - K_\alpha(\partial_J f)j = \nu_f
\end{equation}
for various perturbation terms $\nu$. We will use perturbations of the type introduced by Ruan and Tian in [RT2], which can be described as follows. Fix an almost complex manifold $(X,J)$ and let $\overline{U}$ be the universal curve (1.7). Because $G$-twisted curves have no non-trivial automorphisms, the domain of a map $f : C \to X$ is uniquely identified (as a $G$-twisted curve) with a fiber of $U$, and the graph of $f$ is a map $F : C \to \overline{U} \times X$. Consider the bundle $T^*\overline{U} \boxtimes TX = \text{Hom}(\pi_1^*T\overline{U}, \pi_2^*TX)$ over $\overline{U} \times X$. A Ruan-Tian perturbation is an element $\nu$ of the space $P = \Omega^{0,1}_J(T^*\overline{U} \boxtimes TX)$ of $(0,1)$ sections, that is, sections $\nu$ satisfying $\nu \circ j_u = - J \circ \nu$ where $j_u$ is the complex structure on $U$. Here, and everywhere below, $(0,1)$ components are determined by $J$, not $J_\alpha$. Restricting such a $\nu$ to the graph of $f$ gives a form $\nu_f \in \Omega^{0,1}(f^*TX)$, defined by
\begin{equation}
\nu_f(x)(u) = v(x, f(x))(u) \quad \forall x \in C, \ u \in T_xC,
\end{equation}
that can be used in (1.8). Note that $\nu_f$ depends on $f$, but not on $df$.

We will routinely use the phrase “for generic $\nu$” to mean “for $\nu$ in a Baire set in the space $P$”.

2. Convergence of maps with stable domains. The proof of the main theorem requires a careful definition of the space of maps as a topological space. The appropriate topology is not the one defined by Gromov compactness. Instead, we will use the stronger “$\lambda$-topology” defined by carefully-chosen weighted Sobolev norms. In this section, we set out the definitions and then prove that Gromov compactness holds in the $\lambda$-topology.

Let $\pi : \overline{U} \to \overline{M}_{g,n}$ be the universal $G$-twisted curve (1.7). There is a $\delta_0 > 0$ such that in each fiber $C_z = \pi^{-1}(z)$ the nodes are separated from each other and from the marked points by a distance of at least $4\delta_0$. We will scale the metric so that $\delta_0 = 1$ and choose a continuous function
\begin{equation}
\rho : \overline{U} \to \mathbb{R}
\end{equation}
that is equal to the distance to the nodal variety on the set $\{\rho < 1\}$ and satisfies $1 \leq \rho \leq 2$ on the complementary set. For each $\delta < 1$ we will also write
\begin{equation}
C_z(\delta) = C_z \cap \{\rho \geq \delta\} \quad \text{and} \quad B_z(\delta) = C_z \cap \{\rho < \delta\}.
\end{equation}
For small $\delta$, $B_z(\delta)$ is a union of components, each being either a union of two disks with their center points identified (a node) or a thin annular neck (a near node).
Because the universal $G$-twisted curve (1.7) is a fine moduli space, the fibers have no non-trivial automorphisms and:

(i) Around each smooth fiber $C_z$ there is a neighborhood $V_z$ of $z$ and smooth local trivialization

$$\phi : C_z \times V_z \longrightarrow U_z.$$  

(ii) Around each fiber $C_z$ with $B_z(\delta) \neq \emptyset$ there is a similar local trivialization

$$\phi : C_z(\delta) \times V_z \longrightarrow U_z$$

where $U_z = \pi^{-1}(V_z) \cap \{\rho > \delta\}$.

Now fix an isometric embedding of $X$ into $\mathbb{R}^N$ for some $N$. The space of maps is defined using the following weighted Sobolev norms.

Definition 2.1. Fix a constant $\lambda$ with $0 < \lambda < \frac{1}{6}$. For each $p \geq 2$ and each curve $C$, let $\text{Map}_\lambda(C, X)$ be the completion of the set of smooth maps $f : C \rightarrow X$ in the weighted norm

$$\|f\|_{1,p} = \left( \int_C \rho^{p-2-\lambda} |df|^p \right)^{\frac{1}{p}} + \left( \int_C \rho^{-\lambda} |df|^2 \right)^{\frac{1}{2}} + \left( \int_C |f|^p \right)^{\frac{1}{p}}.$$

where $|f|$ is defined by the embedding $X \subset \mathbb{R}^N$, and both $|df|$ and the measure on $C$ are defined using the Riemannian metrics on $C$ and $X$ induced from the metrics on $\overline{U}$ and $\mathbb{R}^N$.

If we replace $C$ by $C_z(\delta)$ in the Definition 2.1 then the resulting norms are uniformly equivalent, for each $\delta$, to the usual $L^{1,p}$ norm on the fibers of the local trivializations (2.3) and (2.4). After fixing $p$, we also define the $p$-energy $E_p(f)$ and total energy $E(f)$ of a map $f : C \rightarrow X$ to be

$$E(f) = E_p(f) + E_2(f)$$

where $E_p(f) = \left( \int_C \rho^{p-2-\lambda} |df|^p \right)^{\frac{2}{p}}$.

We will consider only the subset of $\text{Map}_\lambda(X)$ whose total energy is below a fixed level.

Definition 2.2. (\lambda-topology) For each number $E$ and $p > 2$, set

$$\text{Map}_{g,n}^E(X) = \\{(z, f) \mid z \in \overline{M}_{g,n}, f \in \text{Map}_\lambda(C_z, X) \text{ and } E(f) < E\}.$$

Give this space the $\lambda$-topology: a sequence $(C_n, f_n)$ converges to $(C, f)$ if (a) $C_n \rightarrow C$ in $\overline{M}_{g,n}$, (b) $E_p(f_n) \rightarrow E_p(f)$ and $E_2(f_n) \rightarrow E_2(f)$, and (c) $f_n \rightarrow f$ in the norm (2.5) on $C_z(\delta)$ for every $\delta > 0$.

The convergence in (c) is defined using the trivialization (2.4). For simplicity, we will often denote the space (2.7) by $\text{Map}_\lambda(X)$. 
When working with the norm (2.5) on curves $C_z$ near a nodal fiber $C_0$ of the universal curve, it is helpful to use the definitions (2.2) to decompose $C_z$ into the "thick" region $C_z(\delta)$ away from the nodes, and the "thin" regions $B_{z,i}(\delta) \subset C_z$ that lie within distance $\delta$ from one of the nodes $n_i$ of $C_0$. The thin regions are of two types—nodes and necks—described as follows.

Near a node $n_i$ of $C_0$, choose holomorphic coordinates $\{x_i\}$ on the universal curve such that

$$B_{z,i}(\delta) = \left\{(x_1, \ldots, x_n) \mid x_1 x_2 = \mu, \ x_j = c_j \ \forall \ j > 2, \text{ and } |x_1|^2 + |x_2|^2 < \delta \right\}$$

(2.8)

for some constants $\mu, c_j \in \mathbb{C}$. For notational simplicity, we will often omit the subscript $z$ in $C_z(\delta)$ and $B_{z,i}(\delta)$.

- **(Nodes)** When $\mu = 0$, $B_{i}(\delta)$ is diffeomorphic to two disks $D^1(\delta)$ and $D^2(\delta)$ with their center points identified. The punctured disk $D^1(\delta) \setminus \{0\}$ can be parameterized by the map

$$\phi : (t, \theta) \mapsto (e^{-\frac{t}{2} - i\theta}, 0, c_3, \ldots)$$

(2.9)

from the half-infinite cylinder $T^1 = (-L, L) \times S^1$ where $L = -\ln \delta$. Composing $\phi$ with $x_1 \leftrightarrow x_2$ gives a parameterization of $D^2(\delta) \setminus \{0\}$. Together, $B_{i}(\delta) \setminus \{0\}$ is parameterized by a disjoint union $T(\delta) = T^1 \cup T^2$ of two cylinders.

- **(Necks)** When $\mu \neq 0$, $B_{i}(\delta)$ can be parameterized by the map

$$\phi : (t, \theta) \mapsto \left(x_1, \frac{\mu}{x_1}, c_3, \ldots \right) \ \text{where} \ x_1 = \sqrt{|\mu|} e^{t+i\theta}$$

(2.10)

from the cylinder $T(\delta) = (-L, L) \times S^1$ for the unique positive $L$ that satisfies $2|\mu| \cosh(2L) = \delta^2$. Note that $L \to \infty$ as the neck pinches.

To obtain uniform estimates, it is useful to express the norm (2.5) in the parameterizations (2.9) and (2.10). In the coordinate chart used in (2.8), the metric on $\overline{U}$ is uniformly equivalent to the Euclidean metric $g_0$ in these coordinates, and the distance function is uniformly equivalent to the Euclidean distance. Furthermore, under the maps (2.9) and (2.10) $g_0$ is conformally related to the cylindrical metric $\hat{g} = dt^2 + d\theta^2$ by

$$\phi^* g_0 = \rho^2 \hat{g} \ \text{where} \ \rho^2 = \begin{cases} e^{-2t} & \text{near a node} \\ 2|\mu| \cosh(2t) & \text{in a neck.} \end{cases}$$

(2.11)

Consequently, after identifying $f$ and $\rho$ with their $\phi$-pullbacks we have, for both nodes and necks and for each $p \geq 2$,

$$\int_{B_{i}(\delta)} \rho^{p-2-\lambda} |df|^p \ dvol_g \cong \int_{T(\delta)} \rho^{-\lambda} |df|^p \ dvol_{\hat{g}}$$

(2.12)

where $\cong$ means that the ratio between the two sides is bounded above and below by positive constants that depend only on $p$ and $\lambda$. It is useful to note that, because
\( \rho \) is essentially exponential in \( t \), the integrals of its powers in the cylindrical metric satisfy

\[
\int_{\rho \leq \delta} \rho^\gamma \, dt \, d\theta \leq c_\gamma \delta^\gamma \quad \text{for } \gamma > 0.
\]

The following two lemmas give properties of maps in \( \text{Map}_{g,n}^E(X) \). The first shows that the images of necks and nodal neighborhoods are uniformly small, and the second shows that when two maps are close in the \( \lambda \)-topology then the Hausdorff distance \( \text{dist}_H \) between their images is small.

**Lemma 2.3.** Fix \( g, n, E \) and \( p > 2 \). Then there are constants \( \delta_0 > 0 \) and \( c \) such that for every \( (C, f) \in \text{Map}_{g,n}^E(X) \) and every \( \delta < \delta_0 \), each component \( B_i(\delta) \) of \( B(\delta) \subset C \) satisfies

\[
\text{diam} \left( f\left( B_i(\delta) \right) \right) \leq c \delta^\lambda.
\]

**Proof.** By the compactness of \( \overline{U} \), there is a \( \delta_0 > 0 \) so that whenever \( \delta < \delta_0 \) there is a nodal fiber \( C_0 \) of \( \overline{U} \) and holomorphic coordinates centered on a node \( n_i \in C_0 \) so that \( B_i(\delta) \) is given by (2.8). Identifying \( f : B_i(\delta) \to X \) with its \( \phi \)-pullback \( f : T \to X \subset \mathbb{R}^N \) as in (2.9) or (2.10), we have

\[
\text{diam} \left( f\left( B_i(\delta) \right) \right) = \text{diam} \left( f\left( T \right) \right) = \text{osc} \left( f \right).
\]

In the node case, the Sobolev inequality \( \text{osc} \left( f \right) \leq c_1 \| df \|_p \) holds on each segment \( T_n = [L + n, L + n + 1] \times S^1 \) of \( T \), and (2.11) implies that \( \rho \leq c_2 \delta e^{-n} \) on \( T_n \). Summing from \( n = 1 \) to \( \infty \) yields

\[
\text{diam} \left( f\left( B_i(\delta) \right) \right) \leq c_3 \sum_n \left( \int_{T_n} (\delta e^{-n} \rho^{-1})^\lambda \| df \|_p^p \right)^{1/p} \\
\leq c_3 \delta^\lambda \sum_n e^{-n \lambda/p} \left( \int_T \rho^{-\lambda} \| df \|_p^p \right)^{1/p} \leq c_4 \sqrt{E} \delta^\lambda
\]

using (2.6) and (2.12). The same argument applies in the neck case, noting that (2.11) again implies that \( \rho \leq c_5 \delta e^{-n} \) on both \( T_n = [L - n - 1, L - n] \times S^1 \) and on \( T'_n = [-L + n, -L + n + 1] \times S^1 \) for \( 0 \leq n < L \). \( \square \)

**Lemma 2.4.** Fix \( g, n, E \) and \( p > 2 \). Given \( (C_0, f) \in \text{Map}_{g,n}^E(X) \), \( \varepsilon > 0 \) and a sufficiently small \( \delta > 0 \), there are neighborhoods \( N_f(\varepsilon) \) and \( N_f(\varepsilon, \delta) \) of \( (C_0, f) \) in the \( \lambda \)-topology such that

\[
\text{dist}_H \left( f(C_0), g(C) \right) \leq \varepsilon \quad \text{for all } (C, g) \in N_f(\varepsilon)
\]

and

\[
\| f - g \|_{\infty, C_0(\delta)} \leq \varepsilon \quad \text{for all } (C, g) \in N_f(\varepsilon, \delta).
\]
Proof. By Lemma 2.3 we can choose $\delta_1 > 0$ so that $\text{diam}(f(B_i(\delta_1))) \leq \varepsilon/3$ for all $f \in \text{Map}^E_{g,n}(X)$. Fix $\delta$ with $2\delta \leq \delta_1$. We can then choose a neighborhood $\mathcal{N}_f$ of $(C_0, f)$ small enough so that the domains of all maps $g : C \to X$ in $\mathcal{N}_f$ lie in the uniform local trivialization (2.4) around $C_0$ for this $\delta$. Decompose the domain $C_0$ of $f$ into $C_0(\delta)$ and the union of neighborhoods $B_i(\delta)$ of its nodes. Then for each $(C, g) \in \mathcal{N}_f$ we have $\delta \leq \rho \leq 2$ on $C(\delta)$, so the norm (2.5) is uniformly equivalent to the (unweighted) $L^{1,p}$ norm on $C(\delta)$. Furthermore, the fibers of the local trivialization (2.4) have uniform geometry, so there is a uniform constant (depending on $\delta$) for the usual Sobolev embedding $C^0 \subset L^{1,p}$. Consequently,

$$\|f - g\|_{\infty; C_0(\delta)} \leq c(\delta) \|f - g\|_{1,p}.$$  

We can then choose $\mathcal{N}_f(\varepsilon, \delta)$ to make the right-hand side less than $\varepsilon/3$ for all $g \in \mathcal{N}_f(\varepsilon, \delta)$. In particular, setting $\mathcal{N}_f(\varepsilon) = \mathcal{N}_f(\varepsilon, \delta_1/2)$, each $g \in \mathcal{N}_f(\varepsilon)$ satisfies

$$\text{dist}_H(f(C_0), g(C)) \leq \|f - g\|_{\infty; C_0(\delta)} + \sup_i \text{diam} f(B_i(\delta)) + \sup_i \text{diam} g(B_i(\delta))$$

$$\leq \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3}.$$  

We next prove an enhanced version of the Gromov Compactness Theorem. It assumes that all maps have stable domains (cf. Lemma 1.2), and proves convergence in the $\lambda$-topology, which is stronger than the convergence in the standard formulations of Gromov Compactness (cf. [FO, IS2, RT2]).

**Theorem 2.5.** (Compactness) Suppose that all maps in $\overline{M}^{J,\nu}_{g,n}(X, A)$ have stable domains. Then there is an $E = E(p,g,n,A)$ such that $\overline{M}^{J,\nu}_{g,n}(X, A)$ is a compact subset of $\text{Map}^E(X)$ whenever $\sup |\nu|$ is small.

**Proof.** Given a sequence of maps $f_k : C_k \to X$ in $\overline{M}^{J,\nu}_{g,n}(X, A)$ we can consider their graphs $F_k : C_k \to \overline{U} \times X$ as described before equation (1.9). Then $\{F_k\}$ is a sequence of $J_{\nu}$-holomorphic maps with uniformly bounded energy. Moreover, as explained in Section 1, each $C_k$ is a stable curve with no non-trivial automorphisms. The first factor of each $F_k$ is therefore a diffeomorphism onto a fiber of the universal curve. The Gromov Compactness Theorem [IS2], applied to $\{F_k\}$ implies that there is a subsequence such that (i) the domains $C_k$ converge in $\overline{U}$ to a limit $C_0$, (ii) the maps $f_k$ converge to a limit $f_0$ in Hausdorff distance and in $L^{1,p}$ on compact sets in the complement of the nodes of $C_0$, and (iii) the energy densities $|dF_k| dvol$ converge as measures.

Next fix $\delta \leq 1$ small enough so that the maps (2.10) are defined on the $2\delta$-neighborhoods of the nodes. Because the energy densities converge as measures we can, given any $\varepsilon_0 > 0$, also assume that, for each node $n_i$ of $C_0$, the energy in each neck $B_{k,i}(\delta)$ of each $C_k$ is at most $\varepsilon_0$. But energy is conformally invariant
so, as in (2.12) with \( p = 2 \), the pullback maps \( f_k : T(\delta) \to X \) satisfy the \((J, \nu)\)-holomorphic map equation and

\[
(2.14) \quad \int_{T(\delta)} |df_k|^2 = \int_{B_{k, \delta}} |df_k|^2 < \varepsilon_0.
\]

Elliptic theory then gives a pointwise bound on \( |df_k| \): by Lemma 5.1 of [IP2] there are constants \( c_1 \) and \( \varepsilon_0 \) so that whenever (2.14) holds we have \( |df_k| < c_1 \rho^{1/3} \) on \( T(\delta) \); both \( c_1 \) and the maximum number of nodes depend only on \( g, n, A \) and \( \sup |\nu| \). Integrating as in (2.12) and (2.13) shows that for any \( p \geq 2 \) and \( \lambda < \frac{1}{6} \)

\[
(2.15) \quad \int_{B_{k, \delta}} \rho^{p-2-\lambda} |df_k|^p \leq c_2 \int_{T(\delta)} \rho^{-\lambda} |df_k|^p \leq c_2 c_1 \int_{T(\delta)} \rho^{-\lambda + \frac{2}{3}} \leq c_3 \delta^{\frac{2}{3} - \lambda} \leq c_3 \sqrt{\delta}.
\]

This, together with the convergence on each \( C(\delta) \), implies that \( E_p(f_k) \to E_p(f_0) \), that \( E_2(f_k) \to E_2(f_0) \), and that there is a bound \( E(f) \leq E \) for all \((J, \nu)\)-holomorphic maps \( f \). Convergence in the \( \lambda \)-norm also follows: given \( \varepsilon > 0 \), choose \( \delta \) small enough that the bound (2.15) is less than \((\varepsilon/4)^p\) and less than \((\varepsilon/4)^2\) when \( p = 2 \). By the compactness of \( X \subset \mathbb{R}^N \) the integral of \( |f|^p \) over \( B(\delta) \) is bounded by \( c_4 \text{Area}(B(\delta)) \leq c_5 \delta^2 \); we can also assume this is less than \((\varepsilon/4)^p\). Finally, for this \( \delta \), the restriction of the norm (2.5) to \( C(\delta) \) is uniformly equivalent to the unweighted \( L^1 \)-norm, so we can choose \( K \) large enough so that, for all \( k \geq K \), we have \( \|f_k - f_0\|_{1,p,C(\delta)} < \varepsilon/4 \), and hence \( \|f_k - f_0\|_{1,p} < \varepsilon \). \( \square \)

3. The virtual fundamental class. Gromov-Witten invariants of a closed symplectic manifold \( X \) have been defined in several different ways. When \( X \) is a smooth complex curve (the only case needed for this paper), all definitions apply and yield the same GW invariants. Each definition involves compact moduli spaces \( \overline{M}_{g,n}(X, A) \) of (formal) dimension \( r = c_1(X)(A) + (\dim X - 3)(1 - g) + n \) and the associated map

\[
(3.1) \quad \widehat{ev} = st \times ev : \overline{M}_{g,n}(X, A) \to \overline{M}_{g,n} \times X^n
\]

defined as in (0.4). For our purposes, three different descriptions are relevant. One is algebraic and the other two are analytic:

1. When \( X \) is projective, the space of stable maps \( \overline{M}^{\text{stable}}_{g,n}(X, A) \) is a projective variety and algebraic geometers (see [LT1, BF]) define the virtual fundamental class \( [\overline{M}_{g,n}(X, A)]^{\text{virt}} \) as an element of its Chow cohomology:

\[
(3.2) \quad [\overline{M}_{g,n}(X, A)]^{\text{virt}} \in A_r(\overline{M}^{\text{stable}}_{g,n}(X, A)).
\]

2. When \( X \) is symplectic and semipositive, Ruan-Tian [RT2] showed that for generic \((J, \nu)\) the space \( \overline{M}^{(J, \nu)}_{g,n}(X, A) \) of all \((J, \nu)\)-holomorphic maps is the
union of (i) a $2r$-dimensional orbifold $\mathcal{M}$ consisting of maps from smooth domains and (ii) a stratified “boundary” whose image under the map (3.1) lies in a set of dimension at most $2r - 2$. Consequently, the image of the moduli space represents a rational homology class

$$GW_{g,n}(X,A) \in H_{2r}(\overline{\mathcal{M}}_{g,n} \times X^n; \mathbb{Q}).$$

This Ruan-Tian GW class is independent of the generic $(J,\nu)$ and is a symplectic invariant of $X$. (“Semipositive” is a technical condition that is true whenever $\dim X \leq 6$.)

(3) When $X$ is symplectic, the construction of Li-Tian [LT2] defines a virtual fundamental class

$$[\overline{\mathcal{M}}_{g,n}(X,A)]^{\text{vir}} \in H_{2r}(Map_{g,n}(X,A); \mathbb{Q})$$

in the homology of the infinite-dimensional space of maps $Map_{g,n}(X,A)$. Because (3.1) extends to $Map_{g,n}(X,A)$ one can then evaluate the class (3.4) on classes in $H^*(\overline{\mathcal{M}}_{g,n} \times X^n)$.

Variations on construction 3 have been done by Fukaya-Ono [FO], Ruan [R] and Siebert [S].

When $X$ is projective, Li and Tian proved in [LT3] that the virtual class (3.4) is the homology class underlying the Chow class (3.2) under the inclusion of the space of stable maps into $Map_{g,n}(X,A)$. When $X$ is semipositive, one can show that the pushforward of the virtual class (3.4) by $\hat{ev}_*$ is the Ruan-Tian class (3.8); we explicitly prove this for compact curves in Remark 10.2. Thus when $X$ is a smooth compact curve $D$, all three definitions apply and, after pushing forwards by $\hat{ev}_*$, define the same element in the homology of $\overline{\mathcal{M}}_{g,n} \times X^n$.

Later, to prove the Main Theorem stated in the introduction, we will work with the GW invariants defined by equation (3.3). In preparation, we now describe one version of the construction in the relevant case: when the domains of all $(J,\nu)$-holomorphic maps have no non-trivial automorphisms (cf. Section 1). In this case, for generic $(J,\nu)$, each stratum in the moduli space

$$\overline{\mathcal{M}} = \overline{\mathcal{M}}_{g,n}(X,A)$$

(including the “top stratum” $\mathcal{M}$) is a smooth oriented manifold, the boundary $\partial \overline{\mathcal{M}} = \overline{\mathcal{M}} \setminus \mathcal{M}$ is compact, and $\hat{ev}$ restricts to a smooth map to the compact oriented manifold $\overline{\mathcal{M}}_{g,n} \times X^n$ on each stratum. The Ruan-Tian invariant can be defined, using arguments of Kronheimer and Mrowka, by deleting a neighborhood of the boundary and considering the resulting relative homology class, as follows.

First, a simple compactness and transversality argument (see the first paragraph of the proof of Proposition 4.2 in [KM]) shows that there is an open neighborhood $U$ of the image $\hat{ev}(\partial \overline{\mathcal{M}})$ satisfying:

(a) $U$ is a smooth manifold with boundary and $\hat{ev}|_{\mathcal{M}}$ is transverse to $\partial U$, and
(b) there is a (finite) basis for $H_{\ell-2r}(\overline{M}_{g,n} \times X^n; \mathbb{Q})$ represented by cycles disjoint from $\overline{U}$; here $\ell$ is the dimension of $\overline{M}_{g,n} \times X^n$.

**Definition 3.1.** Given a moduli space (3.5), choose a set $U$ as above and let $\overline{M}_U \subset \mathcal{M}$ be the closed set

$$\overline{M}_U = \overline{M} \cap \tilde{\ev}^{-1}(\overline{M}_{g,n} \times X^n \setminus U) \subset \mathcal{M}. \tag{3.6}$$

It follows from (a) above that $\overline{M}_U$ is a compact oriented manifold with boundary, and thus carries a fundamental class in relative homology that we denote by $[\overline{M}_U] \in H_{2r}(\overline{M}_U, \partial \overline{M}_U; \mathbb{Q})$.

On the other hand, the inclusion of the pairs $k : (\overline{M}_{g,n} \times X^n, \emptyset) \to (\overline{M}_{g,n} \times X^n, \overline{U})$ induces a map in homology

$$k_* : H_{2r}(\overline{M}_{g,n} \times X^n; \mathbb{Q}) \longrightarrow H_{2r}(\overline{M}_{g,n} \times X^n, \overline{U}; \mathbb{Q}).$$

Proposition 4.2 of [KM] then implies that there is a unique homology class $[\tilde{\ev}(\overline{M})]$ with

$$k_* [\tilde{\ev}(\overline{M})] = \tilde{\ev}_* [\overline{M}_U]. \tag{3.7}$$

In fact, [KM] showed that there is a rational singular smooth cycle $B$ that represents $[\tilde{\ev}(\overline{M})]$ and agrees with $\tilde{\ev}(\overline{M}_U)$ outside of $U$. The uniqueness then follows from property (b) above because the inclusion

$$H_{2r}(\overline{U}; \mathbb{Q}) \longrightarrow H_{2r}(\overline{M}_{g,n} \times X^n; \mathbb{Q})$$

is trivial and hence $k_*$ is injective. The class $[\tilde{\ev}(\overline{M})] = [B]$ is the GW class:

**Lemma 3.2.** With $U$ and $\overline{M}_U$ as above, the Ruan-Tian GW class is the unique rational homology class satisfying (3.7), namely

$$GW_{g,n}(X, A) = [\tilde{\ev}(\overline{M})] \in H_{2r}(\overline{M}_{g,n} \times X^n; \mathbb{Q}). \tag{3.8}$$

In particular, $[\tilde{\ev}(\overline{M})]$ is independent of the choice of $U$ and the generic $(J, \nu)$.

**Proof.** For each $\gamma \in H^{2r}(\overline{M}_{g,n} \times X^n; \mathbb{Q})$, Ruan and Tian choose a representative $\Gamma$ of the Poincaré dual of $\gamma$ with $\Gamma$ transversal to $\tilde{\ev}(\overline{M})$ and disjoint from $\tilde{\ev}(\partial \overline{M})$. They defined $GW_{g,n}(X, A)(\gamma)$ as $\tilde{\ev}(\overline{M}) \cap \Gamma$ and showed these numbers are independent of the various choices made. But by property (b) above, we can assume that $\Gamma$ is a linear combination of cycles that do not intersect $\overline{U}$. Then the geometric intersection $\tilde{\ev}(\overline{M}) \cap \Gamma$ is the same as $B \cap \Gamma$, which represents $[B](\gamma) = [\tilde{\ev}(\overline{M})](\gamma)$. \qed
In our case, \( X = N_D \) is the total space of the spin curve \((D, N)\). By the Image Localization Lemma 1.1, for small generic \( \nu \) there is a \( \epsilon \)-neighborhood \( N_D(\epsilon) \) of the zero section \( D \) in \( N_D \) such that every \((J_\alpha, \nu)\)-holomorphic map has its image in that neighborhood. Although \( N_D(\epsilon) \) is not compact, it is a manifold with boundary and Lemma 3.2 still applies (again by Proposition 4.2 of [KM]). Thus the image of the moduli space represents a rational homology class

\[
GW_{g,n}^{loc}(N_D, d) := \bar{\ev}_n\left( \overline{M}_{g,n}(N_D, d[D]) \right) \in H_{2\beta+2n}(\overline{M}_{g,n} \times N^n_D; \mathbb{Q}).
\]

Here the number \( \beta \), which will occur frequently in our dimension counts, is given in terms of the degree \( d \) of the map and the genus \( h \) of \( D \) by

\[
\beta = d(1 - h) + g - 1.
\]

The class (3.9) is the local GW class of the spin curve \((D, N)\). As shown in [LP], for given \( g, n, d \) and \( h \), it depends only on the parity \( h^0(N) \).

4. The linearization operator. We now return to the specific situation in which the local GW invariants are defined. Thus, as described after Lemma 1.1, we consider \( J_\alpha \)-holomorphic maps into the total space \( N_D \) of a spin bundle \( N \to D \) over a curve \( D \). This section shows how the special form of the \( J_\alpha \)-holomorphic map equation implies vanishing theorems for the linearized operator. Along the way we introduce a family of operators that extends the relevant component of the linearization to general maps.

A neighborhood \( U \) of the zero section \( D \subset N_D \) can be identified with a neighborhood of the zero section in the projectivization \( \mathbb{P}(N \oplus \mathcal{O}_D) \) by a fiber-preserving biholomorphism. Since \( \mathbb{P}(N \oplus \mathcal{O}_D) \) is Kähler we can use this identification to define a Kähler structure on \( U \). With this Kähler structure, the exact sequence (1.5) of the underlying complex vector bundle splits as \( TN_D = \pi^*TD \oplus \pi^*N \). We will often write this simply as

\[
TN_D = TD \oplus N,
\]

leaving the pullbacks as understood; we will then call \( TD \) and \( N \) the “horizontal” and “vertical” subbundles, respectively. In this and the following sections \( \nabla \) will denote the covariant derivative on \( N \) induced by the Levi-Civita connection of the Kähler manifold \( N_D \), that is, \( \pi_N \circ \nabla^{LC} \) where \( \pi_N \) is the orthogonal projection onto the vertical component of (4.1).

Let \( f : C \to N_D \) be a map from a smooth domain \( C \). The linearization of the left-hand side of (1.4) defines an operator

\[
D_f : \Gamma(f^*TN_D) \oplus H^{0,1}(C, TC) \to \Gamma(A^{0,1}(f^*TN_D))
\]

given by \( D_f(\xi, k) = \tilde{L}_f \xi + \frac{1}{2}(J - K_\alpha)df k \). The operator \( \tilde{L}_f \) arises from the variation in the map with the complex structure on \( C \) held fixed, and the second term

\[\text{second term}\]
arises from the variation $k$ of the complex structure on $C$. Under the splitting (4.1), \( \hat{L}_f \) decomposes as

\[
\hat{L}_f = \begin{pmatrix} \overline{\partial}_f^T & A \\ B & \overline{L}_f \end{pmatrix} : \Omega^0(f^*TD) \oplus \Omega^0(f^*N) \longrightarrow \Omega^{0,1}(f^*TD) \oplus \Omega^{0,1}(f^*N)
\]

where $A$ and $B$ are certain bundle maps. For $\xi \in \Gamma(f^*N)$ and $v \in TC$, the component $\overline{L}_f$ is given by

\[
\overline{L}_f \xi(v) = \frac{1}{2} \pi_N [\nabla_v \xi + J \nabla_{jv} \xi - \nabla_\xi K_\alpha (df(jv) + J df(v)) - K_\alpha (\nabla_{jv} \xi + J \nabla_v \xi)].
\]

If the image of $f$ lies in $D$ then $K_\alpha$ vanishes and, by [LP, Lemma 8.2b], the $\nabla K_\alpha$ term lies in $f^*N$. Thus this operator reduces to

\[
(4.2) \quad \overline{L}_f = \overline{\partial}_f - \frac{1}{2} \nabla K_\alpha (df - J df j) j
\]

where $\overline{\partial}_f$ is the $\overline{\partial}$-operator on $f^*N$.

**Definition 4.1.** To each map $f : C \to N_D$, we associate the “modified linearization operator” $L_f : \Omega^0(f^*N) \to \Omega^{0,1}(f^*N)$ given by

\[
(4.3) \quad L_f = \overline{\partial}_f + R_\alpha \quad \text{where} \quad R_\alpha = -\frac{1}{2} \pi_N [\nabla K_\alpha (df - J df j) j].
\]

If $f$ is a $J_\alpha$-holomorphic map—or is any other map whose image lies in the zero divisor—then $L_f$ is the vertical-to-vertical component (4.2) of the linearized $J_\alpha$-holomorphic map equation. Furthermore, if $f$ is $J_\alpha$-holomorphic, Lemma 8.2 of [LP] shows that $R_\alpha : f^*N \to T^*C \otimes f^*N$ is the complex anti-linear bundle map defined by $R_\alpha(\xi) = -\nabla_\xi K_\alpha \circ df \circ j$. Thus

\[
f \mapsto L_f \quad \text{is a family of operators parameterized by maps that agrees with } \overline{L}_f \quad \text{along the moduli space of } J_\alpha \text{-holomorphic maps}.
\]

Much of the rest of this paper will be devoted to understanding the analytic properties of this family of operators.

For a map $f : C \to N_D$ whose domain $C$ is a connected nodal curve, we will regard $L_f$ as an operator on a function space that can be described in terms of the normalization $\pi : \tilde{C} \to C$. The inverse image of each node $n_i \in C$ is a pair of points $p_i, q_i \in \tilde{C}$. For each component $\tilde{C}_k$ of the normalization, let $E_{k,f}$ be the space $\Omega^0(\tilde{C}_k, \pi^* f^*N)$ of smooth sections of $\pi^* f^*N$ on $\tilde{C}_k$, and similarly let $F_{k,f} = \Omega^{0,1}(\tilde{C}_k, \pi^* f^*N)$. Combine these by setting

\[
(4.4) \quad E_f = \bigoplus_k E_{k,f} \quad \text{and} \quad F_f = \bigoplus_k F_{k,f}.
\]
Formula (4.3) then defines an operator
\[ L_f : E_f \longrightarrow F_f \]  
whose restriction to each component \( \tilde{C}_k \) gives operators \( L_{k,f} : E_{k,f} \rightarrow F_{k,f} \) as in (4.3). Using Riemann-Roch (cf. [FO, Lemma 12.2]) one obtains
\[ \text{index } L_f = -2\beta \]  
where \( \beta \) is given by (3.10).

In general, as \( f \) varies over the space of stable maps, one expects the dimensions of the kernels of these operators to jump, with compensating jumps in the dimensions of the cokernels. But the following theorem shows that this does not happen for the operators \( L_f \) as \( f \) varies over the space of \( J_\alpha \)-holomorphic maps. This second remarkable fact about the \( J_\alpha \)-holomorphic map equation plays a crucial role in our analysis. It implies, as we will show in Sections 5–8, that cokernels of the operators \( L_f \) form vector bundles over \( \overline{M}_{g,n}(D,d) \).

\textbf{VANISHING THEOREM 4.2.} For each \( J_\alpha \)-holomorphic map \( f : C \rightarrow D \) in \( \overline{M}_{g,n}(D,d) \) with \( d \neq 0 \)
\[ \ker L_f = 0 \quad \text{and} \quad \dim \coker L_f = 2\beta. \]

\textit{Proof.} Let \( d_k \) be the degree the restriction of \( f \) to one component \( \tilde{C}_k \) of the normalization of \( C \). If \( d_k \neq 0 \), \( L_{k,f} \) is injective by [LP, Proposition 8.6]. On the other hand, when \( d_k = 0 \), the operator \( L_{k,f} \) is the \( \overline{\partial} \)-operator on the trivial bundle whose kernel is the constant functions. Since any solution of \( L_f \xi = 0 \) restricts to a solution of \( L_{k,f} \xi = 0 \) on \( \tilde{C}_k \), \( \xi \) vanishes on each component with \( d_k \neq 0 \) and is constant on each component with \( d_k = 0 \). But \( \xi \) is continuous at each node, so \( \xi \equiv 0 \). This shows \( L_f \) is injective and hence the dimension of its cokernel is the negative of its index (4.6). \( \square \)

5. The bundles \( E \) and \( F \). We now pass to the level of global analysis by completing the spaces \( E_f \) and \( F_f \) in (4.5) in appropriate Sobolev norms. As \( f \) varies, these define spaces \( E \) and \( F \), each with a projection to the space of map whose fibers are vector spaces and the modified linearization operator (4.5) defines a map \( L : E \rightarrow F \) that is linear on fibers. However, it is not clear whether \( E \) and \( F \) are vector bundles—they may fail to be locally trivial over maps with nodal domains. We will return to the issue of local triviality in the Section 8. Here, in preparation, we define weighted Sobolev norms and show that \( L_f \) is a uniformly bounded operator in this context.

Throughout this and the next three sections, we will fix \( \lambda \) with \( 0 < \lambda < \frac{1}{6} \) and often omit it from the notation. All curves will be fibers of the universal \( G \)-twisted curve \( \overline{U}_{g,n} \), but we will suppress \( g \) and \( n \) from the notation. In Section 2, we fixed
a Riemannian metric on $\mathcal{T}_{g,n}$ and a defining function $\rho$ for the nodal set. For each $p \geq 2$ define a norm on sections of a vector bundle over a curve $C$ by

\[(5.1) \quad \|\eta\|_{p,\lambda}^p = \int_C \rho^{p-2-\lambda} |\eta|^p \, dvol_C.\]

The space $\text{Map}_\lambda(X)$ of Definition 2.1 carries two natural vector bundles $\mathcal{E}$ and $\mathcal{F}$; their fibers are described as follows.

- At a map $(C, f)$, let $E_f$ be the Banach space obtained as the completion of the space $E_f$ in (4.4) with respect to the norm

\[(5.2) \quad \|\xi\|_{1,p} = \|\nabla \xi\|_{2,\lambda} + \|\nabla \xi\|_{p,\lambda} + \left(\int_C |\xi|^p\right)^{\frac{1}{p}}.\]

- Similarly, let $F_f$ be the completion of the space $F_f$ in (4.4) with respect to the weighted $L^p$ norm

\[(5.3) \quad \|\|\eta\|\|_p = \|\eta\|_{2,\lambda} + \|\eta\|_{p,\lambda}.\]

On each component $B_i(\delta)$ of $B(\delta)$, we can choose coordinates and use the parameterizations (2.9) and (2.10) to rewrite each part of (5.2) as an integral over a cylinder $T(\delta)$. In particular, as in (2.12)

\[(5.4) \quad \int_{B_i(\delta)} \rho^{p-2-\lambda} |\nabla \xi|^p \approx \int_{T(\delta)} \rho^{-\lambda} |\nabla \xi|^p \quad \text{and} \quad \int_{B_i(\delta)} |\xi|^p \approx \int_{T(\delta)} \rho^{-2} |\xi|^p.\]

The first equivalence also holds when $\nabla \xi$ is replaced by any bundle-valued 1-form $\eta$.

On the other hand, on any $C(\delta) \subset C$ with $\delta > 0$, the function $\rho^{-\lambda}$ is bounded above and below by positive constants, so the norms (5.2) and (5.3) are equivalent to the standard unweighted $L^{1,p}$ and $L^p$ norms respectively. This is true, in particular, on any smooth domain $C$ (because then $C = C(\delta)$ for small $\delta$). However, the norms in these equivalences depend on $\delta$.

**Remark 5.1.** Our norms are closely related to those in [LT2], especially if one takes $\lambda = p - 2$ with $2 < p < 13/6$. They are chosen with two points in mind:

(i) When transferred to the cylinder by (5.4), the norm should include an exponential weight $\rho^{-\lambda} \approx e^{\lambda |t|}$ in order to obtain the Poincaré inequalities of Section 6. In terms of the original domain, this gives the awkward-looking weighting factor $\rho^{p-2-\lambda}$ in (2.5) and (5.2).

(ii) Weighted $L^p$ norms give decay estimates like Lemma 2.3 and (5.7) below, while weighted $L^2$ norms are well-adapted for integration by parts arguments, as we will see in Section 6. The sum of weighted $L^p$ and $L^2$ norms, as in (2.5), (5.2) and (5.3), has both advantages.
Definition 5.2. Fix \( p > 2 \), topologize the space
\[
\mathcal{E} = \{ (C, f, \xi) \mid (C, f) \in \text{Map}_\lambda(X), \xi \in \mathcal{E}_f \}
\]
by saying that a sequence \((C_n, f_n, \xi_n)\) converges to \((C, f, \xi)\) if
(a) \((C_n, f_n) \to (C, f)\) as in Definition 2.2,
(b) \(\|\xi_n\|_{1,p} \to \|\xi\|_{1,p}\),
(c) \(\xi_n \to \xi\) in the norm (5.2) on \(C(\delta)\) for every \(\delta > 0\) after identifying the domains by a trivialization (2.4).

The topological space \(\mathcal{F}\) is defined similarly, using triples \((C, f, \eta)\) with \(\eta \in \mathcal{F}_f\) and using the norm (5.3) instead of (5.2).

Corollary 5.5 below shows that the matching condition (4.4) is preserved under convergence in this topology. In preparation, we prove two lemmas about the Sobolev norms (5.2) and (5.3). Recall that in dimension 2, there is a Sobolev embedding \(L^{1,p} \subset L^\infty\) for \(p > 2\). For the weighted norm (5.2) there is a similar embedding with a constant that is uniform even as necks pinch to become nodes:

**Lemma 5.3.** For each \( p > 2 \) there is a constant \( c, \) depending on \( p \) but uniform for domains \( C \) in the universal curve and the map \( f \in \text{Map}_\lambda(X) \), such that
\[
\|\xi\|_\infty \leq c \|\xi\|_{1,p} \quad \text{for all } \xi \in \mathcal{E}_f.
\]

In particular, convergence in the norm (5.2) implies convergence in \(C^0\).

**Proof.** Set \( \delta = \frac{1}{4} \). Then each fiber \( C = C_z \) of the universal curve decomposes as \(C(\delta) \cup B(\delta)\) as in (2.2) (we include the case with \(B(\delta)\) empty and \(C(\delta) = C\)) and the diffeomorphisms (2.10) are defined on the \(4\delta\)-neighborhoods of the nodes. The domains \(C(\delta)\) have uniform geometry, so the norm of the Sobolev embedding \(L^{1,p} \subset L^\infty\) on \(C(\delta)\) is bounded independent of \(z\). This, and the fact that \(\frac{1}{4} \leq \rho \leq 2\) on \(C(\delta)\), implies that \(\|\xi\|_\infty \leq c(p) \left( \|d|\xi||_{p,\lambda} + \|\xi\|_p \right)\) on \(C(\delta)\). Also, on each component of \(B(2\delta)\), the proof of Lemma 2.3 shows that \(\text{osc } |\xi| \leq c\|d|\xi||_{p,\lambda}\). On both domains, we have \(\|d|\xi||_{p,\lambda} \leq c\|\nabla \xi\|_{p,\lambda}\) by “Kato’s inequality”: for each smooth section \(\xi\) and each connection \(\nabla\) compatible with the metric one has \(|d|\xi|| \leq |\nabla \xi|\) almost everywhere. The lemma follows because \(\|\xi\|_\infty\) is bounded by the sup of \(|\xi|\) on \(C(\delta)\) plus the oscillation of \(|\xi|\) on \(B(2\delta)\). \(\Box\)

The next result improves Lemma 5.3 by bounding the oscillation of \(\xi\)—not just \(|\xi|\)—in the necks \(B(\delta)\). This requires replacing Kato’s inequality with bounds on the connection. Recall from Section 2 that we have fixed an isometric embedding of \(X\) into \(\mathbb{R}^N\). Hence any \(\xi \in \Gamma(f^*TX)\) can be written as an \(\mathbb{R}^N\)-valued function \(\xi = (\xi^1, \ldots, \xi^N)\) on \(C\) and
\[
\nabla \xi = d\xi + (f^*A)\xi
\]
where $V$ is the pullback connection and $f^*A$ is the pullback of the second fundamental form, which satisfies $|f^*A| \leq |A| |df|$.

**Lemma 5.4.** For each $p > 2$ there are constants $c$ and $\delta_0$ and a neighborhood $N$ of the space of $J_\alpha$-holomorphic maps in the $\lambda$-topology such that for each $f : C \to ND$ in $N$

(a) the image $f(C)$ lies in the unit disk bundle $ND(1)$,

(b) for each $\delta < \delta_0$ the oscillation of each $\xi \in E_f$ on each component of $B(\delta)$ satisfies

$$\text{osc}_{B(\delta)} \xi \leq c \delta^{\lambda} \|\xi\|_{1,p}.$$  

**Proof.** By Lemma 1.1 the image of each $J_\alpha$-holomorphic map lies in $D$. Taking $\varepsilon = 1$ in Lemma 2.4 then shows that there is a neighborhood $N_1$ of the space of $J_\alpha$-holomorphic maps such that the images of all maps in $N_1$ lie in $ND(1)$.

Bounding the oscillation of each $\xi$ exactly as in Lemma 2.3, we have

$$\text{osc}_{B(\delta)} \xi \leq c \delta^{\lambda} \left( \int_T \rho^{-\lambda} |d\xi|^p \right)^{\frac{1}{p}}.$$  

We can use (5.6) to replace $d\xi$ by $\nabla \xi - A_f df \xi$. Part (a) above insures that the image of $f$ lies in $ND(1)$, and by compactness the second fundamental form $A$ is uniformly bounded on $ND(1)$. Also using Lemma 5.3, we therefore have

$$\|d\xi\|_{p,\lambda} \leq \|\nabla \xi\|_{p,\lambda} + c \|\xi\|_{\infty} \|df\|_{p,\lambda} \leq \left( 1 + c \sqrt{E_p(f)} \right) \|\xi\|_{1,p}$$

where $E_p$ is the $p$-energy (2.6). Finally, set $N = N_1 \cap \text{Map}^{2E}(ND)$ where $E$ is the constant in Theorem 2.5. Then $N$ is a neighborhood of the space of $J_\alpha$-holomorphic maps and each $f \in N$ satisfies $E_p(f) \leq 2E$. The lemma follows from the two displayed equations above. \qed

One consequence of Lemma 5.4 is that each $\xi \in E_f$ has a well-defined value $\xi(p_i)$ at each node $p_i$ of the normalization of $C$, and these values satisfy the matching condition in the definition (4.4) of $E_f$. This matching condition is not mentioned in Definition 5.2. The following corollary shows that the convergence in Definition 5.2 preserves the matching condition.

**Corollary 5.5.** If a sequence $\{(C_n, f_n, \xi_n)\}$ in $E$ converges in the sense of Definition 5.2 to a limit $(C, f, \xi)$, then the limit $(C, f, \xi)$ satisfies the matching condition (4.4), so lies in $E_f$.

**Proof.** As in (4.4), the limit $\xi$ is a section of the pullback of the bundle $N$ to the normalization $\tilde{C}$. Fix a node $n$ of $C$ and let $p$ and $q$ be the two points of $\tilde{C}$
corresponding to the node \( n \). By Lemma 5.4 for each \( \varepsilon > 0 \) we can fix a \( \delta > 0 \) such that
\[
\text{osc}_{D(p,\delta)} \xi \leq \varepsilon \quad \text{osc}_{D(q,\delta)} \xi \leq \varepsilon \quad \text{osc}_{B(\delta)} \xi_n \leq \varepsilon \quad \forall n
\]
where \( D(p,\delta) \) and \( D(q,\delta) \) are disks in \( \tilde{C} \) centered at \( p \) and \( q \). For this \( \delta \), we can identify \( C_n(\delta) \) with \( C(\delta) \) and then \( \xi_n \to \xi \) on \( C(\delta) \) as in Definition 5.2(c). Then \( \partial B(\delta) \) consists of two disjoint circles, one identified with \( \partial D(p,\delta) \) and the other with \( \partial D(q,\delta) \). Choose points \( x \in \partial D(p,\delta) \) and \( y \in \partial D(q,\delta) \). Then by (5.5)
\[
\left|\xi_n(x) - \xi(x)\right| \leq c \left\|\xi_n - \xi\right\|_{1,p} \leq \varepsilon
\]
for all large \( n \). The same inequality holds with \( x \) replaced by \( y \). Altogether, \( |\xi(p) - \xi(q)| \) is bounded by the sum of five terms
\[
\left|\xi(p) - \xi(x)\right| + \left|\xi(x) - \xi_n(x)\right| + \left|\xi_n(x) - \xi_n(y)\right| + \left|\xi_n(y) - \xi(y)\right| + \left|\xi(y) - \xi(q)\right|
\]
with each term bounded by \( \varepsilon \). Thus \( |\xi(p) - \xi(q)| \leq 5\varepsilon \) for all \( \varepsilon > 0 \), so the limit \( \xi \) satisfies the matching condition \( \xi(p) = \xi(q) \). \( \square \)

We next show that \( L_f \) is a bounded operator with the norms (5.2) and (5.3). For our purposes it is important to have bounds that are uniform for all maps \( f \) in some neighborhood of the space of \( J_\alpha \)-holomorphic maps.

**Proposition 5.6.** (Uniform boundedness of \( L_f \)) For each \( p > 2 \) there is a constant \( c = c(p) \) such that for each \( f : C \to N_D \) in the neighborhood \( N \) of Lemma 5.4 and each \( \xi \in E_f \)
\[
\left\| L_f \xi \right\|_p \leq c(1 + \sqrt{E}) \left\| \xi \right\|_{1,p}
\]
where \( E \) is the constant of Theorem 2.5.

**Proof.** From (4.3) we have the pointwise bound \( |L_f \xi| \leq |\nabla \xi| + |\nabla \alpha| \|\xi\| \|df\| \). By Lemma 5.4 the image of \( f \) lies in a compact set in \( N_D \) where \( |\nabla \alpha| < c_1 \) for some \( c_1 \). Integrating using norms (5.2) and (5.3) and definition (2.6), we have
\[
\left\| L_f \xi \right\|_p \leq \left\| \xi \right\|_{1,p} + c_1 \|\xi\|_\infty \sqrt{E(f)}
\]
with \( \|\xi\|_\infty \) bounded as in (5.5) and \( E(f) \leq 2E \) as at the end of the proof of Lemma 5.4. The proposition follows. \( \square \)

**6. Poincaré inequalities on weighted spaces.** For each \( J_\alpha \)-holomorphic map \( f : C \to N_D \), the modified linearization operator (4.5) is an elliptic operator whose kernel is 0 by Theorem 4.2. Consequently, there is a Poincaré inequality of the form \( \|\xi\| \leq c \|L_f \xi\| \) for a variety of norms. The constant \( c \) in this inequality need not be uniform in a family of maps whose domains pinch to a nodal curve.
For the weighted Sobolev norms introduced in Section 5, however, there is such an inequality with uniform constant. This will be proven in Theorem 7.7 based on the results in this section.

Because $L_f$ is the $\overline{\partial}$-operator plus lower order terms, the key step is establishing Poincaré inequalities for $\overline{\partial}$ on the cylinders that parameterize the thin part of the domain curves as described in Section 2. Thus we continue to use the norms (5.1)–(5.3), but now will work on the $T(\delta)$ side of (5.4) with the $p = 2$ norms. These cylinders are of two types: half-infinite cylinders, which parameterize neighborhoods of nodes of $C$, and finite cylinders that parameterize necks in a nearly-nodal domain $C$. In both cases we will consider complex-valued functions $\phi : T \to \mathbb{C}$ satisfying

$$
\|\partial \phi\|_{2,\lambda}^2 = \int_T \rho^{-\lambda} |\overline{\partial} \phi|^2 < \infty \quad \text{and} \quad \int_T |d\phi|^2 < \infty
$$

and seek Poincaré inequalities with constants independent of the length of the cylinder.

We begin by observing that if $\phi$ satisfies (6.1) then the weighted $L^2$ norm of $d\phi$ is finite. This is immediately true for smooth domains because $\rho^{-\lambda}$ is bounded on the domain. The following lemma shows that it is also true in the nodal case.

**Lemma 6.1.** (Nodes) Let $T = [0, \infty) \times S^1$ with coordinates $(t, \theta)$. If $\phi : T \to \mathbb{C}$ is a smooth function satisfying (6.1), then $\|d\phi\|_{2,\lambda} < \infty$ and for $0 < \lambda < \frac{1}{6}$

$$
\int_{T'} e^{\lambda t} |d\phi|^2 \leq 6 \int_T e^{\lambda t} |\overline{\partial} \phi|^2 + 3 \int_{E} e^{\lambda t} |d\phi|^2
$$

where $T' = [\frac{1}{2}, \infty) \times S^1$ and $E$ denotes the end $[0, \frac{1}{2}] \times S^1$.

**Proof.** Writing $\phi = u + iv$, we have

$$
|d\phi|^2 dt d\theta = 4|\overline{\partial} \phi|^2 dt d\theta + 2d(u dv).
$$

Multiplying by $e^{\lambda t}$ and noting that $d(e^{\lambda t} u dv) = e^{\lambda t} d(u dv) + \lambda e^{\lambda t} u v_t dt d\theta$ gives

$$
e^{\lambda t}|d\phi|^2 dt d\theta = 4e^{\lambda t}|\overline{\partial} \phi|^2 dt d\theta + 2d(e^{\lambda t} u dv) - \lambda e^{\lambda t} u v_t dt d\theta.
$$

Integrating over any circle $S_t = \{ t \} \times S^1$ and integrating by parts, one also sees that

$$
\int_{S_t} u v_t = \int_{S_t} \frac{i}{2} (\phi \overline{\phi}_\theta) \leq \frac{1}{2} \int_{S_t} |d\phi|^2
$$

(this last inequality can be checked by Fourier expansions). Fixing $s \geq 0$ and integrating over the annulus $A_{st} = [s, t] \times S^1 \subset T$ using the above equations and
Stokes’ Theorem then gives
\[
\int_{A_{st}} e^{\lambda t} |d\phi|^2 \leq 4 \int_T e^{\lambda t} |\nabla \phi|^2 + 2 \int_{S_t} e^{\lambda t} |d\phi|^2 + 2 \int_{S_s} e^{\lambda s} |d\phi|^2 + \frac{\lambda}{2} \int_{A_{st}} e^{\lambda t} |d\phi|^2.
\]
Setting
\[
(6.2) \quad \Phi(t) = \int_{A_{st}} e^{\lambda t} |d\phi|^2 - 6 \int_T e^{\lambda t} |\nabla \phi|^2 - 3 \int_{S_s} e^{\lambda s} |d\phi|^2,
\]
rearranging, and using the fact that \(0 < \lambda < \frac{1}{6}\), we obtain the inequality
\[
(6.3) \quad \Phi(t) \leq 3 \Phi'(t).
\]
Now suppose \(\Phi(t_0) > 0\) for some \(t_0 > s\). Then \(\Phi(t) > 0\) for all \(t > t_0\). Integrating (6.3) over the interval \([t, L]\) shows that
\[
\Phi(t) \leq e^{\frac{t-L}{\lambda}} E(L)
\]
for \(t_0 \leq t < L\). In particular,
\[
0 < \Phi(t_0) \leq c(t_0) e^{\frac{L}{\lambda}} \int_0^L e^{\lambda t} |d\phi|^2 \leq c(t_0) e^{(\lambda - \frac{1}{2})L} \|d\phi\|^2_2.
\]
Since \(\lambda < \frac{1}{6}\) we have a contradiction for large \(L\). Therefore, \(\Phi(t) \leq 0\) for all \(t\) and all \(s\). With this, the lemma follows by integrating both sides of (6.2) over the \(s\) variable from 0 to \(\frac{1}{2}\). \(\square\)

**Lemma 6.2.** (Nodes) For each smooth function \(\phi : T \to \mathbb{C}\) satisfying (6.1), there exists a unique constant \(\overline{\phi} \in \mathbb{C}\) such that the integrals over the sets \(T', T\) and \(E\) of Lemma 6.1 satisfy
\[
\int_{T'} \rho^{-\lambda} |\phi - \overline{\phi}|^2 \leq c(\lambda) \int_T \rho^{-\lambda} |\nabla \phi|^2 + 8 \int_E \rho^{-\lambda} |d\phi|^2
\]
where \(c(\lambda) = 4 + 8\lambda^{-2}\).

**Proof.** First define a function \(g(t)\) by averaging over circles \(S_t = \{t\} \times S^1\)
\[
(6.5) \quad g(t) = \frac{1}{2\pi} \int_{S_t} \phi.
\]
The oscillation of \(g(t)\) on \([L, \infty)\) can be estimated by using the fundamental theorem of calculus and applying Holder’s inequality to \(g' = \rho^{\lambda/2} \cdot \rho^{-\lambda/2} g'\):
\[
\text{osc}_{[L, \infty)} g \leq \int_L^\infty |g'| \leq \left( \int_L^\infty e^{-\lambda t} dt \right)^{\frac{1}{2}} \left( \int_L^\infty \rho^{-\lambda} |g'|^2 dt \right)^{\frac{1}{2}} \leq \frac{1}{\sqrt{\lambda}} e^{-\frac{L}{\lambda}} \|d\phi\|^2_{2, \lambda; [L, \infty)}
\]
(6.6)
(observe that \(\|d\phi\|_{2,\lambda}\) is finite by Lemma 6.1). It follows that \(g(t)\) approaches a constant \(\bar{\phi} \in \mathbb{C}\) as \(t \to \infty\), and \(|g(t) - \bar{\phi}|\) is bounded for \(t \geq L\) by the right-hand side of (6.6). Writing \(\lambda e^{\lambda t} dt = d(e^{\lambda t})\) and integrating by parts gives

\[
\lambda \int_0^L e^{\lambda t} |g - \bar{\phi}|^2 dt \leq e^{\lambda L} |g - \bar{\phi}|^2 \bigg|_0^L + \int_0^L e^{\lambda t} (\varepsilon |g - \bar{\phi}|^2 + \varepsilon^{-1} |g'|^2) dt
\]

for any \(\varepsilon > 0\). The lower boundary term is negative, so can be dropped. The upper boundary term is dominated by \(e^{\lambda L}\) times the square of the right-hand side of (6.6), so vanishes in the limit \(L \to \infty\). Taking \(\varepsilon = \frac{1}{2\lambda}\) and rearranging gives

\[
(6.7) \quad \int_0^\infty e^{\lambda t} |g - \bar{\phi}|^2 dt \leq 4\lambda^{-2} \int_0^\infty e^{\lambda t} |g'|^2 dt.
\]

Next, write the Fourier expansion of \(\phi\) in the form

\[
(6.8) \quad \phi(t, \theta) - \bar{\phi} = f(t) + \sum_{n \neq 0} a_n(t) e^{in\theta}
\]

with \(f(t) = g(t) - \bar{\phi}\). Integrating over the circles \(S_t\), we have

\[
(6.9) \quad \frac{1}{2\pi} \int_{S_t} |\phi - \bar{\phi}|^2 = |f(t)|^2 + \sum_{n \neq 0} |a_n(t)|^2
\]

and

\[
(6.10) \quad \frac{1}{\pi} \int_{S_t} |\bar{\phi}|^2 = |f'|^2 + \sum_{n \neq 0} |b_n(t)|^2 \quad \text{where} \quad b_n = a'_n - na_n.
\]

Let \(\beta = \beta_L(t)\) be a smooth positive cutoff function equal to 1 on \([\frac{1}{2}, L]\), with support in \([0, L + \frac{1}{2}]\) and satisfying \(\beta \leq 1\) and \(|d\beta| \leq 4\). Integrating \(\beta e^{\lambda t} |b_n|^2\) by parts and observing that \(|b_n|^2 \geq -n(|a_n|^2)' + n^2|a_n|^2\) yields

\[
\int_0^\infty \beta e^{\lambda t} \sum_{n \neq 0} |b_n|^2 \geq \frac{1}{2} \int_0^\infty \beta e^{\lambda t} \sum_{n \neq 0} |a_n|^2 - \frac{4}{2\pi} \int_{E \cup T_L} e^{\lambda t} |d\phi|^2,
\]

where \(T_L = [L, \infty) \times S^1\) and where we have used the inequalities \(n^2 - |n|\lambda \geq \frac{1}{2}\) and \(n|a_n|^2 \leq n^2|a_n|^2\) for \(n \neq 0\). Now take \(L \to \infty\). Because \(\|d\phi\|_{2,\lambda}\) is finite by Lemma 6.1, the part of the last integral over \(T_L\) vanishes in the limit, leaving

\[
2\pi \int_{\frac{1}{2}}^\infty e^{\lambda t} \sum_{n \neq 0} |a_n|^2 \leq 4\pi \int_0^\infty e^{\lambda t} \sum_{n \neq 0} |b_n(t)|^2 + 8 \int_E e^{\lambda t} |d\phi|^2.
\]

On the other hand, multiplying (6.9) by \(e^{\lambda t}\), integrating over \(t\), and using (6.7) gives

\[
\int_T e^{\lambda t} |\phi - \bar{\phi}|^2 \leq \frac{8\pi}{\lambda^2} \int_0^\infty e^{\lambda t} |f'(t)|^2 + 2\pi \int_{\frac{1}{2}}^\infty e^{\lambda t} \sum_{n \neq 0} |a_n|^2.
\]
The desired inequality (6.4) follows by combining the last two displayed equations and observing that each term on the right-hand side of (6.10) is less than the left-hand side of (6.10).

Finally, to prove the uniqueness of \( \overline{\phi} \), suppose that (6.4) holds for two constants \( \overline{\phi}_1 \) and \( \overline{\phi}_2 \). Then by the triangle inequality

\[
\int_0^L \int_0^{2\pi} e^{\lambda t} |\overline{\phi}_1 - \overline{\phi}_2|^2 = 2\pi \lambda^{-1} \left( e^{\lambda L} - 1 \right) |\overline{\phi}_1 - \overline{\phi}_2|^2
\]

is bounded, uniformly in \( L \). Taking \( L \to \infty \) then shows that \( \overline{\phi}_1 = \overline{\phi}_2 \). \( \square \)

**Lemma 6.3.** (Necks) Let \( T = [-L, L] \times S^1 \) with coordinates \( (t, \theta) \) and \( \rho^2 = 2|\mu| \cosh(2t) \). Then for each smooth function \( \phi : T \to \mathbb{C} \), there exists a constant \( \overline{\phi} \in \mathbb{C} \) such that

\[
\int_{T'} \rho^{-\lambda} |\phi - \overline{\phi}|^2 \leq c(\lambda) \int_{T'} \rho^{-\lambda} |\partial_t \phi|^2 + 8 \int_E \rho^{-\lambda} |d\phi|^2
\]

where \( T' = [-L + \frac{1}{2}, L - \frac{1}{2}] \times S^1 \), \( E \) is the end \( E = T \setminus T' \) and \( c(\lambda) = 4 + 16\lambda^{-2} \).

**Proof.** Define \( \overline{\phi} \in \mathbb{C} \) be the average value of \( \phi \) over the center circle \( S_0 = \{0\} \times S^1 \):

\[
\overline{\phi} = \frac{1}{2\pi} \int_{S_0} \phi.
\]

Then \( \phi - \overline{\phi} \) has the Fourier expansion (6.8) with \( f(0) = 0 \). For \( t \geq 0 \) write \( \rho^{-\lambda} = \sigma' \) on \([-L, L]\) where \( \sigma(t) = -\int_t^L \rho^{-\lambda}(r) dr \). Integrating by parts, we obtain

\[
\int_0^L \rho^{-\lambda} |f|^2 dt = \sigma |f|^2 \bigg|_0^L - \int_0^L \sigma 2 \text{Re} \overline{f} df \leq 0 + \int_0^L |\sigma| (|f|^2 + \varepsilon^{-1} |f'|^2) dt
\]

for any \( \varepsilon > 0 \). Because \( \rho^2 \leq 2|\mu| e^{2t} \leq 2\rho^2 \) we also have \( |\sigma| \leq 2\rho^{-\lambda} / \lambda \). After again taking \( \varepsilon = \frac{1}{4} \lambda \) and rearranging, we are left with the inequality

\[
\int_0^L \rho^{-\lambda} |f|^2 dt \leq 16\lambda^{-2} \int_0^L \rho^{-\lambda} |f'|^2 dt.
\]

Because \( \rho \) is an even function, (6.13) also holds on the interval \([-L, 0]\) and hence on \([L, L]\).

Now repeat the end of the proof of Lemma 6.2. Integrating the Fourier expansion (6.8) over the circles \( S_t \) again gives (6.9) and (6.10). This time, relate \( f \) and \( f' \) by (6.13) and choose a smooth positive cutoff function \( \beta \) that is equal to 1 on \([-L + \frac{1}{2}, L - \frac{1}{2}]\), with support in \([-L, L]\) and satisfying \( \beta \leq 1 \) and \( |d\beta| \leq 4 \). Multiply the term linear in \( n \) by \( \beta \rho^{-\lambda} \), integrate over \( t \), and integrate by parts, noting that \( |d \log \rho| = |\tanh(2t)| \leq 1 \) from (2.11). The lemma follows. \( \square \)
Remark. While the constant $\phi$ in Lemma 6.3 is not unique, the end of the proof of Lemma 6.2 shows that the range of possibilities for $\phi$ shrinks exponentially as the neck $T$ becomes longer.

Together, Lemmas 6.2 and 6.3 give a Poincaré inequality for functions on the thin part $B(\delta)$ of a curve $C$. As in Section 2, each component of the thin part is parameterized by a set $T(\delta)$ that is either a finite cylinder or two half-infinite cylinders. In both cases we use the weighted norm (2.12) on functions.

**PROPOSITION 6.4.** There is a constant $\delta_0$ such that for each $\delta < \delta_0$ and each $L^1_\text{loc}$ function $\phi : T(2\delta) \to \mathbb{C}$ satisfying (6.1), there exists a $\varphi \in \mathbb{C}$ with

$$
\int_{T(\delta)} \rho^{-\lambda} |\phi - \varphi|^2 \leq 32 \lambda^{-2} \int_{T(2\delta)} \rho^{-\lambda} |\partial \phi|^2 + 8 \int_{B(2\delta) \setminus B(\delta)} \rho^{-\lambda} |d\phi|^2.
$$

(6.14)

**Proof.** In the chart (2.8), the metric and the distance function on $B(\delta)$ induced by the metric on the universal curve are, for small $\delta$, uniformly close to the metric and the distance function induced on the curve $xy = \mu$ by the Euclidean metric on $\mathbb{C}^2$. Thus it suffices to show (6.14) for the Euclidean metric, taking $\rho^2$ to be $|x|^2 + |y|^2$. Because smooth functions are dense in $L^{1,2}$ it also suffices to assume that $\phi$ is smooth.

Each component of $B(2\delta)$ corresponds, under the parameterization $\phi$ of (2.9) or (2.10), to a cylinder $T(2\delta)$ isometric to either the cylinder $T$ in Lemma 6.2 or the $T$ in Lemma 6.3. In both cases, the image $\phi(E)$ lies in the annulus $B(2\delta) \setminus B(\delta)$ (note $\sqrt{e} < 2$). Thus (6.14) follows from Lemmas 6.2 and 6.3.  

**7. Estimates on the linearization $L_f$.** This section contains the essential elliptic estimates for the modified linearization operator $L_f$ defined by (4.3). Such estimates are standard for unweighted Sobolev spaces, but we need them for the weighted spaces $\mathcal{E}_f$ and $\mathcal{F}_f$, and we need them to be locally uniform on the space of maps $\text{Map}_\lambda(X)$ of Definition 2.2. Care is needed because on weighted Sobolev spaces the Rellich compactness lemma may fail and because elliptic operators need not be Fredholm (cf. [L]).

**7.1. The interior estimate.** The first step is to parlay the Poincaré inequality (6.14) into an estimate on the thin region $B(\delta)$. This step is possible only because we are working with weighted norms.

**LEMMA 7.1.** (Interior estimate) Fix $p > 2$ and a $J_\alpha$-holomorphic map $f$. Then there is a neighborhood $\mathcal{N}_f$ of $f$ in $\text{Map}_\lambda(N_D)$ and constants $\delta_1$, $c_1$ and $c_2 = c_2(\delta)$ such that if $g \in \mathcal{N}_f$, $\delta < \delta_1$, $\xi \in L^{1,p}$ and $L_g \xi \in \mathcal{F}_g$, then $\xi \in \mathcal{E}_g$ and

$$
\|\xi\|_{1,p;B(\delta)} \leq c_1 \|L_g \xi\|_{p;B(4\delta)} + c_2 \|\xi\|_{1,p;B(4\delta) \setminus B(\delta)}.
$$

(7.1)
Proof. By Lemma 1.1 the image of $f$ lies in the set where $\alpha = 0$, and by Lemma 2.3 we can choose $N_f$ and $\delta$ small enough that the image of each component of $B(4\delta)$ lies in a holomorphic coordinate chart for the bundle $N \to N_D$. In such a chart, we can regard $g \in N_f$ and any $\xi \in \mathcal{E}_g$ as complex-valued functions on $B(2\delta)$ or, equivalently, on $T(2\delta)$ via (2.9) and (2.10). To obtain uniform estimates, we will work on $T(2\delta)$, and return to $B(2\delta)$ at the end of the proof.

Using formula (4.3) we can write $L_g$ as the standard $\overline{\partial}$-operator on functions plus additional terms:

$$L_g \xi = \overline{\partial} \xi + (A_g \xi)^{0,1}$$

where $A_g$ has the form $A_g \xi = g^* \Gamma \xi + \nabla \xi K_\alpha \circ dg \circ j$.

Here $j$ is the complex structure on $C$, $\Gamma$ is a term built from the Christoffel symbols satisfying $|g^* \Gamma| \leq c_3 \text{diam}(f(B(\delta))) |dg| \leq c_4 |dg|$, $|\nabla K_\alpha \circ dg| \leq c_5 |dg|$. Similarly, $\nabla \xi = d\xi + \Gamma \xi$ with the same bounds on $\Gamma$. Hence

$$||L_g \xi| - |\overline{\partial} \xi|| + ||\nabla \xi| - |d\xi|| \leq c_6 |dg| |\xi|.$$  \hspace{1cm} (7.2)

By the definition of $\text{Map}_{\lambda}(N_D)$, the weighted $p$-norm $\||dg||_p$ is finite. Furthermore, $|\xi|$ is bounded because of the hypothesis $\xi \in L^{1,p}$ and the Sobolev embedding $L^{1,p} \subset C^0$. These facts ensure that both the operator $A_g$ in (7.2) and the right-hand side of (7.3) are in $\mathcal{F}_g$. We then see that both conditions in equation (6.1) hold:

- Using the hypothesis $L_g \xi \in \mathcal{F}_g$, (7.3) implies that $\overline{\partial} \xi \in \mathcal{F}_g$.
- By the hypothesis $\xi \in L^{1,p}$, the $L^2$ norm of $\nabla \xi$ on $B(\delta)$ is finite. But then $\nabla \xi \in L^2(T(\delta))$ (take $p = 2$ and $\lambda = 0$ in (5.4)), and hence (7.3) shows that $d\xi \in L^2(T(\delta))$.

Thus the lemmas of Section 6 apply to $\xi$.

Now restrict attention to one component of $B(\delta)$ and set $\zeta = \xi - \overline{\xi}$ where $\overline{\xi} \in \mathbb{C}$ is the constant provided by Proposition 6.4. For each integer $n$ let $A(n) \subset T$ be the annulus with $n \leq t \leq n + 1$ and let $A^+(n)$ be the annulus with $n - 1 \leq t \leq n + 2$. Since $\zeta \in L^{1,p}$ on $A(n)$, standard elliptic theory (Lemma 1.2.2 of [IS1] or Lemma C.2.1 of [MS] and interpolation) shows that

$$||\zeta||_{1,p;A(n)} \leq c_7 \left(||\overline{\partial} \zeta||_{p;A^+(n)} + ||\zeta||_{2;A^+(n)}\right)$$  \hspace{1cm} (7.4)

where these are unweighted $L^p$ norms. The constant $c_7$ is independent of $n$ because the $A^+(n)$ are isometric to one another. Holder’s inequality shows that (7.4) also holds when the $p$ on the left side is replaced by 2 (retaining the $p$ on the right side).

Recall from (2.11) that $p$ is equal to $e^{-t}$ on the half-infinite cylinders and satisfies $|\mu| e^{2|t|} \leq p^2 \leq 2|\mu| e^{2|t|}$ on the finite cylinders. In both cases, the ratio of the maximum to the minimum value of $p^{-\lambda}$ across $A^+(n)$ is bounded uniformly in $n$. Therefore (7.4) remains valid (with a modified constant) when the norms are weighted by $p^{-\lambda}$; taking the $p$-power of both sides gives the factor of $\delta$ below. Note that the union of the $A^+(n)$ lies in $T(2\delta)$ and that each point on $T(\delta)$ lies in
three of the $A^+(n)$. Summing (7.4) on $n$ and using the inequality $\rho \leq 2\delta$ on $T(\delta)$, one therefore obtains

$$
\int_{T(\delta)} \rho^{-\lambda} |d\zeta|^p \leq c_8 \int_{T(\delta)} \rho^{-\lambda} |\overline{\partial}\zeta|^p + c_8 (2\delta)^{\frac{p+2}{p}} \left( \int_{T(\delta)} \rho^{-\lambda} |\zeta|^2 \right)^{\frac{p}{2}}.
$$

Here we have used the fact that $\overline{\partial}\zeta = \overline{\partial}\xi \in \mathcal{F}_g$ which, by Lemma 6.2, insures that the two integrals on the right-hand side—and therefore all three integrals—are finite. It also insures that the $|\zeta|^2$ term is bounded as in the Poincaré inequality (6.14) on $T(4\delta)$. Consequently,

$$
\|d\zeta\|_{p,\lambda;T(\delta)} \leq c_9 \left( \|\overline{\partial}\zeta\|_{p,\lambda;T(4\delta)} + \|\overline{\partial}\zeta\|_{2,\lambda;T(4\delta)} + \|d\zeta\|_{2,\lambda;T(4\delta)/T(\delta)} \right).
$$

But $\zeta = \xi - \overline{\xi}$ satisfies $d\zeta = d\xi$ and $\overline{\partial}\zeta = \overline{\partial}\xi$. After applying (7.3) we obtain

$$
\|\nabla\xi\|_{p,\lambda;T(\delta)} \leq c_{10} \left( \|L_g\xi\|_{p,T} + \|L_g\xi\|_{2,\lambda,T} + \|dg\xi\|_{p,\lambda;T} 
\quad + \|dg\xi\|_{2,\lambda,T} + \|\nabla\xi\|_{2,\lambda;T(\delta)} \right)
$$

where $T$ denotes $T(4\delta)$. This inequality holds in particular for $p = 2$. Adding the $p$ and $p = 2$ cases yields

$$
(7.5) \quad \|\nabla\xi\|_{p;T(\delta)} \leq c_{11} \left( \|L_g\xi\|_{p;T} + \|\xi\|_{\infty;T} \|dg\|_{p;T} \right) + c_{12} \|\xi\|_{1,p;T(\delta)}.
$$

Now Lemmas 7.2 and 7.3 below show that there is a constant $c_{13}$, independent of $\delta$, such that

$$
\|\xi\|_{\infty,T} \|dg\|_{p,T} \leq c_{13} \left( \delta^{\frac{\lambda}{p}} \|\nabla\xi\|_{p;T(\delta)} + \delta^{\frac{\lambda}{p}} \|\xi\|_{1,p;T(\delta)} \right) \cdot \delta^{\frac{1}{2} - \frac{\lambda}{2}}.
$$

Hence after taking $\delta$ sufficiently small, the middle term on the right-hand side of (7.5) can be absorbed partly on the other side of the equation and partly into the last term in (7.5). Returning to $B(\delta)$ and noting the equivalence at the beginning of the proof of Proposition 6.4, we then have

$$
(7.6) \quad \|\nabla\xi\|_{p;B(\delta)} \leq c_{14} \|L_g\xi\|_{p;B(4\delta)} + c_{15}(\delta) \|\xi\|_{1,p;B(4\delta)\setminus B(\delta)}.
$$

Finally, the last term in the norm (5.2) on $B(\delta)$ can be bounded using (7.7) below:

$$
\left( \int_{B(\delta)} |\xi|^p \right)^{\frac{1}{p}} \leq \left[ \text{Area}(B(\delta)) \right]^{\frac{p}{2}} \|\xi\|_{\infty} \leq c_{16} \delta^{\frac{\lambda}{2}} \left( \|\nabla\xi\|_{p;B(\delta)} + \|\xi\|_{1,p;B(4\delta)\setminus B(\delta)} \right).
$$

The inequality of the lemma follows by combining this with (7.6) and taking $\delta$ sufficiently small. Since we have shown these integrals are finite, we also conclude that $\xi \in \mathcal{E}_g$. □

The above proof made use of the following two technical lemmas.
Lemma 7.2. Fix \( p > 2 \). There is a constant \( c = c(p) \), independent of \( \delta \leq 1 \), such that for each \( g : T(4\delta) \to X \) with finite \( p \)-energy, each \( \xi \in \mathcal{E}_g \) satisfies

\[
\|\xi\|_{\infty,T(4\delta)} \leq c \left( \delta^\frac{1}{p} \|\nabla\xi\|_{p,T(\delta)} + \delta^{-\frac{2}{p}} \|\xi\|_{1,p,T(4\delta)\setminus T(\delta)} \right).
\]

Proof. As in Lemmas 6.1 and 6.3, let \( E \) be the end of \( T = T(4\delta) \) isometric to one or two copies of \([0, \frac{1}{2}] \times S^1\). We can bound the oscillation of \( |\xi| \) as in the proofs of Lemmas 2.3 and 5.3, and bound \( |\xi| \) on \( E \) using the Sobolev embedding \( L^1,p \subset L^\infty \):

\[
\|\xi\|_{\infty,T} \leq (\text{osc}_T |\xi|)^p + \|\xi\|_{\infty,E}^p \leq c_1 \delta^\lambda \|\nabla\xi\|_{p,T} + \int_E |d\xi|^p + |\xi|^p.
\]

But \( |d\xi|^p \leq \delta^\lambda p^{-\lambda} |\nabla\xi|^p \) by Kato’s inequality, so we obtain

\[
\|\xi\|_{\infty,T}^p \leq c_1 \delta^\lambda \left( \|\nabla\xi\|_{p,T(\delta)}^p + \|\nabla\xi\|_{p,T(\delta)}^p \right) + \delta^\lambda \int_E \rho^{-\lambda} |\nabla\xi|^p + \delta^{-2} \int_E \rho^2 |\xi|^p.
\]

Translating the norm (5.2) to \( T \) using (5.4), one sees that this gives (7.7) for \( \delta \leq 1 \) because \( E \subset T(4\delta) \setminus T(\delta) \) under the transformations (2.9) and (2.10).

Lemma 7.3. Fix \( p > 2 \) and a \( J_\alpha \)-holomorphic map \( f \). There are positive constants \( \delta_0 \) and \( c \) such that for each \( \delta < \delta_0 \) there is a neighborhood \( \mathcal{N}_f(\delta) \) of \( f \) such that, for each \( (C, g) \in \mathcal{N}_f(\delta) \), the function \( |dg| \) satisfies \( \|dg\|_p \leq c \delta^{\frac{1}{2} - \frac{\lambda}{2}} \) on \( B(\delta) \subset C \).

Proof. The energy bound (2.15) on the \( J_\alpha \)-holomorphic map \( f \) shows that \( \|df\|_{p,B_0(\delta)} \leq c_1 \delta^{\frac{1}{2} - \frac{\lambda}{2}} \) where \( B_0(\delta) \) is the thin part of the domain \( C_0 \) of \( f \). Also, by the triangle inequality,

\[
\|dg\|_{p,B(\delta)} \leq \|df\|_{p,B_0(\delta)} + \left| \sqrt{E_p(g,\delta)} - \sqrt{E_p(f,\delta)} \right|
\]

(7.8)

where \( E_p(g,\delta) \) is the \( p \)-energy integral (2.6) on the thin part \( B(\delta) \) of the domain \( C \) of \( g \). The last two terms in (7.8) vanish as \( g \to f \) in the \( \lambda \)-topology because, by parts (b) and (c) of Definition 2.2,

\[
E_2(g,\delta) = E_2(g) - \|dg\|_{2,\lambda,C_0(\delta)}^2 \to E_2(f) - \|df\|_{2,\lambda,C_0(\delta)}^2 = E_2(f,\delta).
\]

One similarly sees that \( E_p(g,\delta) \to E_p(f,\delta) \). Thus \( \|dg\|_p \leq c \delta^{\frac{1}{2} - \frac{\lambda}{2}} \) whenever \( g \) is close to \( f \).
7.2. The exterior estimate. For a fixed map \( f : C \to N_D \), standard theory gives a elliptic estimate on the thick part \( C(\delta) \) of the form

\[
\|\xi\|_{1,p,C(2\delta)} \leq c \left( \|L_f \xi\|_{p,C(\delta)} + \|\xi\|_{p,C(\delta)} \right)
\]

(7.9)

where these are unweighted \( L^{1,p} \) and \( L^p \) norms. The next lemma shows that the corresponding inequality holds for the weighted norms, uniformly for maps near \( f \). In fact, because the weighting function \( \rho \) is bounded above and below on \( C(\delta) \), the extension to weighted norms, with a constant depending on \( \delta \), is immediate. The issue, then, is whether the weighted version of (7.9) holds with a constant that is locally constant on the space of maps with the \( \lambda \)-topology of Definition 2.2.

**Lemma 7.4.** (Uniform exterior estimate) Fix \( p > 2 \) and a \( J_\alpha \)-holomorphic map \( (C_0,f) \). Then for each \( \delta, 0 < \delta < 1 \), and each \( \epsilon > 0 \), there is a neighborhood \( N_f \) of \( f \) in \( \text{Map}_\lambda(N_D) \) and a constant \( c = c(p, \delta) \) such that for all \( g \in N_f \), each \( \xi \in L^{1,p}(C(\delta)) \) satisfies

\[
\|\xi\|_{1,p,C(2\delta)} \leq c \left( \|L_g \xi\|_{1,p,C(\delta)} + \|\xi\|_{1,p,C(\delta)} \right) + \epsilon \|\xi\|_{1,p,C(\delta)}.
\]

(7.10)

**Proof.** First, by Definition 2.2(a), there is a neighborhood \( N_f \subset N \) so that the domains of all maps \( (C,g) \) in \( N_f \) lie in a single chart in the universal curve of the form (2.3) or (2.4). This chart gives an identification \( C(\delta) = C_0(\delta) \) that is \( C^1 \) close to an isometry. We can regard each map \( g : C(\delta) \to N_D \) in \( N_f \) as a map \( g : C_0(\delta) \to N_D \); by the proof of Lemma 2.4 these satisfy

\[
\sup_{x \in C_0(\delta)} \text{dist}(f(x),g(x)) \leq c_1 \|f - g\|_{1,p,C_0(\delta)}.
\]

(7.11)

Recall that the \( J_\alpha \)-holomorphic map \( f \) is smooth and, by Lemma 1.1, has image in the zero section \( D \) of \( N_D \). Thus (7.11) implies that the images of all \( g \in N_f \) lie in a neighborhood of the zero section where there is a uniform bound on \( |\nabla K_\alpha| \).

Now fix \( x \in C_0(2\delta) \) and choose a disk \( D(x,2r) \subset C_0(\delta) \). From Definition 4.1, the operator \( L_f \) has the form \( L_f = \bar{\partial} + R_\alpha \) where \( |R_\alpha| \leq 2|\nabla K_\alpha||df| \) is bounded. Thus \( R_\alpha \in L^p \). Elliptic theory for such operators, as in [MS, Appendix C.2], yields an estimate

\[
\|\xi\|_{1,p,D(x,r)} \leq c_3 \left( \|L_f \xi\|_{p,D(x,2r)} + \|\xi\|_{p,D(x,2r)} \right)
\]

with \( c_3 \) depending on \( (C_0,f) \) and \( r \). We can add \( \|\xi\|_{1,2,D(x,r)} \) to the left-hand side by Holder’s inequality. We can also insert the weighting function \( \rho \) into each of the integrals, noting that \( \delta \leq \rho \leq 2 \) on \( D(x,2r) \subset C(\delta) \). The result is

\[
\|\xi\|_{1,p,D(x,r)} \leq c_4 \left( \|L_f \xi\|_{p,D(x,2r)} + \|\xi\|_{p,D(x,2r)} \right)
\]

(7.12)

for all \( \xi \in E_f \).
We next estimate \(|L_{f} - L_{g}|\), first on a small disk, then on \(C(2\delta)\). Fix \(x \in C(2\delta)\). After making \(r\) smaller, we may assume that \(f(D(x,2r))\) lies in a holomorphic coordinate chart \(U \subset ND\) with coordinates \(\{x^{i}\}\). In this chart, \(J\) is constant. In light of (7.11) there is a neighborhood \(N_{f}(x)\) of \(f\) such that the images \(g(D(x,2r))\) for all \(g \in N_{f}(x)\) lie in \(U\). As in the proof of Lemma 7.1 we can then regard \(g \in N_{f}(x)\) and any \(\xi \in E_{g}\) as complex-valued functions on \(D(x,2r)\). Since the \(J_{\alpha}\)-holomorphic map \(f\) has its image in \(D\), we can further assume that the images of \(g\) for all \(g \in N_{f}(x)\) lies in the \(\frac{1}{\delta}\)-neighborhood of the \(D\) in \(ND\).

As in (7.2), write \(L_{g}\) as the standard \(\overline{\partial}\)-operator on functions plus additional terms:

\[
(7.13) \quad L_{g}\xi = \overline{\partial}_{C}\xi + \pi_{C,g}^{0,1}(g^{*}\Gamma\xi + \nabla_{\xi}K_{\alpha}dgj)
\]

where \(\overline{\partial}_{C}\xi = \frac{1}{2}(d\xi + Jd\xi j)\) and the projection onto \(g^{*}N\)-valued \((0,1)\) forms is defined in terms of the complex structure \(j\) on \(C\) by

\[
\pi_{C,g}^{0,1}(\eta)(v) = \frac{1}{2}\left(\eta(v) + J\eta(jv)\right).
\]

Let \(j_{0}\) be the complex structure on \(C_{0}\). Note that (i) we may assume \(|j|\) is bounded on \(C_{0}(\delta)\) by making \(N_{f}\) smaller since \(|j_{0}| = 1\) on \(C_{0}\) and (ii) the smooth quantities \(\Gamma, J\) and \(\nabla K_{\alpha}\) are bounded. Thus (7.3) and (7.13) give the pointwise inequality:

\[
(7.14) \quad |(L_{g} - L_{f})\xi| \leq c_{5}\left(|f - g| + |df - dg| + |j - j_{0}|\right) ||\xi||_{\infty} + |j_{0} - j||\nabla\xi|
\]

where \(c_{5}\) depends only on \((C_{0}, f)\) and \(\delta\).

Now, fix \(\varepsilon > 0\). After making \(N_{f}\) smaller, we may assume that

\[
||j_{0} - j||_{\infty,C_{0}(\delta)} + ||f - g||_{C_{0}(\delta)} < \varepsilon
\]

for all \(g \in N_{f}(x)\) (cf. Definition 2.2). Consequently, (7.14) and Lemma 5.3 give

\[
(7.15) \quad |||(L_{g} - L_{f})\xi|||_{p;D(x,2r)} \leq c_{7}\varepsilon \||||\xi|||_{1,p;D(x,2r)}.
\]

Combining (7.12) and (7.15) then yields

\[
(7.16) \quad ||\xi||_{1,p;D(x,r)} \leq c_{8}\left(||L_{g}\xi||_{p;D(x,2r)} + ||\xi||_{p;D(x,2r)} + \varepsilon \||||\xi|||_{1,p;D(x,2r)}\right)
\]

for all \(g \in N_{f}(x)\). Finally, the compact curve \(C(\delta)\) is covered by disks \(D = D(x,2r)\) on which (7.16) holds. Let \(2r_{0}\) be the Lebesgue number of this cover. Then (7.16) holds on each disk with center in \(C(2\delta)\) and radius less than \(2r_{0}\). Choose a finite cover of \(C(2\delta)\) by such disks \(D(x_{i},2r_{0})\) so that each point of \(C(\delta)\) lies in at most 20 disks. Summing the integrals in the estimate (7.16) and intersecting the corresponding neighborhoods \(N_{f}(x_{i})\), one sees that (7.16) holds with \(D(x,r)\) replaced by \(C(2\delta)\) and \(D(x,2r)\) replaced by \(C(\delta)\), as required. \(\square\)
7.3. Global Poincaré inequalities. We can now combine the interior and exterior estimates to obtain a global Poincaré inequality. We do this first for a fixed $J_{\alpha}$-holomorphic map $f$, and then use the Compactness Theorem 2.5 to obtain a Poincaré equality valid for all maps in a neighborhood of the moduli space.

**Proposition 7.5.** Fix $p > 2$ and a $J_{\alpha}$-holomorphic map $(C, f)$. Then there is a neighborhood $N_f$ of $(C, f)$ in $\text{Map}_{\chi}(N_D)$ and a constant $c = c(p, f)$ such that the following holds: for each $(C', g) \in N_f$, every section $\xi$ of $g^*N$ with (i) finite (unweighted) $L^{1,p}$ norm and (ii) $L_g \xi \in \mathcal{F}_g$, satisfies $\xi \in \mathcal{E}_g$ and

\begin{equation}
|||\xi|||_{1,p} \leq c \|||L_g \xi|||_p.
\end{equation}

**Proof.** If this statement is false, there is a sequence of maps $(C_n, g_n) \to (C, f)$ and $\xi_n \in L^{1,p}(g_n^*N)$ with $|||\xi_n|||_{1,p} = 1$ for all $n$ and $|||L_{g_n} \xi_n|||_p \to 0$. Fix $\delta > 0$. As in the proof of Lemma 7.10, we can identify each $C_n(\delta)$ with $C(\delta)$. Under this identification the complex structures on $C_n(\delta)$ converge in $C^1$ to that of $C(\delta)$ as $n \to \infty$ and the norms (5.2) and (5.3) are uniformly equivalent to the standard Sobolev $L^{1,p} \cap L^{1,2}$ and $L^p \cap L^2$ norms.

By the compactness of the Sobolev embedding $L^{1,p} \subset C^0$ there is a subsequence, still denoted $\{\xi_n\}$, that converges weakly in $L^{1,p}$ and strongly in $C^0$ to some $\xi_0 \in \mathcal{E}_{f|C(\delta)}$. Hence $L_f \xi_0 = 0$. After replacing $\delta$ by $\delta/2$, then $\delta/4$, etc., repeatedly taking subsequences, and passing to a diagonal subsequence we obtain a continuous solution of $L_f \xi_0 = 0$ on $C \setminus \{\text{nodes}\}$, and this $\xi_0$ is bounded because the numbers $|||\xi_n|||_\infty$ are uniformly bounded by our hypothesis and Lemma 5.3. Lemma 7.6 below then shows that $\xi_0$ extends across the nodes to a smooth global solution of $L_f \xi_0 = 0$ on $C_0$. But $\ker L_f = 0$ by Vanishing Theorem 4.2, so in fact $\xi_0 = 0$. Thus $\xi_n \to 0$ in $C^0$ and consequently for each $\delta > 0$ we have

\begin{equation}
|||\xi_n|||_{p; C(\delta)} \to 0.
\end{equation}

On the other hand, for a fixed small $\delta$ and all large $n$, the maps $g_n$ lie in the neighborhoods $N_f$ of Lemmas 7.1 and 7.4. Applying the interior estimate (7.1) on $B(2\delta)$, we have

\begin{align*}
1 &= |||\xi_n|||_{1,p} \leq |||\xi_n|||_{1,p; B(2\delta)} + |||\xi_n|||_{1,p; C(2\delta)} \\
&\leq c_1 |||L_{g_n} \xi_n|||_{p; B(8\delta)} + c_2 |||\xi_n|||_{1,p; B(8\delta) \setminus B(2\delta)} + |||\xi_n|||_{1,p; C(2\delta)} \\
&\leq c_1 |||L_{g_n} \xi_n|||_p + c_2 |||\xi_n|||_{1,p; C(2\delta)}.
\end{align*}

After bounding the last term by the exterior estimate (7.10) with $\varepsilon = 1/2c_3$, this becomes

\begin{align*}
1 &\leq c_4 |||L_{g_n} \xi_n|||_p + c_5 |||\xi_n|||_{p; C(\delta)} + \frac{1}{2} |||\xi_n|||_{1,p; C(\delta)}.
\end{align*}
This inequality, together with (7.18) and the normalization \(|\|\xi_n\|_{1,p} = 1\), contradicts the assumption that \(|\|L_{g_n}\xi_n\|_p \to 0\).

**Lemma 7.6.** Let \(f : D \to X\) be a smooth map from a disk \(D\) with Riemannian metric \(g\). Then any bounded weak solution of \(L_f \xi = 0\) on \(D \setminus \{0\}\) extends to a smooth solution of \(L_f \xi = 0\) on \(D\).

**Proof.** Fix a smooth non-increasing function \(\beta(t)\) of \(t \in \mathbb{R}\) with \(\beta = 1\) for \(t \leq \frac{1}{2}\) and \(\beta = 0\) for \(t \geq 1\). For \(\delta > 0\), set \(\beta_\delta = \beta(r/\delta)\) using polar coordinates on \(D\). Write \(L_f\) as \(L\) and \(\xi\) as \(\beta_\delta \xi + (1 - \beta_\delta)\xi\). Noting that \(d\beta\) has support on the disk \(D(\delta)\) and that \(|L((1 - \beta_\delta)\xi)| \leq |d\beta_\delta||\xi| \leq c\delta^{-1}|\xi|\), we have the following bounds on the \(L^2\) inner product:

\[
|\langle L^*L\eta,\xi\rangle| = |\langle L^*L\eta,\beta_\delta\xi\rangle| + |\langle L\eta,L(1 - \beta_\delta)\xi\rangle| \\
\leq \left(\|L^*L\eta\|_{2,D} + c\delta^{-1}\|L\eta\|_{2,D(\delta)}\right)\|\xi\|_\infty \sqrt{\text{vol}(D(\delta))}.
\]

The right-hand side vanishes as \(\delta \to 0\). Thus \(\xi\) is a bounded weak solution of \(L^*L\xi = 0\) on \(D\).

After a conformal change of metric, we can choose coordinates around the origin in which \(L\) has the form \(\overline{\partial} + A\) where \(A\) is a zeroth-order operator and \(L^*L = \Delta + B\) where \(B\) is a first order operator. Standard elliptic theory then implies that \(\xi\) extends across the origin to a smooth solution of \(L^*L\xi = 0\) on \(D\). Taking the inner product with \(\beta_\delta \xi\) and integrating by parts then shows that \(L\xi = 0\) on \(D\). \(\square\)

**Theorem 7.7.** For each \(p\) with \(2 < p \leq 2 + \lambda\), there is a constant \(c(p)\) and a neighborhood \(\mathcal{N}\) of the space of stable \(J_\alpha\)-holomorphic maps in \(\text{Map}_\lambda(N_D,d)\) such that, for every \(f \in \mathcal{N}\),

(7.19) \[L_f : \mathcal{E}_f \to \mathcal{F}_f\]

is a uniformly bounded Fredholm map with index \(L_f = -2\beta\) as in (3.10) and with

(7.20) \[|\|\xi\|_{1,p} \leq c(p) |\|L_f \xi\|_p \quad \forall \xi \in \mathcal{E}_f.\]

**Proof.** By Proposition 7.5, each stable \(J_\alpha\)-holomorphic map \(f\) has a neighborhood \(\mathcal{N}_f\) and an associated constant \(c(p,f)\) so that (7.17) holds for all \(g \in \mathcal{N}_f\). These sets \(\{\mathcal{N}_f\}\) cover the space of stable maps, so (7.20) follows by the Compactness Theorem 2.5.

We know from Proposition 5.6 that \(L_f\) is uniformly bounded for \(f \in \mathcal{N}\), and \(\ker L_f = 0\) by (7.20). Inequality (7.20) also implies that the range of \(L_f\) is closed: if \(L_f \xi_k \to \eta\) then applying (7.20) to \(\xi_k - \xi_k\) shows that \(\{\xi_k\}\) is Cauchy, so \(\xi_k \to \xi_0\) in \(\mathcal{E}_f\) with \(L_f \xi_0 = \lim L_f \xi_k = \eta\), so \(\eta \in \text{Im} L_f\). The proof is completed by noting that \(\dim \text{coker} L_f = 2\beta\) by Lemma 7.8 below. \(\square\)
Lemma 7.8. For each $p$ with $2 < p \leq 2 + \lambda$ and each $(C, f)$ in the neighborhood $\mathcal{N}$ of Theorem 7.7, we can choose a $2\beta$-dimensional subspace $W_f \subset \mathcal{F}_f$, consisting of smooth forms that vanish in a neighborhood of the nodes, that is complementary to the image of $L_f : \mathcal{E}_f \to \mathcal{F}_f$. Hence $\dim coker L_f = 2\beta$.

Proof. Fix $f \in \mathcal{N}$ and let $L^{1,p}(E_f)$ and $L^p(F_f)$ be the completions of $E_f$ and $F_f$ defined by (4.4) in the usual, unweighted $L^{1,p}$ and $L^p$ norms. By [FO, Lemma 12.2] (see also [MS, Theorem C.1.10]) the modified linearization (4.5) extends to a bounded Fredholm map $L_f : L^{1,p}(E_f) \to L^p(F_f)$ whose index is $-2\beta$ and whose kernel vanishes by Theorem 4.2. Hence we can choose linearly independent $(0, 1)$ forms \{\(w_j \mid j = 1, \ldots, 2\beta\}\} in $L^p(F_f)$ so that $W_f = \text{span}\{w_j\}$ is complementary to $\text{Im} L_f$. We can assume that each $w_j$ is smooth and vanishes in a neighborhood of all nodes because such forms are dense in $L^p$.

Then each $\eta \in L^p(F_f)$ can be uniquely written as

$$\eta = L_f \xi + w \tag{7.21}$$

for some $\xi \in L^{1,p}(E_f)$ and $w \in W_f$. Also observe that, because $\rho$ is bounded and $p \leq 2 + \lambda$, each $\eta \in \mathcal{F}_f$ satisfies

$$\int_C |\eta|^p \leq c \int_C \rho^{p-2-\lambda} |\eta|^p.$$

Thus $\mathcal{F}_f \subset L^p(F_f)$. The same inequality for the weighted norm (5.2) shows that $\mathcal{E}_f \subset L^{1,p}(E_f)$. We also have $W_f \subset \mathcal{F}_f$ because $\rho^{-1}$ is bounded outside the set where all $w \in W_f$ vanish.

The lemma follows easily: each $\eta \in \mathcal{F}_f$ lies in $L^p(F_f)$, so can be written in the form (7.21) for some unique $\xi \in L^{1,p}(E_f)$ and $w \in W_f$. We can then apply Proposition 7.5 to $L_f \xi = \eta - w \in \mathcal{F}_f$ to conclude that $\xi \in \mathcal{E}_f$. Thus each $\eta \in \mathcal{F}_f$ can be written as the sum of an element in $L_f \mathcal{E}_f$ and a $w \in W_f$, and uniqueness holds because $\mathcal{E}_f \subset L^{1,p}(E_f)$. We conclude that $\dim coker L_f = \dim W_f = 2\beta$. \(\Box\)

8. Obstruction bundle $\mathcal{O}b$. Abstractly, $\mathcal{O}b$ is the topological vector bundle whose fiber at a $J_\alpha$-holomorphic map $f : C \to N_D$ is $coker L_f$. Thus it is defined by the exact sequence

$$0 \to \mathcal{E} \overset{L}{\to} \mathcal{F} \overset{p}{\to} \mathcal{O}b \to 0$$

of topological vector bundles over $\text{Map}_\lambda(X)$. The goal of this section is to give a concrete realization of $\mathcal{O}b$ and show that it is a locally trivial bundle on the space
of maps. For this, we will split the sequence

\[ 0 \longrightarrow \mathcal{E}_f \xrightarrow{L_f} \mathcal{F}_f \xrightarrow{\rho} \text{coker } L_f \longrightarrow 0 \]

by regarding coker \( L_f \) as a subspace of \( \mathcal{F}_f \) for each map \( f \). The key issue is constructing a splitting that is locally trivial around maps with nodal domains.

Consider the space \( \text{Map}_{g,n}(N_D,d) \) of maps into the open complex surface \( N_D \) that represent the class \( d[D] \). The following theorem is the main application of the analysis done in previous sections.

**Theorem 8.1.** There is a locally trivial real vector bundle \( \text{Ob} \) defined in a \( \lambda \)-topology neighborhood \( N \) of \( \text{Map}_{g,n}(N_D,d) \) in \( \text{Map}_{g,n}(N_D,d) \) such that the fiber of \( \text{Ob} \) at each \( f \in N \) lies in \( \mathcal{F}_f \), is complementary to the image of \( L_f \), and has the same dimension as coker \( L_f \). This bundle \( \text{Ob} \) has a canonical orientation.

The remainder of this section proves Theorem 8.1 in four steps. The first step adopts the method of Fukaya and Ono [FO]. Steps 2 and 3 show that the cokernel bundle is a locally trivial vector bundle; this is the key feature of our situation that does not occur in [FO]. Step 4 constructs an embedding of the cokernel bundle into the bundle \( \mathcal{F} \). In these steps and in the subsequent sections we assume that \( p \) lies in the range \( 2 < p \leq 2 + \lambda \) in which Theorem 7.7 and Lemma 7.8 are valid.

**Step 1. The fiber \( \text{Ob}_f \) at a map \( f : C \to N_D \).** For a fixed \( f \in \overline{\text{Map}}_{g,n}(D,d) \) the subspace \( W_f \) of Lemma 7.8 specifies a (non-canonical) splitting of (8.1). As in Lemma 7.8, write \( W_f \) as the space of linearly independent \((0,1)\) forms \( \{w_j \mid j = 1, \ldots, 2\beta\} \) in \( \mathcal{F}_f \). Also consider the subspace

\[ \mathcal{P}_0 = \Omega_0^{0,1}(T^*U \otimes N) \]

of the space (1.9) of Ruan-Tian perturbations that have values in the subspace \( N \subset TN_D \) and which vanish in some open set containing all nodes. For each \( v \in \mathcal{P}_0 \) the restriction of \( v \) to the graph of \( f \), defined as in (1.10), is an element \( v_f \in \Omega_0^{0,1}(C,f^*N) \) that vanishes near all nodes. The following lemma shows that, conversely, all such elements of \( \Omega_0^{0,1}(C,f^*N) \) arise as restrictions of elements of \( \mathcal{P}_0 \).

**Lemma 8.2.** For each \( w \in \Omega_0^{0,1}(C,f^*N) \), there is a \( v \in \mathcal{P}_0 \) with \( v_f = w \).

**Proof.** Fix \( \delta \) small enough that the support of \( w \) lies in \( C(2\delta) \). The graph \( G_f = \{(x,f(x)) \mid x \in C(\delta)\} \) is a submanifold of \( C(\delta) \times N_D \), so has a \( 2\varepsilon \)-tubular neighborhood \( \mathcal{O} \) consisting of points \((x,y)\) such that there is a unique minimal geodesic in \( N_D \) from \( y \) to \( f(x) \). Parallel transporting the fibers of \( N \) along these geodesics trivializes \( N \) over \( \mathcal{O} \). Fix a cutoff function \( \beta \in C^{\infty}(C(\delta) \times N_D) \) with
support on $\mathcal{O}$ and with $\beta \equiv 1$ on the $\varepsilon$-tubular neighborhood of $G_f$. Then, regarding $w$ as a form on $G_f$, we can extend to $\mathcal{O}$ by parallel transport, multiply by $\beta$, and extend by zero to obtain a section $\beta w$ of $T^*C(\delta) \boxtimes N$ over $C(\delta) \times N_D$.

Now fix a local trivialization $\phi: C(\delta) \times V \to U$ of the universal curve $\overline{U}$ around $C$ as in (2.4) and write $\phi^{-1} = (\tau_1, \tau_2)$. Choose a smooth cutoff function $\beta_U$ on $U$ with support on $\pi^{-1}(U)$ and with $\beta_U \equiv 1$ on a smaller neighborhood $\pi^{-1}(U')$ of $C$. The section $\tilde{v} = \beta_U \tau_1^*(\beta w)$ then extends by zero to a section of $T^*U \boxtimes N$ over $U \times N_D$. The $Jj$-antilinear component $v = \frac{1}{2}(\tilde{v} + J \circ \tilde{v} \circ j)$ is the desired $(0,1)$ form.

□

Step 2. Charts for the cokernel bundle. Fix $(C,f) \in \overline{\mathcal{M}}_{g,n}(D,d)$ and $W_f = \text{span}\{w_j\}$ as in Step 1. In light of Lemma 8.2, we can extend the forms in $W_f$ to obtain a vector space

$$V_f = \text{span}\{v_j\} \subset \mathcal{P}_0.$$ 

Given a neighborhood $N_f$ of $(C,f)$ in the space of maps, we can regard $V_f$ as a trivial vector bundle $V_f \times N_f$ over $N_f$. For each map $g \in N_f$ the composition of the restriction (1.10) and the projection $\rho$ in (8.1) gives a linear map $R$ defined by $R(v,g) = \rho(v_g)$ and a diagram

$$
\begin{array}{ccc}
V_f \times N_f & \xrightarrow{R} & \text{coker } L \\
\downarrow & & \downarrow \\
N_f & \xleftarrow{\text{coker } L} & \end{array}
$$

where coker $L$ is the topological vector bundle whose fiber at $g$ is coker $L_g$.

**Lemma 8.3.** Each $J_\alpha$-holomorphic map $f$ has a neighborhood $N_f$ in $\mathcal{M}_{g,n}(N_D,d)$ for which the map $R$ in (8.3) is injective.

**Proof.** By Theorem 7.7 there is a neighborhood $N$ of $\overline{\mathcal{M}}_{g,n}(D,d)$ such that for every $g \in N$ we have ker $L_g = 0$ and dim coker $L_g = 2\beta$. In particular, for each $g \in N$, coker $L_g$ has the same dimension as $V_f$. It suffices to find a neighborhood of $f$ on which $R$ is injective on fibers.

Let $S_f$ denote the unit sphere in the finite-dimensional vector space $V_f$ defined by the condition $\|v\|_\infty = 1$. Because $S_f$ is compact and im $L_g$ is closed, the infimum

$$\varepsilon_g = \inf \left\{ \|L_g \xi - v_g\|_p : \xi \in \mathcal{E}_g \text{ and } v \in S_f \right\}
$$

is realized for each $g$ and is equal to 0 if and only if $R(\cdot, g)$ is not injective. Thus, by our choice $V_f$, we have $\varepsilon_f > 0$, and we must show that $\varepsilon_g > 0$ for all $g$ near $f$. 

Suppose not. Then there is a sequence \((C_n, g_n)\) converging to \((C, f)\) in the \(\lambda\)-topology and corresponding sections \(\xi_n \in E_{g_n}\) and \(v_n \in S_f\) satisfying

\[
L_g \xi_n = (v_n)_{g_n}.
\]

Fix any \(\delta > 0\) small enough that the support of each \((v_n)_{g_n}\) is contained in \(C(\delta)\) and, as in the proof of Lemma 7.4, identify the domains \(C_n(\delta)\) with \(C(\delta)\) for all large \(n\). We then have the following three facts.

(a) Convergence in the \(\lambda\)-topology implies \(C^0\) convergence. Hence, after identifying the domains by a trivialization \((2.4)\), \(\|v_{g_n} - v_g\|_p \to 0\) because the weight \(\rho\) in the norm \((5.3)\) is bounded on the union of the supports of the \(v_{g_n}\). The triangle inequality then shows that \(\|\|\|v_{g_n} - v_g\|_p \to 0\).

(b) Lemma 5.3, Theorem 7.7, and the compactness of \(S_f\) yield a sup bound on \(\xi_n\):

\[
\|\xi_n\|_\infty \leq c_1 \|\xi_n\|_{1,p} \leq c_2 \|L_g \xi_n\|_p = c_2 \|(v_n)_{g_n}\|_p < c_3
\]

where the constants \(c_1, c_2\) and \(c_3\) are independent of \(g_n\) and these norms are on all of \(C_n\).

(c) Covering \(C(\delta)\) by disks on which \((7.15)\) holds shows that there is a \(c_4\) such that for each \(\varepsilon > 0\) there is an \(N\) so that

\[
\|L_f \xi_n - (v_n)_{g_n}\|_{p;C(\delta)} = \|(L_f - L_g) \xi_n\|_{p;C(\delta)} \leq c_4 \varepsilon \|\xi_n\|_{1,p} \quad \forall n \geq N.
\]

Using Theorem 7.7 and writing \(L_f \xi_n = (L_f \xi_n - (v_n)_{g_n}) + (v_n)_{g_n}\), we see that

\[
\|\xi_n - \xi_m\|_{1,p;C(\delta)} \leq c_5 \|L_f (\xi_n - \xi_m)\|_{p;C(\delta)}
\]

is bounded by

\[
c_5 \left( \frac{\|L_f \xi_n - (v_n)_{g_n}\|_{p;C(\delta)} + \|L_f \xi_m - (v_m)_{g_m}\|_{p;C(\delta)}}{\|L_f \xi_n - (v_n)_{g_n}\|_{p;C(\delta)}} \right)
\]

for all large \(m\) and \(n\). This, together with facts (a)–(c), shows that \(\{\xi_n\}\) is Cauchy in the norm \((5.2)\) on \(C(\delta)\) and converges on \(C(\hat{\delta})\) to a limit \(\xi\) that satisfies \(L_f \xi = v_f\).

Now replace \(\delta\) by \(\delta/2\) and repeat to obtain a further subsequence that converges on \(C(\hat{\delta}/2)\) to a limit that extends the previous \(\xi\). Repeat with \(\delta/4\), etc. Then the diagonal sequence converges on \(C_f\) \(\setminus\) \{nodes\} to a limit \(\xi\) that satisfies \(L_f \xi = v_f\). Because \(v_f \equiv 0\) near each node, Lemma 7.6 shows that \(\xi\) extends to a solution of \(L_f \xi = v_f\) on all of \(C\). Then Proposition 7.5 shows that \(\|\xi\|_{1,p}\) is finite, and Corollary 5.5 shows that \(\xi\) satisfies the matching condition \((4.4)\) at the nodes. Thus \(\xi \in E_f\), contradicting the assumption that \(\varepsilon_f > 0\).

\(\square\)
Step 3. The transition maps for the cokernel bundle. In order to show 
coker $L$ is a vector bundle, it suffices to show that for any two maps $f_1$ and $f_2$
with $\mathcal{N}_{f_1} \cap \mathcal{N}_{f_2} \neq \emptyset$ and for each fixed $v \in V_{f_1}$ the map 
\begin{equation}
\mathcal{N}_{f_1} \cap \mathcal{N}_{f_2} \rightarrow V_{f_2} \text{ defined by } g \rightarrow R_2^{-1} \circ R_1(v, g)
\end{equation}
is continuous where $R_i : V_{f_i} \times \mathcal{N}_{f_i} \rightarrow \text{coker } L$ is a linear map defined in (8.3) and $\mathcal{N}_{f_1}$ and $\mathcal{N}_{f_2}$ are neighborhoods as in Lemma 8.3.

LEMMA 8.4. The map (8.7) is continuous. Consequently, coker $L$ is a locally 
trivial vector bundle.

Proof. With the above notation, for each $g \in \mathcal{N}_{f_1} \cap \mathcal{N}_{f_2}$, Lemma 8.3 shows 
that $\{u_g \mid u \in V_{f_2}\}$ is complementary to the image of $L_g$. Hence, as in the proof of 
Lemma 7.8, for each $v_g$ there exist unique $\xi \in \mathcal{E}_g$ and $u \in V_{f_2}$ with $v_g = L_g \xi + u_g$. 
Therefore
\begin{equation}
L_g \xi = v_g - u_g \text{ and } R_2^{-1} \circ R_1(v, g) = u.
\end{equation}
We claim that $u$ depends continuously on $g$. To that end, consider sequences $g_n \rightarrow g$, $u_n \in V_{f_2}$ and $\xi_n$ such that
\begin{equation}
L_{g_n} (\xi_n) = v_{g_n} - (u_n)_{g_n}.
\end{equation}

First consider the case where there is a uniform bound on the norms $\|u_n\|_{\infty}$. Because $V_{f_2}$ is finite-dimensional, we can assume, after passing to a subsequence, 
that $u_n$ converges to an element $u_0 \in V_{f_2}$ in the $C^0$ norm. Then (8.9) is the same 
as (8.5) with $v$ and $v_n$ replaced by $z = v - u_0$ and $z_n = v - u_n$ respectively. As 
in statement (a) in the proof of Lemma 8.3, the convergence $g_n \rightarrow g$ implies that 
$\|(z_n)_{g_n} - z\|_p \rightarrow 0$. We can therefore repeat the argument of Lemma 8.3 to con-
clude that $\{\xi_n\}$ converge on compact sets away from the nodes of $C$ to a limit 
$\xi_0$ that satisfies $L_g (\xi_0) = v_g - (u_0)_{g}$. The uniqueness of $u$ in (8.8) then implies $u = u_0$. As a result, the sequence $u_n$—not just a subsequence—converges to $u$. Thus $u$ depends continuously on $g$.

In the remaining case, $u_n$ is not bounded. After passing to a subsequence, we can assume that $\|u_n\|_{\infty} > n$ for all $n$. Note that $\|(u_n)_{g_n}\|_p \leq c\|u_n\|_{\infty}$ for some 
uniform constant $c$. Now, dividing equation (8.9) by $\|u_n\|_{\infty}$, we have
\begin{equation}
L_{g_n} (\eta_n) = \alpha_{g_n} - (\beta_n)_{g_n}
\end{equation}
with $\|\alpha_{g_n}\|_p \leq \frac{1}{n} \limsup_{n} \|v_{g_n}\|_p \rightarrow 0$ and with $\|\beta_n\|_{\infty} = 1$ and $\|(\beta_n)_{g_n}\|_p \leq c$ for all $n$. Again repeating the convergence argument of Lemma 8.3 we obtain, in 
the limit, a $\zeta$ that satisfies $L_g \zeta = -\beta_{g}$ where $\beta \neq 0$ is the limit of the sequence $\beta_n$ 
in $V_{f_2}$. But this means that $R_2(\beta, g) = 0$, contradicting Lemma 8.3. Therefore, the 
map (8.7) is continuous. The lemma follows. \qed
Step 4. Definition of $O_b$. The procedure of Step 2 can be applied to each $J_\alpha$-holomorphic map $f$ to obtain a pair $(V_f, N_f)$. By compactness, we can choose a finite set \{\{f_i\}\} of $J_\alpha$-holomorphic maps so that $N_{f_i}$ covers $\overline{M}_{g,n}(D,d)$. The vector spaces $V_{f_i}$ consist of $(0,1)$ forms and together define a single finite-dimensional vector space span $\{V_{f_i}\}$. Let $V$ denote the trivial vector bundle $V = N \times \text{span} \{V_{f_i}\}$ over $N = \bigcup N_{f_i}$. We then have an exact sequence of locally trivial vector bundles over $N$:

$$0 \rightarrow \text{ker } \sigma \rightarrow V \xrightarrow{\sigma} \text{coker } L \rightarrow 0$$

where $\sigma$ is the composition of the restriction map (1.10) with the projection to coker $L$. Now, using a metric on the vector bundle $V$ induced from metrics on $U$ and $N_D$, we define the obstruction bundle $O_b$ over $N$ to be the orthogonal complement of $\text{ker } \sigma$ in $V$. Then $\sigma$ restricts to a vector bundle isomorphism $O_b \cong \text{coker } L$ over $N$. Lastly, the fact $O_b$ has a canonical orientation is proved in Lemma 11.1 below. This completes the proof of Theorem 8.1.

9. A generalized Image Localization Lemma. In this section we generalize the Image Localization Lemma of Section 1, showing that it applies not just to solutions of (1.4) but, more generally, to maps $f : C \rightarrow N_D$ that satisfy the perturbed $J_\alpha$-holomorphic map equation (1.8) provided that $\nu$ is small and its vertical component lies in the fiber of the obstruction bundle. The proof uses a renormalization argument similar to those in [IP1, Sections 6 and 7]. In the statement of the theorem, and throughout this section, we will use the decomposition (4.1) to write the perturbation $\nu$ as the sum $\nu^T + \nu^N$ of horizontal and vertical components. The conclusion is the same as in the original localization lemma: the images of the maps lie in the divisor of $\alpha$, which is the zero section of the bundle $N \rightarrow D$.

Theorem 9.1. (Image Localization with Perturbations) Fix $E > 0$ and a neighborhood $U$ of the zero section in $N_D$. Then there is a $\delta_0 > 0$ such that if $\nu = \nu^T + \nu^N$ with $\|\nu\|_{C^1} \leq \delta_0$, then the image of every map $f : C \rightarrow N_D$ in $\text{Map}_\lambda^E(U)$ satisfying

$$\overline{\partial}_f f - K_\alpha(\partial_f f) = \nu^T_f + P_f(\nu^N_f)$$

(9.1)

lies in $D$ where $P_f$ is the $L^2$-orthogonal projection onto the fiber $O_b$. 

Proof: If this statement is false, there is a sequence $\{\nu_n\}$ of the stated form with $\nu_n \rightarrow 0$ in $C^1$, and a sequence of maps $f_n : C_n \rightarrow N_D$ in $\text{Map}_\lambda^E(U)$ satisfying the equation (9.1), each with at least one point not mapped into $D$. By Gromov compactness and Theorem 2.5 we may assume, after passing to a subsequence, that the $f_n$ converge, in $C^0 \cap L^{1,2}$ and in $C^\infty$ away from the nodes, to a $J_\alpha$-holomorphic map $f_0 : C_0 \rightarrow N_D$. By Lemma 1.1 the image of $f_0$ lies in $D \subset N_D$. 
We can now renormalize. Let $\phi_n$ be the projection of $f_n$ into $D$ and let $R_n : N_D \to N_D$ be dilation in the fibers by a factor of $1/t_n$, where each $t_n$ is chosen so that the image of renormalized map $F_n = R_n \circ f_n$ lies in the unit disk bundle, but not in any smaller disk bundle. Because the images of the $f_n$ converge pointwise to the zero section we have $t_n \to 0$.

Next, write $F_n$ as the graph $(\phi_n, \xi_n)$ in $N_D$ where $\xi_n$ is a section of $\partial^* N$. Then the original maps are given by $f_n = (\phi_n, t_n \xi_n)$ and $\phi_n \to f_0$ as $n \to \infty$. For each map $f$, write $\Phi(f) = \partial_j f - K_\alpha \partial_j f$ for the left-hand side of (9.1). After trivializing the pullback $\pi^* N$ by parallel transport $T$ along the fibers of $\pi : N_D \to D$, we can compare the vertical components $\Phi^N$ of $\Phi(\phi_n)$ and $\Phi(f_n)$ by writing $f_n = \exp_{\phi_n}(t_n \xi_n)$ and applying the first variation formula on $C_n$:

\[
T \Phi^N(f_n) = \Phi^N(\phi_n) + L_{\phi_n}(t_n \xi_n) + O \left( |t_n \xi_n|^2 \right).
\]

Here $L_{\phi_n}$ is given by equation (4.3) along the image of $\phi_n$ and $\Phi^N(\phi_n) = 0$ since the image of $\phi_n$ lies in $D$. We also have

\[
TP_{f_n}(\nu^N_{f_n}) = \nu_{\phi_n} + \nabla_{t_n \xi_n}(P_{\phi_n}(\nu_{\phi_n})) + O \left( |t_n \xi_n|^2 \right)
\]

where we have simplified notation by writing $(\nu_n)_{\phi_n} = \nu_{\phi_n}$. Since $\Phi^N(f_n) = P_{f_n}(\nu^N_{f_n})$ by equation (9.1) and $\|\xi_n\|_\infty = 1$, it follows from (9.2) and (9.3) that

\[
t_n^{-1} P_{\phi_n}(\nu^N_{\phi_n}) - L_{\phi_n}(\xi_n) = -(\nabla_{\xi_n} P_{\phi_n})(\nu^N_{\phi_n}) - P_{\phi_n}(\nabla_{\xi_n} \nu^N_{\phi_n}) + O(t_n).
\]

By definition, $P$ is the $L^2$ projection onto a subspace spanned by smooth forms with support away from the nodes, where $\phi_n \to f_0$ in $C^\infty$. Writing that projection as an integral, one sees that $P_{\phi_n}$ and $\nabla P_{\phi_n}$ are bounded, uniformly in $n$. The assumption that $\nu_n \to 0$ in $C^1$ then implies that the right-hand side of (9.4) vanishes in the limit $n \to \infty$.

Recall that $Ob_{\phi_n}$ is a complementary subspace to the image of $L_{\phi_n}$. In fact, the proof of Lemma 8.3 shows that the quantity $\varepsilon_{\phi}$ defined by (8.4), which measures the angle between these subspaces, satisfies $\varepsilon_{\phi_n} > c$ for some positive constant $c$ and all sufficiently large $n$. We therefore conclude that

\[
|t_n^{-1} P_{\phi_n}(\nu^N_{\phi_n})| \to 0 \quad \text{and} \quad L_{\phi_n}(\xi_n) \to 0
\]
as $n \to \infty$. Dividing (9.3) by $t_n$ and using these limits (noting that parallel transport preserves norms) yields the stronger statement that

\[
|t_n^{-1} P_{f_n}(\nu^N_{f_n})| \to 0 \quad \text{and} \quad L_{\phi_n}(\xi_n) \to 0 \quad \text{as} \quad n \to \infty.
\]

Now return to the equation $F_n = R_n \circ f_n$. Note that $dF_n = (R_n)_* df_n$ and, since $R_n$ is a holomorphic diffeomorphism of the total space of $N_D$, $J$ commutes with $(R_n)_*$. Letting $K_n$ denote the pullback endomorphism $(R_n)^{-1} * K_\alpha =
\( (R_n)_*, K_\alpha (R_n^{-1})_* \), equation (9.1) can be rewritten as

\[
(9.6) \quad \bar{\partial}_J F_n - K_n \partial_J F_n = (R_n)_* \left[ \nu^T_{f_n} + P_{f_n} (\nu^N_{f_n}) \right].
\]

Consider the limit as \( n \to \infty \) of each term in (9.6). Under the splitting (4.1), \((R_n)_*\) is bounded on horizontal vectors and is multiplication by \(1/t_n\) on vertical vectors, so by (9.5)

\[
(9.7) \quad \left| \left( R_n \right)_* \left[ \nu^T_{f_n} + P_{f_n} (\nu^N_{f_n}) \right] \right| \leq c \left| \nu^T_{f_n} \right| + \left| t_n^{-1} P_{f_n} (\nu^N_{f_n}) \right| \to 0.
\]

Because \( K_\alpha \) is smooth and vanishes along the zero section, there is an endomorphism \( K' \) depending smoothly on the projection of \( x \) into \( D \) such that \( K_\alpha (tx) = tK'_\alpha + O(t^2) \) as \( t \to 0 \). Hence the pullback \( K_n \) satisfies

\[
K_n = (R_n)_*(t_nK'_\alpha + O(t^2))(R_n^{-1})_*
\]

as \( t_n \to 0 \). Thus \( \{ K_n \} \) converges to an endomorphism \( \hat{K} \) whose only non-zero components take horizontal vectors to vertical vectors.

We can now reexpress (9.6) as a \( J_n \)-holomorphic map equation. As in (1.2), \( K_n \) anti-commutes with \( J \) and satisfies \( K_n^2 = -|\alpha_n|^2 I_d \) where \( \alpha_n \) is the \( (0,2) \) form whose value at \( x \) is \( \alpha_{t_n,x} \). It follows that \( I_d + J K_n \) has a bounded inverse, namely \( (1 + |\alpha_n|^2)^{-1} (I_d - J K_n) \), that \( J_n = (I_d + J K_n)^{-1} J (I_d + J K_n) \) is an almost complex structure, and that \( F_n \) satisfies the equation

\[
(9.8) \quad \bar{\partial}_J F_n = \frac{1}{2} (dF_n + J_n dF_n) = (I_d + J K_n)^{-1} (R_n)_* \left[ \nu^T_{f_n} + P_{f_n} (\nu^N_{f_n}) \right].
\]

The convergence \( K_n \to \hat{K} \) then implies that \( \{ J_n \} \) converges in \( C^0 \) to the almost complex structure \( \hat{J} = (I_d + J \hat{K})^{-1} J (I_d + J \hat{K}) \), and (9.7) implies that the right-hand side of (9.8) converges to 0 in \( C^0 \).

At this point we have established that the maps \( F_n : C_0 \to N_D \) satisfy the \( J_n \)-holomorphic equation with a perturbation term that goes to 0 in \( C^0 \). By Gromov compactness (cf. [IP1, Theorem 1.6]) there is a connected curve \( C_0 \) and smooth map \( F_0 : C_0 \to N_D \) such that, after passing to a subsequence, \( F_n \) converges to \( F_0 \) in \( C^0 \cap L^{1,2} \) and in \( C^\infty \) away from the nodes of \( C_0 \). It follows that \( \pi \circ F_0 = f_0 \) and hence \( F_0 \) defines a section \( \xi_0 \) of the pullback bundle \( f_0^* N \) by the formula

\[
F_0 = \left( f_0, \xi_0 \right).
\]
If $C_0$ is smooth, we have $\phi_n \to f_0$ and $\xi_n \to \xi_0$ in $C^\infty$. Then (9.5) and the normalization $\|\xi_n\|_\infty = 1$ imply that $\xi_0$ is a non-trivial solution of

$$L_{f_0}(\xi_0) = 0.$$ 

This contradicts the Vanishing Theorem 4.2.

When $C_0$ is nodal we get a similar contradiction on some irreducible component of $C_0$, as follows. Note that, because $F_0$ is $\hat{J}$-holomorphic, the image $F_0(C_i)$ of each irreducible component $C_i$ is either a single point or represents a non-trivial homology class. If all components that carry a non-trivial homology class were mapped into $D$ then, since $C_0$ is connected and $F_0$ is continuous, the entire image would lie in $D$, contradicting our choice of renormalization. Thus there exists a component $C$ of $C_0$ with $F_0(C) \notin D$. On this component, $\xi_0$ is not zero. The argument in the proof of Proposition 7.5 then shows that $\xi_n \to \xi_0$ in $C^\infty$ on each compact subset of $C \setminus \{\text{nodes}\}$ and that $L_{f_0}\xi_0 = 0$. This again contradicts Theorem 4.2. □

10. The proof of the Main Theorem. We now turn to the proof of the Main Theorem stated in the introduction: the local GW invariants of a spin curve $(D,N)$ are given by the cap product

$$GW_{g,n}^{\text{loc}}(N_D, d) = \hat{e}_*(\overline{\mathcal{M}}_{g,n}(D,d)^\text{vir} \cap e(Ob))$$

where $Ob$ is the obstruction bundle defined in Section 8. The basic idea is to turn on a generic Ruan-Tian perturbation of the type described in Theorem 9.1. The perturbation defines a section of $Ob$ whose zero set represents the Euler class $e(Ob)$, and on the other hand is cobordant to a cycle representing the local GW invariant. The proof consists of the three steps done in this section, together with the discussion of orientations in Section 11.

To simplify notation, we set

$$\Map_D = \Map_{g,n}(D,d), \quad Y_D = \overline{\mathcal{M}}_{g,n} \times D^n$$

$$\Map = \Map_{g,n}(N_D,d), \quad Y = \overline{\mathcal{M}}_{g,n} \times N_D^n.$$ 

Let $\hat{F} \to \Map$ be the topological vector bundle whose fiber at $f$ is $\Omega^{0,1}(f^*TN_D)$. This bundle has a section $\Phi$ given by the $J_\alpha$-holomorphic map equation $\Phi(f) = \overline{\partial}_J f - K_\alpha(\overline{\partial}_J f)j$. For each perturbation $\nu$ in $P$ defined in (1.9), one can perturb $\Phi$ to obtain a section

$$\Phi_\nu(f) = \Phi(f) - \nu f$$

where $\nu f$ is the restriction of $\nu$ to the graph of $f$ as in (1.10). The zero set $\overline{\mathcal{M}}' = \Phi_\nu^{-1}(0)$ is the moduli space of $(J_\alpha, \nu)$-holomorphic maps into $N_D$. 

By Theorem 8.1, the bundle $Ob$ is defined on a neighborhood $\mathcal{N}$ of the moduli space of $J_\alpha$-holomorphic maps inside $\text{Map}$. Following [RT2], one can decompose $\mathcal{N}$ into strata $\mathcal{N}_B$ indexed by a finite collection of sets $B$ that specify: (i) a homeomorphism type of the domain as a curve with marked points and (ii) a degree of map associated to each component of the domain.

**Step 1.** As in Section 9, we can decompose $\nu$ according to the splitting of $f^*TN_D$ into horizontal and vertical subspaces. Fix a $C^1$-small perturbation $\nu_T$ that is generic in the subspace $\mathbb{P}_T \subset \mathbb{P}$ of perturbations that lie in the horizontal subspace and consider the section $\Phi_{\nu_T}$ defined by (10.2).

By the Image Localization Theorem 9.1 the images of all $(J_\alpha, \nu_T)$-holomorphic maps lie in $D$. The transversality arguments of Section 3 in [RT2], applied to maps into $D$, imply that the moduli space

$$M = \Phi_{\nu_T}^{-1}(0) \subset \mathcal{N} \cap \text{Map}_D$$

has a stratification such that each stratum $\mathcal{M}_B = \overline{M} \cap \mathcal{N}_B$ is a smooth oriented manifold of dimension $4\beta + 2n - 2k_B$ where $\beta = d(1 - h) + g - 1$ as in (3.10) and $k_B$ is the number of nodes of the domains of maps in $\mathcal{N}_B$.

Let $\mathcal{M}$ be the top stratum consisting of maps with smooth domains. Now apply the construction described at the end of Section 3: fix a neighborhood $U$ of the image $\hat{\text{ev}}(\partial \mathcal{M})$ of the boundary $\partial \overline{M} = \overline{\mathcal{M}} \setminus \mathcal{M}$ and consider the manifold with boundary $\overline{\mathcal{M}}_U \subset \mathcal{M}$ as in Definition 3.1. The following lemma shows that space $\overline{\mathcal{M}}_U$ represents the Li-Tian virtual fundamental class (3.4) for $(X, A) = (D, d)$ modulo small neighborhoods of its boundary.

**Lemma 10.1.** Let $\hat{U} = \hat{\text{ev}}^{-1}(\overline{U})$ be the preimage of $\overline{U}$ under the evaluation map (0.4) on $\text{Map}_D$. Then

$$j_*[\overline{\mathcal{M}}_{g,n}(D, d)]^{\text{vir}} = i_*[\overline{\mathcal{M}}_U] \in H_{4\beta + 2n}(\text{Map}_D, \hat{U})$$

where $j : \text{Map}_D \to (\text{Map}_D, \hat{U})$ and $i : (\overline{\mathcal{M}}_U, \partial \overline{\mathcal{M}}_U) \to (\text{Map}_D, \hat{U})$ are inclusion maps.

**Proof.** Let $\hat{\mathcal{F}}_D \to \text{Map}_D$ be the bundle whose fiber at $f$ is $\Omega^{0,1}(f^*TD)$. Since $K_\alpha \equiv 0$ on $D$, we can regard $\Phi_{\nu_T}$ as a section of $\hat{\mathcal{F}}_D$. The arguments used to prove [LT2, Proposition 3.4] then show how the section $\Phi_{\nu_T}$ gives rise to a cover of the moduli space $\overline{M} = \Phi_{\nu_T}^{-1}(0)$ by finitely many smooth approximations $\{(W_k, F_k)\}$. This means that

- each $W_k$ is open in $\text{Map}_D$ and $\overline{\mathcal{M}} \subset \bigcup W_k$, and
- each $F_k$ is a subbundle of $\hat{\mathcal{F}}_D$ over $W_k$ with finite rank such that $\Phi_{\nu_T}^{-1}(F_k) \subset W_k$ is smooth and $F_k$ restricts to a smooth bundle over $\Phi_{\nu_T}^{-1}(F_k)$ with smooth section $\Phi_{\nu_T}$.

Observe that, because the top stratum $\mathcal{M}$ is already smooth, we can assume that
\begin{itemize}
  \item $W_1$ consists of all maps with smooth domains (so $W_1 \cap \overline{M} = M$) and $F_1$ has rank zero.

  The proofs of [LT2, Proposition 2.2 and Theorem 1.2] describe how one can perturb the moduli space $\overline{M}$ inside the union of the smooth manifolds $\Phi^{-1}(F_k)$ to obtain a cycle that represents the virtual fundamental class $[\overline{M}_{g,n}(D,A)]^{\text{vir}}$.

  Now choose a neighborhood $V$ of the image $\tilde{ev}(\partial \overline{M})$ in $Y_D$ with $V \subset U$. Set $\tilde{V} = \tilde{ev}^{-1}(V)$ and replace each $W_i$ with $i \geq 2$ with $W_i \cap \tilde{V}$. Then the open set $W = \bigcup_{k>1} W_k$ lies in $\tilde{V}$. Following [LT2] we can then perturb $\overline{M} \cap W$ while keeping $\overline{M}$ fixed outside of $\tilde{V}$—hence on $\overline{M}_U$—to produce a cycle representing $[\overline{M}_{g,n}(D,A)]^{\text{vir}}$. Passing to homology proves the statement of the lemma. \hfill $\square$

\end{itemize}

Remark 10.2. The virtual fundamental class that appears in Lemma 10.1 is the Li-Tian class (3.4). We can verify that it is also the Ruan-Tian class: let $k : Y_D \to (Y_D, \mathcal{U})$ be an inclusion map. Since $\tilde{ev} \circ f = k \circ \tilde{ev}$, Lemma 10.1 gives $k_* \circ \tilde{ev}_*[\overline{M}_{g,n}(D,d)]^{\text{vir}} = \tilde{ev}_*[\overline{M}_U]$. The uniqueness statement in Lemma 3.2 then shows that

$$\tilde{ev}_*[\overline{M}_{g,n}(D,d)]^{\text{vir}} = GW_{g,n}(D,d) \in H_{4\beta+2n}(\overline{M}_{g,n} \times D^n; \mathbb{Q}).$$

Step 2. We now further perturb the section $\Phi_{\nu_T}$ by adding a section of the obstruction bundle $\mathcal{O}b$ induced from a Ruan-Tian perturbation $\mu$. Each $\mu \in \mathcal{P}$ defines a section $\hat{s}_\mu$ of the obstruction bundle $\mathcal{O}b$ over $\mathcal{N}$ by

$$\hat{s}_\mu(f) = P_f(\mu_f)$$

where $P_f$ is the $L^2$-orthogonal projection onto the fiber $\mathcal{O}b_f$. Let $s_\mu$ denote the restriction of $\hat{s}_\mu$ to the moduli space $\overline{M}$. Whenever $\mu$ has small $C^1$ norm, the Image Localization Theorem 9.1 implies that

$$\left(\Phi_{\nu_T} - \hat{s}_\mu\right)^{-1}(0) = \overline{M} \cap \hat{s}_\mu^{-1}(0) = s_\mu^{-1}(0).$$

Lemma 10.3. For generic $\mu$ in $\mathcal{P}$, the space (10.4) has a stratification indexed by $B$ such that each stratum $\mathcal{M}_B \cap s_\mu^{-1}(0)$ is a smooth manifold of dimension $2\beta+2n-2k_B$.

Proof. The proof is a transversality argument using the universal moduli space over the space of perturbations $\mathcal{P}$ (cf. [RT2, Theorem 3.1]). The smooth bundle

$$\mathcal{O}b \longrightarrow \mathcal{M}_B \times \mathcal{P}$$

has rank $2\beta$ and has a section $\sigma_B$ defined by $\sigma_B(f,\mu) = s_\mu(f)$ whose zero set is the universal moduli space associated with $B$. The differential of $\sigma_B$ at $(f,\mu)$ is

$$\left(\delta \sigma_B\right)_{(f,\mu)}(\xi, \chi) = (Ds_\mu)_{f}(\xi) - P_f(\chi_f) \quad \text{for } \xi \in T_f \mathcal{M}_B, \chi \in T_\mu \mathcal{P}.$$
where $Ds_\mu$ is the differential of the restriction of $s_\mu$ to $M_B$ and $\chi_f$ is the restriction of $\chi$ to the graph of $f$ as in (1.10). Since the map $\chi \to P_f(\chi_f)$ is onto, so is the differential $(D\sigma_B)(f,\mu)$. The universal moduli space $U = \sigma_B^{-1}(0)$ is therefore smooth. Now, consider the projection

$$\pi_B : U \to P$$

given by $\pi_B(f,\mu) = \mu$. Since $\pi_B$ is Fredholm, the Sard-Smale Theorem implies that for generic $\mu$ the fiber $\pi_B^{-1}(\mu) = M_B \cap s_\mu^{-1}(0)$ is a smooth manifold of dimension $\dim M_B - \text{rank} \, Ob$, which is $2\beta + 2n - 2k_B$. 

Fix a generic $\mu \in P$ as in Lemma 10.3 and set

$$\bar{Z} = s_\mu^{-1}(0) = (\Phi_{\nu \tau} - \hat{s}_\mu)^{-1}(0).$$

By Lemma 10.3 and the discussion above Lemma 3.2, applied to some neighborhood of $\hat{\ev}(\partial Z)$ where $\partial Z = \bar{Z} \cap \partial \bar{M}$, the image $\hat{\ev}(\bar{Z})$ defines a homology class

$$[\hat{\ev}(\bar{Z})] \in H_{2\beta + 2n}(Y_D; \mathbb{Q}) \cong H_{2\beta + 2n}(Y; \mathbb{Q}).$$

On the other hand, the local GW invariant class is determined by the image of the moduli space $\bar{M}' = \Phi_{\nu}^{-1}(0)$ for a generic $\nu \in P$ as in (3.9):

$$GW_{g,n}^{\text{loc}}(N_D, d) = [\hat{\ev}(\bar{M}')] \in H_{2\beta + 2n}(Y; \mathbb{Q}).$$

Thus the local invariant is defined in terms of the zero set of $\Phi_{\nu}$ for a fixed generic $\nu \in P$, while the class (10.6) is defined in terms of the zero set of $\Phi_{\nu \tau} - \hat{s}_\mu$. To show these are equal we introduce, for each pair $(\nu, \upsilon)$ in $P \times P$, a section of the bundle $\hat{F} \to \text{Map}$ defined by

$$\Phi_{\nu, \upsilon}(f) = \Phi(f) - \nu f - \hat{s}_\upsilon(f).$$

The transversality argument of Lemma 10.3, now applied to the universal moduli space over the parameter space $P \times P$, shows that, for generic small $(\nu, \upsilon)$ in $P \times P$, $\Phi_{\nu, \upsilon}^{-1}(0)$ has a stratification indexed by $B$ such that each stratum $N_B \cap \Phi_{\nu, \upsilon}^{-1}(0)$ is a smooth manifold of dimension $2\beta + 2n - 2k_B$. Standard cobordism arguments (cf. [RT2, Theorem 3.3]) then give

$$GW_{g,n}^{\text{loc}}(N_D, d) = [\hat{\ev}(\Phi_{\nu, \upsilon}^{-1}(0))] = [\hat{\ev}(\Phi_{\nu \tau, \mu}^{-1}(0))] = [\hat{\ev}(\bar{Z})].$$

**Step 3.** It remains to show that $[\hat{\ev}(\bar{Z})]$ equals to the right-hand side of (10.1). Again, to avoid issues of smoothness near $\partial M$, we work in relative homology. The following lemma is, in essence, the statement that the zero set of a generic section of a vector bundle is Poincaré dual (in relative homology) to the Euler class.
Lemma 10.4. Let $\tilde{Z}_U = \overline{MU} \cap \tilde{Z}$. Then

\[(10.9) \quad j_*([\overline{M}_{g,n}(D,d)]^\text{vir} \cap e(Ob)) = i_*[\tilde{Z}_U] \in H_{2\beta+2n}(\Map_D, \hat{U})\]

where $j : \Map_D \to (\Map_D, \hat{U})$ and $i : (\overline{MU}, \partial \overline{MU}) \to (\Map_D, \hat{U})$ are inclusion maps.

Proof. The obstruction bundle $Ob$ restricts to a smooth bundle $Ob_U$ over $\overline{MU}$. Let $s_U$ be the restriction of the section $s_\mu$ in (10.3) to $\overline{MU}$. Without loss of generality, we can assume $s_U$ is transverse to the zero section, so $\tilde{Z}_U = s_U^{-1}(0)$ is a compact smooth manifold with boundary.

Define a double $\hat{N}_U$ of $\overline{MU}$ by identifying two copies of $\overline{MU}$ along $\partial \overline{MU}$. Similarly, define a vector bundle $\hat{O}_U \to \hat{N}_U$ and its section $\hat{s}_U$ that are doubles of $Ob_U$ and $s_U$ respectively. Since $\hat{N}_U$ is a closed manifold, we have

\[(10.10) \quad [\hat{N}_U] \cap e(\hat{Ob}_U) = [\tilde{Z}_U]\]

where $\tilde{Z}_U = s_U^{-1}(0)$. Consider the following commutative diagram:

\[
\begin{array}{ccc}
H_{4\beta+2n}(\hat{N}_U) & \xrightarrow{\kappa_*} & H_{4\beta+2n}(\hat{N}_U, \hat{N}_U \setminus \hat{M}_U) \\
\cap e(\hat{Ob}_U) & \xrightarrow{\cap e(\hat{Ob}_U)} & H_{2\beta+2n}(\hat{N}_U, \hat{N}_U \setminus \hat{M}_U) \\
\cap e(\hat{Ob}_U) & \xrightarrow{\cap e(\hat{Ob}_U)} & H_{2\beta+2n}(\hat{N}_U, \hat{N}_U \setminus \hat{M}_U)
\end{array}
\]

where $\hat{M}^\beta_U = \overline{MU} \setminus \partial \overline{MU}$, $\kappa$ and $\iota$ are inclusion maps, each rectangle commutes by the naturality of the cap product, and the horizontal isomorphisms follow by excision. Consequently, (10.10), (10.11) and the facts $\kappa_*[\hat{N}_U] = \iota_*[\overline{MU}]$ and $\kappa_*[\tilde{Z}_U] = \iota_*[\tilde{Z}_U]$ show

\[ [\overline{MU}] \cap e(\hat{Ob}_U) = [\tilde{Z}_U] \in H_{2\beta+2n}(\overline{MU}, \partial \overline{MU}). \]

Now, (10.9) follows from this equality, Lemma 10.1 and the naturality of cap product.

Proof of Main Theorem. Recall that $\overline{MU}$ and $\tilde{Z}$ are decomposed into smooth strata indexed by sets $B$ such that $\dim \overline{M}_B = 4\beta + 2n - 2k_B$ and $\dim Z_B = 2\beta + 2n - 2k_B$ where $Z_B = \tilde{Z} \cap \overline{M}_B$. Because $Y_D$ is a compact manifold, any class in $H_*(Y_D; \mathbb{Q})$ can be represented by an embedded submanifold by Thom’s Theorem [Th]. We can thus choose a basis for $H_{m-2\beta}(Y_D; \mathbb{Q})$, where $m + 2n = \dim Y_D$, represented by submanifolds $D_i$ in general position with respect to all the restriction maps $\partial \hat{v}_{1,\overline{M}_B}$ and $\partial \hat{v}_{1,Z_B}$. Counting dimensions, one sees that

- each $D_i$ is disjoint from the image $\partial \hat{v}(\partial \tilde{Z}) \subset \partial \hat{v}(\partial \overline{M})$, and
- we can choose a submanifold $D$ representing the class $\hat{v}_*(\overline{M}_{g,n}(D,d)[^\text{vir} \cap e(\hat{Ob})])$ that is disjoint from $D_i \cap \partial \hat{v}(\partial \overline{M})$ for all $i$. 

Hence, by shrinking the neighborhood $U$ of $\hat{\nu}(\partial M)$ if necessary, we can assume that
\[
(10.12) \quad U \cap \hat{\nu}(Z) \cap D_i = \emptyset \quad \text{and} \quad U \cap D \cap D_i = \emptyset
\]
for all $i$. Now, consider the commutative diagram:
\[
\begin{array}{ccc}
H_{2\beta+2n}(\text{Map}_D) & \xrightarrow{j_*} & H_{2\beta+2n}(\text{Map}_D, \hat{U}) \\
\downarrow \hat{\nu}_* & & \downarrow \hat{\nu}_* \\
H_{2\beta+2n}(Y_D) & \xrightarrow{k_*} & H_{2\beta+2n}(Y_D, \hat{U}).
\end{array}
\]

Observe that (10.12) implies that for all $i$
\[
(10.13) \quad (a) \ [D] \cdot [D_i] = k_*[D] \cdot k_*[D_i] \quad \text{and} \quad (b) \ [\hat{\nu}(Z)] \cdot [D_i] = \hat{\nu}_* \circ i_*(\{\hat{Z}_U\}) \cdot k_*[D_i]
\]
where, in both of these equations, the dot on the right-hand side is the intersection pairing in $H_{2\beta+2n}(Y_D, \hat{U}) \cong H_{2\beta+2n}(Y_D/U, \partial U)$. By the definition of $\mathcal{D}$, (10.14a) states that
\[
\hat{\nu}_*([\mathcal{M}_{g,n}(D, d)]^\text{vir} \cap e(\mathcal{O}b)) \cdot [D_i] = k_* \circ \hat{\nu}_*([\mathcal{M}_{g,n}(D, d)]^\text{vir} \cap e(\mathcal{O}b)) \cdot k_*[D_i].
\]
But the intersection on the right is, by the commutativity of the diagram, (10.9) and (10.14b),
\[
\hat{\nu}_* \circ j_*([\mathcal{M}_{g,n}(D, d)]^\text{vir} \cap e(\mathcal{O}b)) \cdot k_*[D_i] = \hat{\nu}_* \circ i_*(\{\hat{Z}_U\}) \cdot k_*[D_i]
\]
\[
= [\hat{\nu}(Z)] \cdot [D_i].
\]
This shows $\hat{\nu}_*([\mathcal{M}_{g,n}(D, d)]^\text{vir} \cap e(\mathcal{O}b)) = [\hat{\nu}(Z)]$ and hence, together with (10.8), completes the proof of the Main Theorem (10.1). \hfill \square

**11. Secondary index invariants.** This section puts the obstruction bundle in a general context and explains why Euler class $e(\mathcal{O}b)$ cannot in general be computed using Grothendieck-Riemann-Roch or the Families Index theorems.

Let $E$ and $F$ be Banach vector bundles over a compact parameter space $X$. We can consider the vector bundle
\[
\text{Fred}_\ell(E, F)
\]
\[
\downarrow
\]
\[
X
\]
whose fiber over \( x \in X \) is the space of real linear Fredholm maps from \( E_x \) to \( F_x \) with index \(-\ell \leq 0\). A section \( L \) of \( \text{Fred}_\ell(E, F) \) then defines a family-index class
\[
\text{ind } L \in KR(X)
\]

obtained by pulling back the class of the virtual bundle \([\ker L] - [\operatorname{coker} L]\) on \( \text{Fred}_\ell(E, F) \). The index theorem for families [AS] gives formulas for the Pontryagin classes \( p_i(\text{ind } L) \). But the Euler class does not factor through \( K\)-theory, and hence \( e(\text{ind } L) \) is not computable in the same way and in fact is not even defined in general.

In this context, for each \( k > 0 \), the set \( A_{k, \ell} \) of all \( L \in \text{Fred}_\ell(E, F) \) with \( \dim \ker L = k \) and \( \dim \operatorname{coker} L = k + \ell \) is a submanifold of real codimension \( k(k + \ell) \). As shown in [K], the closures \( \overline{A}_{k, \ell} \) of these submanifolds define “Koschorke classes”
\[
(11.1) \kappa_{k, \ell} \in H^{k(k + \ell)}(\text{Fred}_\ell(E, F)).
\]

A section \( L \) of \( \text{Fred}_\ell(E, F) \) then defines cohomology classes \( L^* \kappa_{k, \ell} \in H^{k(k + \ell)}(X) \). The classes \( \{L^* \kappa_{k+i, \ell} | i > 0\} \) are the obstructions to deforming \( L \) within its homotopy class to a family \( \{L_x\} \) of operators with \( \dim \ker L_x \leq k \) for all \( x \in X \). In particular, when all Koschorke classes \( \{L^* \kappa_{k, \ell}\} \) vanish, \( L \) can be deformed to a section \( \overline{L} \) with \( \ker \overline{L}_x = 0 \) for all \( x \in X \); \( \operatorname{coker} \overline{L} \) is then a rank \( \ell \) vector bundle over \( X \) that represents \( \text{ind } L \in KR(X) \). In this sense, the Koschorke classes are the obstruction to realizing the family index—which is defined as a formal difference of bundles—as an actual vector bundle. Furthermore, when the Koschorke classes vanish this bundle is well-defined up to homotopy and hence, assuming \( \text{ind } L \) is an oriented bundle, the Euler class
\[
e(\text{ind } L) \in H^\ell(X)
\]
is defined. This is a “secondary class” in the sense that it exists only for families with vanishing Koschorke classes.

Now consider the situation at hand, where \( X = \overline{\mathcal{M}}_{g,n}(D, d) \subset \mathcal{M}ap_{g,n}(N_D, d) \), \( E \) and \( F \) are the bundles \( \mathcal{E} \) and \( \mathcal{F} \) defined in Section 5, and \( L \) is the linearization map \( f \mapsto L_f \) with index \(-\ell = -2\beta\). Then (except for the complication described below)
\[
\bullet \ L^* \kappa_{k, 2\beta} = 0 \text{ for all } k > 0 \text{ by the Vanishing Theorem 4.2.}
\]
This gives a global perspective on the role of Theorem 4.2: it ensures that all Koschorke classes vanish. In fact, it shows that after perturbing the Kähler structure \( J \) to \( J_\alpha \), the space of \( J_\alpha \)-holomorphic maps is mapped by \( \Psi(f) = L_f \) into a region in \( \text{Fred}_\ell(\mathcal{E}, \mathcal{F}) \) where the index bundle is an actual bundle. The pullback \( \Psi^*(\text{ind } L) \) is the obstruction bundle \( \text{Ob} \) of the Main Theorem.

Now the complication: while the above paragraph provides valuable intuition, it is not rigorous until one prove that \( \mathcal{E} \) and \( \mathcal{F} \) are locally trivial bundles, or that the
map $L : \mathcal{E} \to \mathcal{F}$ is homotopy equivalent to a map $L' : \mathcal{E}' \to \mathcal{F}'$ between vector bundles with isomorphisms $\text{ker } L \cong \text{ker } L'$ and $\text{coker } L \cong \text{coker } L'$ for each map in the moduli space. It would be interesting to directly establish this general Koschorke picture.

Our proof of the Main Theorem in Section 10 used the fact that the obstruction bundle carries a canonical orientation. The proof, which we give now, fits into the above discussion of the space of Fredholm operators. Below, we write $\overline{M}$ for $\overline{M}_{g,n}(D,d)$.

**Lemma 11.1.** The bundle $\mathcal{O}b$ is orientable and has a canonical orientation.

*Proof.* The linearization $f \mapsto L_f$ defines a map $L : \overline{M} \to \text{Fred}$ whose image lies in the set of Fredholm operators with trivial kernel. Over this set, $\mathcal{O}b$—whose fiber is the cokernel—is isomorphic to the dual of the index bundle. The obstruction to orientability is therefore the pullback $w = L^* w_1(\det L) \in H^2(\overline{M}, \mathbb{Z}_2)$ of the first Stiefel-Whitney class of the real determinant of the index bundle. But the map $L$ extends canonically to a homotopy $\overline{M} \times [0,1] \to \text{Fred}$ by writing $L_f = \overline{\partial} + t R_\alpha$ and setting $L_t(f) = \overline{\partial} + t R_\alpha$. Because $\det L$ is defined over the entire space of Fredholm operators, we have $w = L_0^* w_1(\det L)$. This is zero because the image of $L_0$ consists of complex Fredholm operators, whose kernel and cokernels have canonical complex orientations.

This shows, in fact, that the orientation bundle $\Lambda^{\text{top}} \mathcal{O}b$ is trivial over $\overline{M} \times [0,1]$. There are therefore two orientation classes (nowhere-vanishing sections modulo multiplication by positive functions). The one that agrees with the complex orientation along $\overline{M} \times \{0\}$ will be called the "canonical" orientation on $\mathcal{O}b$. □

Finally, we must specify the orientation on $\mathcal{O}b$ for which the Main Theorem holds. Let $\mathcal{Z}$ be the zero set of a transverse section $\mathcal{O}b \to \overline{M}$. At each $(C, f) \in \mathcal{Z}$, the standard orientations of $\overline{M}$ and $\mathcal{Z}$ used in GW theory are given by the determinant bundles $\det(\overline{\partial}^T \oplus J df)$ and $\det(\overline{\partial}^T \oplus \overline{\partial} \oplus J df)$ respectively. Thus in the equality (0.5) in the Main Theorem, the cycles representing the two sides are consistently oriented provided

$$\det (\overline{\partial}^T \oplus J df) = \det (\overline{\partial}^T \oplus \overline{\partial} \oplus J df) \otimes \Lambda^{\text{top}} \mathcal{O}b$$

This equality holds since the canonical orientation defined in the proof of Lemma 11.1 is

$$\Lambda^{\text{top}} \mathcal{O}b = \det(\overline{\partial})^*.$$ 

12. Remarks on calculating Euler classes. We conclude with some remarks on calculating the Euler class of the obstruction bundle. Algebraic geometers have a standard procedure for calculating the Euler class of the index bundles
of families of $\overline{\partial}$ operators by using the Grothendieck-Riemann-Roch formula, often in conjunction with localization by a group action. This procedure is not, in general, applicable to finding the Euler class of the real bundle $\mathcal{O}b$. But it is worth noting that the GRR formula yields some information in the following two cases.

(1) Since the square of the Euler class is the top Pontryagin class, we have $e^2(\mathcal{O}b) = p_\beta(\mathcal{O}b) = (-1)^{\beta}(\mathcal{O}b \otimes_R \mathbb{C})$. But $\mathcal{O}b \otimes_R \mathbb{C}$ is the complex index bundle $\text{ind}_\mathbb{C}L$ because ker $L$ vanishes for all operators in the family. Thus the GRR formula is applicable for finding $e^2(\mathcal{O}b)$, but not for finding $e(\mathcal{O}b)$ itself.

(2) Recall Givental’s notion of twisted GW invariants: each bundle $E$ over $X$, determines a virtual bundle $E \to M_{g,n}(X,A)$ over the space of stable maps whose fiber over a map $f: C \to X$ is $H^0(C, f^*E) \oplus H^1(C, f^*E)$. The corresponding twisted invariants are obtained by evaluating Chern classes of $E$, together with $\tau$ classes, on the virtual fundamental class. In some especially simple situations, the Euler class of the obstruction bundle can be expressed in terms of twisted GW invariants, and these can be calculated.

**Lemma 12.1.** Over the space of $J_\alpha$-holomorphic maps into $N_D$ there is a locally trivial complex vector bundle $Q$ that is isomorphic to the obstruction bundle $\mathcal{O}b$ as an unoriented real vector bundle, such that for each $J_\alpha$-holomorphic map $f$ the fiber $Q_f$ of $Q$ fits into the split exact sequence of complex vector spaces

$$0 \longrightarrow \ker \overline{\partial}_f \overset{R_\alpha}{\longrightarrow} \text{coker} \overline{\partial}_f \longrightarrow Q_f \longrightarrow 0 \quad (12.1)$$

where $R_\alpha$ is as in (4.3) and where $\overline{\partial}_f$ is an operator on $f^*N$ between the unweighted Sobolev spaces $L^{1,2}(E_f)$ and $L^2(F_f)$ defined in Lemma 7.8.

**Proof.** We will repeatedly use the facts that $R_\alpha$ satisfies $JR_\alpha = -R_\alpha J$ and

$$\langle \overline{\partial}_f \xi_1, R_\alpha \xi_2 \rangle = -\langle R_\alpha \xi_1, \overline{\partial}_f \xi_2 \rangle \quad (12.2)$$

where $\langle \cdot, \cdot \rangle$ denote the standard, unweighted, $L^2$ inner product (cf. [LP, Section 8]). Fix a $J_\alpha$-holomorphic map $f: C \to N_D$ and write $\overline{\partial}_f$ as $\overline{\partial}$. Regard coker $\overline{\partial}$ as the $L^2$ orthogonal complement to the image of $\overline{\partial}$. First note that if $\xi \in \ker \overline{\partial}$ then by (12.2)

$$\langle \overline{\partial}_f \xi', R_\alpha \xi \rangle = -\langle R_\alpha \xi', \overline{\partial}_f \xi \rangle = 0$$

for all $\xi' \in \Omega^0(f^*N)$. Hence $R_\alpha \xi$ lies in coker $\overline{\partial}$. Defining $Q$ to be the $L^2$ perpendicular

$$Q = (R_\alpha (\ker \overline{\partial}))^\perp \subset \text{coker} \overline{\partial}$$

gives the exact sequence (12.1) of complex vector spaces. Note that $R_\alpha$, originally complex anti-linear, becomes complex linear when we reverse the complex structure on ker $\overline{\partial}$ and that this definition of $Q$ splits the sequence.
Next, regard coker($\overline{\partial} + R_\alpha$) as the $L^2$ orthogonal complement to the image of $\overline{\partial} + R_\alpha$ and let $q : \text{coker}^{\overline{\partial} + R_\alpha} \rightarrow \text{coker} \overline{\partial}$ be the $L^2$ orthogonal projection. Observe:

- $q$ is injective: any $\eta \in \text{coker}^{\overline{\partial} + R_\alpha}$ with $q(\eta) = 0$ has the form $\eta = \overline{\partial}\xi$ for some $\xi$, and hence vanishes because, by (12.2),
  \[ 0 = \langle \overline{\partial}\xi, (\overline{\partial} + R_\alpha)\xi \rangle = \|\overline{\partial}\xi\|^2 = \|\eta\|^2. \]
- The image of $q$ lies in $Q$: for any $\eta \in \text{coker}^{\overline{\partial} + R_\alpha}$ and $\xi \in \ker \overline{\partial}$ we have
  \[ 0 = \langle \eta, (\overline{\partial} + R_\alpha)\xi \rangle = \langle \eta, R_\alpha\xi \rangle = \langle q(\eta), R_\alpha\xi \rangle \]
  (the last equality holds because $R_\alpha\xi \in \ker \overline{\partial}$ as above). Thus $q(\eta)$ is $L^2$ perpendicular to the image of $R_\alpha$.

Now count dimensions. From (12.1) we have $\dim Q_f = -\text{index}\overline{\partial} = -\text{index}(\overline{\partial} + R_\alpha) = -2\beta$. But $\ker (\overline{\partial} + R_\alpha) = 0$ by Theorem 4.2, so $\dim Q_f = \dim \text{coker}[\overline{\partial} + R_\alpha]$. Thus $q$ is an isomorphism between $\ker(\overline{\partial} + R_\alpha)$ and $Q$.

Finally, to relate $Q$ to the (locally trivial) obstruction bundle, consider the $L^2$ perpendicular projection $\pi : \mathcal{O}b \rightarrow \text{coker}(\overline{\partial} + R_\alpha) \cong Q$. Suppose that $v \in \mathcal{O}b$ satisfies $\pi(v) = 0$. Then there is an $\xi \in L^{1,2}(E_f)$ with $(\overline{\partial} + R_\alpha)\xi = v$. Since $v$ and $f$ are smooth, elliptic regularity implies that $\xi$ is smooth, so lies in the weighted space $E_f$ for any $p \geq 2$. This contradicts Theorem 8.1 unless $v = 0$. Thus $\pi$ is injective, and therefore an isomorphism because both have dimension $2\beta$. \qed

As $f$ varies across the spaces $\overline{\mathcal{M}} = \mathcal{M}_{g,n}(D, d)$ of $J_\alpha$-holomorphic maps, one obtains families
\[ \ker \overline{\partial} \longrightarrow \overline{\mathcal{M}} \quad \text{and} \quad \text{coker} \overline{\partial} \longrightarrow \overline{\mathcal{M}} \]
whose fibers are the complex vector spaces $\ker \overline{\partial}_f = H^0(f^*N)$ and $\text{coker} \overline{\partial}_f = H^1(f^*N)$. In general, the dimensions of these fibers are not constant: the dimension of the kernel and the cokernel jumps up (by equal amounts) along a “jumping locus” in $\overline{\mathcal{M}}$. But away from the jumping locus Lemma 12.1 gives a formula, due to Kiem and Li [KL], for the Euler class of the obstruction bundle:

**Proposition 12.2.** Suppose $\ker \overline{\partial}$ and $\text{coker} \overline{\partial}$ are locally trivial vector bundles over a set $Z \subset \overline{\mathcal{M}}$. Then there is an isomorphism of oriented real vector bundles
\[(12.3) \quad \mathcal{O}b \cong (-1)^{h_i} Q \]
over each component $Z_i$ of $Z$ where $h_i$ is $h^0(f^*N)$ on $Z_i$. Consequently, $e(\mathcal{O}b) \in H^{2\beta}(Z)$ is
\[(12.4) \quad e(\mathcal{O}b) = \sum (-1)^{h_i} c_\beta \left( \frac{\text{coker} \overline{\partial}|_{Z_i}}{\ker \overline{\partial}|_{Z_i}} \right) \]
where $2\beta = -\text{index}\overline{\partial}$ and the sum is over all connected components $Z_i$ of $Z$. 

Proof. $Q$ has a complex orientation from (12.1) and the orientation of $\text{coker}(\overline{\partial} + R_\alpha) = \mathcal{O} b$ is given by $\det(\overline{\partial})^*$ as in Lemma 11.1. These are related by

$$\det(\overline{\partial})^* = \wedge^{\text{top}} \text{coker} \overline{\partial} \otimes \wedge^{\text{top}} \text{ker} \overline{\partial}$$

(12.5)

$$= (-1)^{h_0} \wedge^{\text{top}} \text{coker} \overline{\partial} \otimes \wedge^{\text{top}} \text{ker} \overline{\partial}$$

$$= (-1)^{h_0} \det Q,$$

which gives (12.3). Taking Euler classes and noting that $Q$ is a complex bundle, we have $e(\mathcal{O} b) = (-1)^{h_1} c_\beta(Q)$ and (12.4) follows from the exact sequence of Lemma 12.1.

Example 12.3. Suppose that $D$ is an elliptic curve with odd theta characteristic. Because the local GW invariants depend only on the parity of the theta characteristic, we can take $N$ to be a trivial bundle. Then $\text{ker} \overline{\partial}$ is the trivial line bundle $\mathbb{C}$ over $\mathcal{M}$. In this case, we have

$$e(\mathcal{O} b) = -c_\beta \left( [\text{coker} \overline{\partial}] - [\mathbb{C}] \right) = -c_\beta (\text{coker} \overline{\partial}) = c_\beta \left( \text{ind}_{\mathbb{C}} \overline{\partial} \right)$$

(12.6)

where $2\beta = -\text{index} \overline{\partial}$ and where $\text{ind}_{\mathbb{C}} \overline{\partial}$ is the complex index bundle.

The formula (12.6) shows that, in this case, the local GW invariants are special cases of Giventhal’s twisted GW invariants of curves. These can be explicitly computed using the result of Proposition 2 in the paper of Faber and Pandharipande [FP].
