**Abstract**

The sinistral *Camaena* species are mainly distributed in southern China and northern Vietnam. There is a total of eight species or subspecies of sinistral *Camaena* recorded at present. By systematically collecting specimens in Guangdong, Guangxi and Yunnan in southern China and the northern areas in Vietnam, two new species, *Camaena lingyunensis* Zhou & Lin, sp. n. and *Camaena detianensis* Zhou & Lin, sp. n. have been discovered. These new species are here characterised based on the comparison of shells, their reproductive system, the molecular phylogenetic analyses of the mitochondrial genes COI and 16S, and the nuclear gene ITS2. Detailed descriptions of the morphological characters, the DNA sequences, and the habitat of the two new species are given. Differential comparisons with related species are provided as well as a key to the sinistral species of *Camaena*.

**Keywords**

*Camaena detianensis* sp. n., *Camaena lingyunensis* sp. n., camaenid species, molecular phylogeny, taxonomy
Introduction

The genus *Camaena*, which contains large dextral or sinistral shell, was established in 1850 by Albers, with the type species *Helix cicatricosa* Müller, 1774. The common features of shell include a large protoconch, a scar-like protuberance or malleation on surface, tawny colouring, and multiple red or brown spiral bands.

The classification of this genus is confused historically, which is especially true for *Camaena cicatricosa* (Müller, 1774) in the sinistral group. Most taxonomists divided the sinistral group, which is distributed in southern China and northern Vietnam into three species, *C. cicatricosa*, *C. habni* (Mabille, 1887), and *C. seraphinica* (Heude, 1890). The taxonomic statuses of *C. habni* and *C. seraphinica* are relatively stable. *Camaena habni* contained two subspecies, *C. h. habni* and *C. habni broti* (Dautzenberg & d’Hamonville, 1887). Some scholars considered *C. habni broti* as a synonym of *C. habni* (e.g. Pilsbry 1891). The classification of *C. cicatricosa* is most confused, and different western scholars divided it into five distinct subspecies or variations on the basis of diverse shell, *C. c. cicatricosa*, *C. c. ducalis* (Ancey, 1885), *C. c. inflata* (Möllendorff, 1885), *C. c. obtecta* (Fischer, 1898), and *C. c. connectens* (Dautzenberg & Fischer, 1906). However, due to lack of fresh specimens, further research on the histological anatomy and molecular biology have not been done. The taxonomic status of the sinistral group has always been controversial, and scientific names have been revised repeatedly. Previously, the Chinese scholars disagreed with this classification, and the name *C. cicatricosa* was used (e.g. Chen and Gao 1987). Ding et al. (2016) clarified the phylogenetic relationships and taxonomic status of the sinistral group with the help of comparative shell morphology, genital anatomy, and molecular phylogeny, and recognised it to contain four species, *C. cicatricosa*, *C. inflata* (Möllendorff, 1885), *C. obtecta* (Fischer, 1898) and *C. connectens* (Dautzenberg & Fischer, 1906). In addition, they described one new species *C. poyuensis* (Zhou, Wang & Ding, 2016). Thus, the number of species within the sinistral *Camaena* group now reached eight species or subspecies.

On the basis of the above work, the authors have studied a large number of specimens collected in Guangdong, Guangxi and Yunnan in southern China and the northern areas in Vietnam during 2013–2016, and discovered two new species according to shell morphology, reproductive system, and molecular biology. The details including morphological characteristics, DNA sequences, and habitat of these two new species are described herein.

Material and methods

This study is based on material collected by the authors from several sites in China (Fig. 1). The longitude and latitude were recorded using a GPS. The live adults were drowned in water for 12–24 hours, and then killed in hot water. Soft body parts were preserved in 75% or 95% ethanol and stored at -20°C. Empty shells were cleaned and preserved at room temperature. Samples have been deposited in the State Key Laboratory of Molluscan Quarantine and Identification, FJIQBC.
Descriptions of two new species of the genus Camaena from Guangxi, China

Figure 1. Map of locations of Camaena species. C. lingyunensis sp. n.: A Kasuo, Lingyun, Guangxi, China. C. detianensis sp. n.: B Detian Falls, Daxin, Guangxi, China. C. cicatricosa: C Nanning, Guangxi, China D Guiping, Guangxi, China E Yangchun, Guangdong, China F Gaoming, Canton, Guangdong, China G Yingde, Guangdong, China H Shantou, Guangdong, China. C. obtecta: I Buhaitun, Jinxia, Guangxi, China J Longbang, Jinxia, Guangxi, China K Longo coc tan, Quang-Huyen, Vietnam L Cao Bang, Vietnam (type locality). C. inflata: M Qianlin park, Guiyang, Guizhou, China N Ziyun, Anshun, Guizhou, China. C. connectens: O Tianbao, Malipo, Yunnan, China P Ha Giang, Vietnam (type locality). C. poyuensis: Q Poyue, Bama, Hechi, Guangxi, China. C. seraphinica: R Dingan, Tianlin, Guangxi, China (type locality). C. habni: S Huu Lien Nature Reserve, Lang-Son, Vietnam.

Shells were measured to 0.1 mm using electronic calipers. Standard shell parameters were taken following Kerney and Cameron (1979). All adult specimens of each species were measured. Only sexually matured specimens were dissected for the examination of reproductive system. Genitalia were dissected under a dissecting microscope (ZEISS Stemi 2000); three specimens of each species were dissected. Terminology for reproductive system follows Gómez (2001). All drawings were traced with the aid of a Canon 550D digital camera.

Approximately 0.02–0.04 g of foot muscle tissue was used for DNA extraction. The muscle tissue was bathed in sterile water for 3–6 hours to remove residual alcohol. Genomic DNA was isolated using Qiagen DNeasy Blood & Tissue kit (Qiagen, Beijing) on more than three specimens per species, examined by agarose gel electrophoresis, and stored at -20°C for further use. The partial mitochondrial cytochrome c oxidase subunit 1 (COI) and 16S rRNA (16S), and the internal transcribed spacer 2 (ITS2) region of nuclear ribosomal DNA were amplified by PCR using the primer pairs, reaction systems and amplification conditions listed in Table 1. The PCR products were analysed by 1.2% agarose gel electrophoresis.
Table 1. Primer pairs and PCR conditions used in the analyses of the COI, 16S rRNA, and ITS2 genes of *Camaena*.

| Gene | COI Primer pairs (5’-3’) | Reaction systems | Cycling conditions | Reference |

| ITS2 | FYIT2:CATCGACATCTGAAGGCACAT RYIT2:TCCCAAACAAACCGACTCCT | 25ul Taq PCR MasterMix×2; 1ul each primer; 2ul DNA; 16ul ddH₂O | 94°C: 30s; 94°C: 10s, 55°C: 30s, 72°C: 1min30s, 40 cycles; 72°C: 10min. | Ding et al. 2016 |

After sequencing, raw sequences were proof-read on chromatograms and aligned into contigs using BioEdit 7.2 (Hall 1999). ITS2 sequences were annotated by using HMMer (Eddy 1998) and ITS2 Database (Koetschan et al. 2010). Sequence alignments were generated using ClustalW implemented in MEGA 5 (Tamura et al. 2011). A total of 165 sequences of COI, 16S, and ITS2 were used in this study, 36 sequences of which were newly generated and deposited in GenBank (Table 2), and the rest referenced in Ding et al. (2016). Pairwise p-distances between taxa were calculated using MEGA5. For phylogenetic analysis, the three sequenced data sets were concatenated into one, with a length of 1,619 bp. The concatenated alignment contained 39 unique sequences, which were used for subsequent analysis. Neighbor Joining (NJ), Maximum Parsimony (MP), and Maximum Likelihood (ML) analyses based on COI+16S+ITS2 combined data set were performed using MEGA5 with default settings. *Bradybaena sequiniana* (Heude,1885) and *Cornu aspersum* (Müller, 1774) were used as outgroups. The node support values were assessed by bootstrap resampling (Felsenstein 1985) using 1000 replicates.

Results

Molecular analysis

Molecular analysis was based on DNA sequences of 53 specimens in the genus Camaena from 18 localities. In this study a total of 165 sequences of COI, 16S and ITS2 was used. There were 36 sequences from C. lingyunensis sp. n., C. detianensis sp. n., C. obtecta (Fischer, 1898) (distributed in Longo coc tan, Quang-Huyen, Cao Bang, Vietnam) and C. hahni (distributed in Huu Lien Nature Reserve, Huu Lung, Lang-Son, Vietnam) listed in Table 2. The rest of the sequences and geographical information from five sinistral Camaena (C. cicatricosa, C. obtecta, C. inflata, C. connectens and C. poyuensis), two dextral Camaena (C. menglunensis and C. jingpingensis) and the out-group (Bradybaena sequiniana and Cornu aspersum) were taken from a previous article (Ding et al. 2016). The sequence alignment was based on lengths of 601 bp (COI), 428 bp (16S) and 590 bp (ITS2), respectively.

Inter- and intraspecific P-distances from the three genes of eight species were calculated and listed in Table 3. According to the results of target gene COI, the p-distances between C. lingyunensis sp. n. and other seven sinistral Camaena were 0.098–0.178, and the p-distances between C. detianensis sp. n. and other seven sinistral Camaena were 0.073–0.189. These numbers significantly exceed the interspecific differentiation standard of terrestrial molluscs, the limit of p-distance 0.03 (average 0.03, generally between 0.00–0.06) (Criscione and Köhler 2014).
Figure 2. Maximum Likelihood tree based on analysis of the concatenated dataset of COI, 16S, and ITS2 sequences. Numbers beside nodes indicate bootstrapping support (%) for main clades.

The phylogenetic analysis showed that NJ, MP, and ML trees have the mostly same topological structure, and indicated that phylogenetic analyses in this research was relatively correct and reliable, and can be applied in genetic relationship research.
and systematic classification. The support degree of each species on ML tree (Fig. 2) all reached 100, and eight clades contained described and published species (including 2 dextral species as contrast), and another two clades included two new taxon. In this study, the genus *Camaena* was clearly divided into sinistral and dextral groups. From the tree structure, branch length and comparison of the known species, the phylogenetic tree supported *C. lingyunensis* sp. n. and *C. detianensis* sp. n. as new species. Moreover, the two new species have closer genetic relationship with *C. cicatricosa*, all of three have semi-open or open umbilicus.

*Holotype.* [FJIQBC 19280] Shell height 29.0 mm, shell width 52.5 mm, height of aperture 21.3 mm, width of aperture 27.0 mm, 24 April 2014, collected from the type locality.  
*Paratype.* [FJIQBC 19281–19293] 13 specimens: 2 empty adult shells, 11 live snails including 9 adults and 2 juveniles. Results of adult measurements: shell height 24.0–34.0 (27.40 ± 2.96) mm, width 49.8–59.5 (53.00 ± 2.77) mm, height of aperture 18.0–25.0 (20.75 ± 1.74) mm, width of aperture 22.0–31.0 (26.35 ± 2.57) mm, 24 April 2014, collected from type locality.  
*Type locality.* Kasuo, Lingyun, Guangxi, China (24°17'47.33"N, 106°39'6.53"E).  
*Etymology.* The name of the new species refers type locality.  
*Description.* Shell. Shell sinistral, large, slightly thin, semi-translucent, hard and fragile, flat globose. 4.75 whorls, the upper whors increasing fast and slightly convex. Spire relatively low. Body whorl rapidly expanded, convex, with a weakly obtuse angulated margin at periphery. Shell fawn with countless light chestnut spiral bands. Spiral bands slender and dense below the periphery of body whorl, forming wide area of bands. Growth lines dense and thick on the surface. Apex quite blunt. Growth lines on protoconch visible when using 15× magnification. Suture line shallow. Aperture lunate, slightly descending in front view. Peristome reflected, sharp and white. Columellar lip reflected, slightly covering the umbilicus. Inner lip attached to the body whorl, forming translucent, thin and smooth callus. Umbilicus open and round. The first whorl can be seen through the umbilicus. Hump beside umbilicus absent.  
*Soft body.* Foot hazel. Tentacles darker. White band from the head to the neck.
Table 3. Inter and intraspecific $p$-distances of sinistral *Camaena* species.

**Reproductive system.** Penis slightly swollen, short. Epiphallus long and thick. Penis retractor muscle very slender and long. Flagellum medium length, thick basally, tapering distally. Vas deferens long and thin. Vagina thick and slightly short. Bursa copulatrix oval. Pedunculus of bursa copulatrix quite long, expanded at basal half, while smooth and slender at the end. Inner penial wall supporting transverse, smooth, and dense pilasters proximally and several longitudinal, thin, curly, and widely-spaced pilasters distally. Verge conical and smooth, with eight transverse wrinkles basally. An obvious longitudinal crack on the verge, and six smooth and longitudinal pilasters with wide space in the crack. Verge opens laterally.

**Ecology.** This species was found on limestone in Lingyun county of Guangxi province. It generally inhabits mountaintops with clouds and mists, but cannot be found at the foot of the mountain.

**Remarks.** The key characters of *C. lingyunensis* sp. n. and the other eight sinistral *Camaena* species are presented in an identification key. This species is clearly different from other species, with a more oblate shape, lower spire, thinner and more fragile shell, and lighter colouration. The umbilicus of the new species is fully open, and the first whorl can be seen from the umbilicus, which significantly is distinguished from *C. poyuensis* (Zhou, Wang & Ding, 2016) and *C. obtecta* (Fischer, 1898) without an umbilicus, *C. inflata* and *C. connectens* (Dautzenberg & Fischer, 1906) with a narrow umbilicus, and *C. cicatricosa* and *C. detianensis* sp. n. with a semi-open umbilicus. The new species is similar with another sinistral snail, *C. seraphinica*, which also has a fully open umbilicus, but with a relatively higher and arched spire, wide and beautiful red spiral bands, and colour spots and no forged trace on the surface. Furthermore, the base region colour of the body whorl around the umbilicus is white. Differently, the
Descriptions of two new species of the genus Camaena from Guangxi, China...

Figure 3. Photographs of shells. A Camaena lingyunensis sp. n. (holotype, FJQBC 19280, Kasuo, Lingyun, Guangxi, China) B Camaena detianensis sp. n. (holotype, FJQBC 18472, Detian Falls, Daxin, Guangxi, China) C Camaena hahni (FJQBC 19300, Huu Lien Nature Reserve, Lang-Son, Vietnam) D Camaena cicatricosa (FJQBC 18505, Guiping, Guangxi, China). Scale bars 10 mm.
new species has a flat and low spire with an inconspicuous forged trace, and contains countless slender spiral bands. The base region colour of the body whorl is the same as the shell surface with slender spiral bands.

Some sinistral *Camaena* species have the same features as the new species on penial wall, such as *C. habni*, *C. poyuensis* and *C. inflata* (Ding et al. 2016), while the verge of these species is significantly different from the new species. The surface of verge of *C. habni*, *C. poyuensis* and *C. inflata* all contains transverse or longitudinal microgrooves, but in the new species it is conical and smooth, and does not have any microgrooves except for a longitudinal crack, from which six longitudinal and smooth pilasters can be seen. There are six longitudinal and deep cracks on verge of *C. poyuensis*, but the cracks cannot be riven.

COI gene *p*-distances between this new species and the other seven sinistral species are 0.098–0.178 (Table 3). On phylogenetic tree, *C. lingyunensis* sp. n. is adjacent to *C. cicatricosa* and *C. detianensis* sp. n. However, the shells of the three species were greatly distinct as follows: (1) the fawn shell color of *C. lingyunensis* sp. n. is much lighter than the dark tawny shell color of *C. cicatricosa* and brown shell color *C. detianensis* sp. n. (2) The spire of *C. lingyunensis* sp. n. is low and flat, while the spires of the latter two are relatively high and arched (3) the *C. lingyunensis* sp. n. has countless light chestnut and slender spiral bands on the body whorl while *C. detianensis* sp. n. has no spiral bands (4) the umbilicus of *C. lingyunensis* sp. n. is fully open, while that of the latter two are semi-open.

**Camaena detianensis** Zhou & Lin, sp. n.

Figs 3B, 4B, 5B, Table 3

**Holotype.** [FJ1QBC 18472] Shell height 38.5 mm, shell width 61.4 mm, height of aperture 22.5 mm, width of aperture 26.2 mm, 21 May 2013, collected from the type locality.

**Paratype.** [FJ1QBC 18473–18482] 10 specimens: all live snails including 4 adults and 6 juveniles. Shell height 34.2–40.4 (38.46±2.49) mm, width 55.0–62.5 (59.60±2.41) mm, height of aperture 19.6–23.9 (22.44±1.67) mm, width of aperture 24.2–28.1 (25.86±1.58) mm, 21 May 2013, collected from holotype locality.

**Type locality.** Detian Falls, Daxin, Guangxi, China (22°51’29.54”N, 106°43’13.51”E).

**Etymology.** Named for the type locality, adjective.

**Description.** Shell. Shell sinistral, large, thick, solid, non-transparent and depressed-globular. 5.5 whorls, the front whorls increasing and convex rapidly. Spire arched. Body whorl expanding with an acute carina at periphery and a shallow groove-like depression above and below the carina, obviously near the aperture. Apex quite blunt. Growth lines on protoconch visible when using 15× magnification. Suture line deep. Surface dark brown and slightly red with obvious malleation. Spiral bands absent. The upper part of the periphery of body whorl with countless thick growth lines, convex, and the lower part smooth. Spire ribs below the periphery relatively obvious.
Descriptions of two new species of the genus Camaena from Guangxi, China...

Figure 4. Reproductive system. A Camaena lingyunensis sp. n. (holotype, FJIQBC 19280, Kasuo, Lingyun, Guangxi, China) B Camaena detianensis sp. n. (holotype, FJIQBC 18472, Detian Falls, Daxin, Guangxi, China) C Camaena bahni (FJIQBC 19301, Huu Lien Nature Reserve, Lang-Son, Vietnam) D Camaena cicatricula (FJIQBC 18505, Guiping, Guangxi, China). Abbreviations: V, verge; AG, albumen gland; BC, bursa copulatrix; E, epiphallus; F, flagellum; HD, hermaphroditic duct; P, penis; PR, penis retractor muscle; PBC, pedunculus of bursa copulatrix; VD, vas deferens.

Aperture lunate. Peristome reflected, white and not sharp. Columellar margin reflected. Umbilicus partly covered by reflected columellar lip. Inner lip attached to the body whorl tightly, forming translucent, smooth and thick callus. Umbilicus obvious and round. A hump beside umbilicus absent.

Soft body. Foot and tentacles are dark brown, and the head color is relatively light.

Reproductive system. Penis slightly long, slender and smooth. Epiphallus long and thin. Penis retractor muscle short, wide and flat. Flagellum very slender and long. Va-
gina smooth and slender. Vas deferens slender. Bursa copulatrix oval. Pedunculus of bursa copulatrix quite long, expanded at the base. Inner penial wall supporting several longitudinal, dense, and curly pilasters with narrow space. Verge long conical with many shallow, longitudinal and narrow pilasters. A shallow transverse microgrooves at the apical 1/3, surrounding the verge. A harelip-like crack at the end of verge. Verge opens terminally.

**Ecology.** The species was found on limestone in Daxin county of Guangxi province. It generally lives in primeval forest or forest with a good ecological environment, and cannot be found in gardens near the forest. The population density of this new species in field is relatively low.

**Remarks.** The key characters of *C. detianensis* sp. n. and the other eight sinistral *Camaena* are presented in the identification key. The carina and groove above and below the carina of *C. detianensis* sp. n. are typical features, which are different from other species of *Camaena* except for *C. hahni*. There is no obvious groove-like depression above and below the periphery of *C. hahni*.

The differences of shell between the new species and *C. cicatricosa* were as follows:

1. *C. detianensis* sp. n. is quite large, and the largest width can reach 62.5 mm, while the maximum width of shell of *C. cicatricosa* is less than 50 mm
2. The shell of this species is dark brown without spiral bands, while the shell of *C. cicatricosa* is yellowish brown, and contains many annular spiral bands
3. There is an acute carina at periphery of body whorl of the new species, and groove-like depression above and below the carina, but *C. cicatricosa* has no obvious carina.

The new species has similar appearance with *C. hahni*, both of which have semi-open umbilicus and a distinct carina at periphery of body whorl, but there still exist differences:

1. *C. hahni* is relatively small, and the width of shell of mature specimen is generally between 45.0–47.0 mm. While the new species is very large, and the width of shell is generally between 55.0–62.5 mm
2. Compared to the new species, *C. hahni* has a sharper carina, but there is no obvious groove-like depression above and below the carina
3. The growth lines and spire ribs of *C. hahni* are thicker, and the shell surface is very rough, while that of the new species is relatively finer
4. The new species has thicker callus, while *C. hahni* has thinner callus.

A dissection of reproductive system shows that the pilasters of penis wall and verge shape of *C. detianensis* sp. n. is similar to that of *C. cicatricosa*, both of which have longitudinal and curly pilasters on the penis wall with narrow spaces, and the verge is conical with many longitudinal pilasters, while *C. hahni* has longitudinal and transverse pilasters on the penis wall, and verge is semicircle and small. There is an annular microgroove on verge, and a harelip-like crack at the end of verge in the new species, which is a diagnostic feature differing from other sinistral *Camaena* species.

**COI gene** $p$-distances between this new species and other seven sinistral species were 0.073–0.189 (Table 3). On the phylogenetic tree, this new species and *C. cicatricosa* are mutually sister groups, and $p$-distance of the two species is 0.073–0.086. According to above information, it is reasonable that the species is recognized as a new species (Criscione and Köhler 2014).
Descriptions of two new species of the genus Camaena from Guangxi, China...

Key to the sinistral Camaena species

1  Umbilicus open ................................................................. 2
   – Umbilicus closed ............................................................ 4

2  Completely open umbilicus .............................................. 5
   – Not completely open umbilicus ...................................... 3

3  Semi-open umbilicus and no hump beside the umbilicus .......... 6
   – Narrow umbilicus and a hump beside the umbilicus ............ 8

4  No hump beside the umbilicus; many transverse microgrooves and few longitudinal deep groove on surface of verge.......................... C. poyuensis (Zhou, Wang & Ding, 2016)
   – A hump beside the umbilicus; many irregular curly grooves on surface of verge .......................................................... C. obtecta (Fischer, 1898)

5  No malleation on shell; a wide red band at periphery of body whorl........ C. seraphinica (Heude, 1890)
   – Malleation on shell and countless chestnut slender spiral bands, forming a wide area of bands below periphery of body whorl .... Camaena lingyunensis sp. n.

Figure 5. Ecological photographs of snails. A Camaena lingyunensis sp. n. (Kasuo, Lingyun, Guangxi, China) B Camaena detianensis sp. n. (Detian Falls, Daxin, Guangxi, China) C Camaena baebi (Huu Lien Nature Reserve, Lang-Son, Vietnam) D Camaena cicatricosa (Yangchun, Guangdong, China).
6 Acute carina at periphery of body whorl ......................................................7
– No obvious carina at periphery of body whorl ...............................................7 *Camaena cicatricosa* (Müller, 1774)

7 Shell medium size; no obvious groove-like depression above and below the carina at periphery of body whorl; verge short and semicircle without a hare-lip-like crack .............................................. *Camaena hahni* (Mabille, 1887)
– Shell very large; shallow groove-like depression above and below the carina at periphery of body whorl; verge long and conical with a harelip-like crack..... ................................................................. *Camaena detianensis* sp. n.

8 Shell globose and thick; verge with transverse deep wrinkles basally and dense longitudinal microgrooves apically .......... *C. inflata* (Möllendorff, 1885)
– Shell depressed-globose; verge with longitudinal deep wrinkles only .......... ................................................................. *C. connectens* (Dautzenberg & Fischer, 1906)

**Discussion**

In the present study, two new species of sinistral *Camaena* were identified based on shell structure and colouration, reproductive system morphology, and molecular characteristics. *Camaena lingyunensis* sp. n. can be distinguished from other sinistral camaenids by the flat, thin, fragile, semi-translucent, and light coloured shell, especially the unique flat globose shape. The large shell, thick callus, acute carina at periphery of the body whorl and groove-like depression above and below the carina are key features of *C. detianensis* sp. n.

Genetic distance has been generally used for classification and determination of Camaenidae, such as the Australian camaenid *Kimberleytrachia* (0.055–0.161, Criscione and Köhler 2014), the Japanese camaenid *Luchuhadra* (0.003–0.205, Kameda et al. 2007), and the Taiwanese camaenid *Satsuma* (0.006–0.150, Wu et al. 2008). The *p*-distance between *C. lingyunensis* sp. n. and the other seven sinistral *Camaena* was significant, 0.098–0.178, as well as between *C. detianensis* sp. n. and the other seven sinistral *Camaena*, 0.073–0.189. All attain interspecific differentiation, and molecular phylogenetic analyses also support these two new species.

*Camaena detianensis* sp. n. and *C. cicatricosa* are closer in phylogeny and reproductive system dissection besides the shell morphology. While *C. detianensis* sp. n. and *C. hahni* have the similar shell. *Camaena hahni broti* (Dautzenberg & d’Hamonville, 1887) once was regarded as a subspecies of *C. hahni*, which is distributed in Nuy-Dong-Nay, Lang-Son, Vietnam. Due to the lack of specimens of *C. hahni broti* we did not compare it with the new species. However, from the pictures of syntypes it can be seen that *C. hahni broti* (MNHN-IM-2000-1848) and *C. hahni* (MNHN-IM-2000-1906) have the same size, morphology, and geographical distribution. Actually, Pilsbry considered *C. hahni broti* as a synonym of *C. hahni* in 1891. In the article of Ding et al. (2016), *C. c. ducalis* (Ancey, 1885), a subspecies of *C. cicatricosa*, was not revised due to lack of specimens. In this research, molecular comparison was not
conducted either. According to literature records, *C. c. duca lis* was named based on a single specimen collected from Kouy-Yang-Fou (nowadays Guiyang), Guizhou. No further specimens were confirmed or recorded since its publication. The shell of *C. c. duclalis* (Ancey, 1885) with narrow umbilicus is quite large, shell width is 74 mm, but the maximum sinistral snail *C. detianensis* sp. n. is 62.5 mm. Some scholars have made great efforts to collect *C. c. duca lis* (Ancey, 1885), but failed (Ding et al. 2016). It is possible that this species has died out. On the other hand, *C. seraphinica* demonstrates great differences from the other sinistral *Camaena* by possessing a non-malleated surface, and white shell background with few wide bands; these characters are closer to Bradybaenidae in shell.

During the gradual lifting from the north Vietnam to the mid-west of Guangxi and then the Yunnan-Guizhou Plateau, the biological and geographical climate conditions changed complicatedly. The limestone landform is widely distributed in these areas and the complex environment has provided helpful conditions for life and reproduction of land snails. These areas have become the hot spots in research on biodiversity of land snails, and many new species have been found in recent years (Páll-Gergely et al. 2016; Páll-Gergely et al. 2015; Schileyko 2011; Nordsiegck 2007). In our opinion, as research progresses, more and more new species of *Camaena* will be found in this area. Hence, a phylogenetic research based on morphology and molecular biology of *Camaena* is essential and urgent.

**Acknowledgements**

We sincerely thank professor De-Niu Chen of Institute of Zoology, Chinese Academy of Science, for helpful comments on the manuscript. We are grateful to Dr. R. Janssen of SMF for taking photographs of type specimens; to Muséum national d’Histoire naturelle, Paris, France, for open access to the digitized photograph of type specimens.
