Front. Cell. Infect. Microbiol. 11:783508. doi: 10.3389/fcimb.2021.783508

Enterocytozoon (E.) bieneusi and Cryptosporidium spp. are the most important zoonotic enteric pathogens associated with diarrheal diseases in animals and humans. However, it is still not known whether E. bieneusi and Cryptosporidium spp. are carried by wild rodents in Shanxi, Guangxi, Zhejiang, Shandong, and Inner Mongolia, China. In the present study, a total of 536 feces samples were collected from Rattus (R.) norvegicus, Mus musculus, Spermophilus (S.) dauricus, and Lasiopodomys brandti in six provinces of China, and were detected by PCR amplification of the SSU rRNA gene of Cryptosporidium spp. and ITS gene of E. bieneusi from June 2017 to November 2020. Among 536 wild rodents, 62 (11.6%) and 18 (3.4%) samples were detected as E. bieneusi- and Cryptosporidium spp.-positive, respectively. Differential prevalence rates of E. bieneusi and Cryptosporidium spp. were found in different regions. E. bieneusi was more prevalent in R. norvegicus, whereas Cryptosporidium spp. was more frequently identified in S. dauricus. Sequence analysis indicated that three known Cryptosporidium species/genotypes (Cryptosporidium viatorum, Cryptosporidium felis, and Cryptosporidium spp. rat genotype II/III) and two uncertain Cryptosporidium species (Cryptosporidium sp. novel1 and Cryptosporidium sp. novel2) were present in the investigated wild rodents. Meanwhile, 5 known E. bieneusi genotypes (XJP-II, EbpC, EbpA, D, and NCF7) and 11 novel E. bieneusi genotypes (ZJR1 to ZJR7, GXM1, HLJC1, HLJC2, and SDR1) were also observed. This is the first report for existence of E. bieneusi and Cryptosporidium spp. in wild rodents in Shanxi, Guangxi, Zhejiang, and Shandong, China. The present study also demonstrated the existence of E. bieneusi and Cryptosporidium spp. in S. dauricus worldwide for the first time. This study not only...
INTRODUCTION

The rodents are one of the largest families of mammals. Wild rodents (e.g., wild rats) are the most widely distributed worldwide. They can shed many pathogens (e.g., Enterocytozoon (E.) bieneusi and Cryptosporidium spp.) into the environment due to living in an open environment, thus becoming potential sources for transmission of pathogens to other animals (Deng et al., 2016; Garcia-Livia et al., 2020; Gui et al., 2020). In addition, the rodents have a closed relationship with humans. Thus, many pathogens, including E. bieneusi and Cryptosporidium spp., might be transmitted from rodents to humans. (Garcia-Livia et al., 2020; Gui et al., 2020; Zhao et al., 2020).

E. bieneusi and Cryptosporidium spp. are the common zoonotic enteric pathogens responsible for a majority of parasitic diarrhea diseases worldwide (Qi et al., 2015; Zhang X. et al., 2018; Zhao et al., 2018; Wang S. N. et al., 2020). Both of them can infect humans and a wide variety of animals (e.g., rodents) (Wang et al., 2013; Zhao et al., 2018; Li and Xiao, 2020; Wang S. N. et al., 2020) mainly through water-borne and food-borne routes (Wang et al., 2013; Zhao et al., 2018). In general, healthy people infected with both pathogens are asymptomatic or manifest symptoms of self-limiting diarrhea. However, the infection of E. bieneusi and Cryptosporidium spp. in immunocompromised individuals may cause chronic or life-threatening diarrheas (Wang et al., 2013; Suththikornchai et al., 2021). Owing to their significance in public health, Cryptosporidium spp. and E. bieneusi have been put into Category B Priority Pathogen list by the National Institute of Allergy and Infectious Diseases (NIAID) (NIAID, 2018). Moreover, E. bieneusi is also listed on the Environmental Protection Agency (EPA) microbial contaminant candidate list of concern for waterborne transmission (Didier et al., 2009).

E. bieneusi is consist of more than 500 genotypes, which are classified into 11 groups based on the sequences of the internal transcribed spacer (ITS) region of the rRNA gene (Santin, 2015; Zhang Y. et al., 2018; Zhao et al., 2018; Li W. et al., 2019; Wang S. N. et al., 2020; Abarca et al., 2021). Group 1, identified as zoonotic, is responsible for a vast majority of human infections (Wang S. N. et al., 2020). Groups 2-11 are mainly composed of host-specific or host-adapted genotypes (Guo et al., 2014; Wang S. N. et al., 2020). To date, a total of 36 ITS genotypes of E. bieneusi have been found in rodent species and 15 (Type IV, BEB6, EbPA, EbPC, C, D, H, CZ3, S6, Peru6, Nig7, Peru8, Peru11, Peru16, and PigITS5) were considered as zoonotic genotypes (Danišová et al., 2015; Cama et al., 2007; Sak et al., 2011; Guo et al., 2014; Perec-Matsysiak et al., 2015; Qi et al., 2015; Roellig et al., 2015; Deng et al., 2016).

Cryptosporidium spp. contains more than 100 species/genotypes based on the sequence of the small subunit (SSU) rRNA gene (Feng et al., 2018; Holubová et al., 2019). To date, 38 of them have been identified in humans, whereas only C. hominis and C. parvum were frequently found in humans (Essid et al., 2018; Krumkamp et al., 2021), and the remaining genotypes/species were occasionally observed in humans. Rodents are one of the most important reservoirs of Cryptosporidium spp. More than 30 Cryptosporidium species/genotypes have been identified in rodent species (Zhang X. et al., 2018). Among them, at least ten Cryptosporidium species (including C. parvum, C. andersoni, C. muris, C. wrairi, C. tyzzeri, C. scrofarum, C. ubiquitum, C. hominis, C. suis, and C. meleagridis) and more than 20 Cryptosporidium genotypes, such as ground squirrel genotypes (I-III), rat genotypes (I-IV), deer mouse genotypes (I-IV), chipmunk genotypes II, vole genotype, and mouse genotypes (II, III), have been identified in humans (Bajer et al., 2002; Nakai et al., 2004; Feng et al., 2007; Foo et al., 2007; Kimura et al., 2007; Kvác et al., 2008; Lv et al., 2009; Paparini et al., 2012; Backhans et al., 2013; Murakoshi et al., 2013; Ng-Hublin et al., 2013; Song et al., 2015; Stenger B. et al., 2015; Stenger B. L. et al., 2015; Zhao et al., 2015; Gholipoury et al., 2016; Saki et al., 2016; Danišová et al., 2017; Wang S. N. et al., 2020).

In view of such severe situations, it is essential to investigate the prevalence of E. bieneusi and Cryptosporidium spp. in different rodent species and identify their species/genotypes. However, information regarding Cryptosporidium spp. infection in rodents was limited in China, which was only reported in Microtus fuscus (Qinghai vole) and Ochotona curzoniae (wild plateau pika) in Qinghai (Zhang X. et al., 2018), brown rats (Rattus norvegicus) in Heilongjiang (Li et al., 2016), bamboo rats in Sichuan (Liu et al., 2015), pet chinchillas in Beijing, Henan and Guizhou (Qi et al., 2015), commensal rodents in Henan and Fujian (Zhao et al., 2015), brown rats in Heilongjiang (Zhao et al., 2018), wild, laboratory, and pet rodents in Beijing, Henan, Fujian and Sichuan (Lv et al., 2009), bamboo rats in Guangdong, Hunan, Guangxi, Jiangxi and Hainan (Wei et al., 2019; Li et al., 2020a; Li et al., 2020b), Asian house rats, brown rats, Edward’s long-tailed rats and muridae in Hainan (Zhao et al., 2019). In China, E. bieneusi in rodents has been only reported in Heilongjiang (Zhao et al., 2018), Beijing (Qi et al., 2015), Henan (Qi et al., 2015; Wang J. et al., 2020), Guizhou (Qi et al., 2015), Sichuan (Deng et al., 2016), Shandong (Wang J. et al., 2020), Guangdong (Wang et al., 2019), Hunan (Wang et al., 2019; Gui et al., 2020), Jiangxi (Wang et al., 2019), Chongqing (Wang et al., 2019), Guangxi (Wang et al., 2019), and Hainan (Zhao et al., 2020).

However, it is still not known whether E. bieneusi and Cryptosporidium spp. are carried by wild rodents in Shanxi,
Guangxi, Zhejiang, Shandong, and Inner Mongolia, China. Thus, the present study was performed to estimate the prevalence and genotypes of *E. bieneusi* and *Cryptosporidium* spp. in wild rodents by the molecular biological method.

**MATERIALS AND METHODS**

**Specimen Collection**

A total of 536 feces samples were collected from four rodent species from Daqing City in Heilongjiang (*n* = 41; 39 *S. dauricus*, 2 *R. norvegicus*), Taigu County in Shanxi (*n* = 53, *R. norvegicus*), Nanning City in Guangxi (*n* = 74, *M. musculus*), Weihai City in Shandong (*n* = 227, *R. norvegicus*), Jiaxing City in Zhejiang (*n* = 119, *R. norvegicus*) and Xilingol League in Inner Mongolia (*n* = 22, *L. brandti*), China from June 2017 to November 2020. These rodents were captured by trapping method. The rodents had been euthanized by CO2 inhalation, and then the fresh feces sample (approximately 500 mg) was collected directly from the intestinal and rectal content by *CO2* inhalation, and then the fresh feces sample (approximately 200 mg) was collected directly from the intestinal and rectal content of each rodent, and then was placed into ice boxes and sent to the laboratory. Information regarding sampling time, region, and species was recorded. This study was approved by the Ethics Committee of Qingdao Agricultural University.

**DNA Extraction and PCR Amplification**

Genomic DNA was extracted from fecal sample of approximately 200 mg using the E.Z.N.A.® Stool DNA Kit (Omega Biotek Inc., Norcross, GA, USA) according to the manufacturer’s instructions, and then was stored at -20°C prior to PCR. The prevalence and genotypes of *E. bieneusi* were identified by PCR amplification of the ITS gene according to the previous description (Zhao et al., 2018). *Cryptosporidium* spp. in the fecal samples was confirmed by PCR amplification of the SSU rRNA gene according to the previous report (Zhao et al., 2018). The positive and negative controls were included in each test. The secondary PCR products were observed using UV light after an electrophoretic analysis at a 1.5% agarose gel containing ethidium bromide.

**Sequence and Phylogenetic Analyses**

The positive PCR specimens were sent to Sangon Biotech Company (Shanghai, China) for sequencing. A new PCR product should be sequenced if previously produced sequences had single nucleotide substitutions, insertions or deletions. The nucleotide sequences were aligned and analyzed with reference sequences by using the Clustal X 1.83 program and Basic Local Alignment Search Tool (BLAST) (https://blast.ncbi.nlm.nih.gov/), in order to determine the species/genotypes of *Cryptosporidium* spp. and *E. bieneusi*. The phylogenetic trees were reconstructed with Mega 5.0 using neighbor-joining (NJ) method under Kimura 2-parameter model (1,000 replicates). All nucleotide sequences were deposited in GenBank with accession numbers MT647749 – MT647806 and OK117929 – OK117932 for *E. bieneusi*, and MT561508 – MT561533 for *Cryptosporidium* spp.

**Statistical Analysis**

The statistical analysis for the prevalence of *E. bieneusi* and *Cryptosporidium* in wild rodents from different region, season, sampling year, and species were performed by using χ2 test in SAS version 9.1 (SAS Institute, Cary, NC, USA). The results were considered to be statistically significant when *P* < 0.05. Odds ratios (ORs) and their 95% confidence intervals (95% CIs) were also calculated to compare the magnitude of various risk factors for *E. bieneusi* and *Cryptosporidium* prevalence.

**RESULTS**

**Prevalence of *Cryptosporidium* spp. and *E. bieneusi***

In the present study, 18 out of 536 (3.4%) fecal samples were identified as *Cryptosporidium*-positive (Table 1). The prevalence rates of *Cryptosporidium* in different species of rodents were 15% (6/401) in *R. norvegicus*, 9.5% (7/74) in *M. musculus*, 12.8% (5/39) in *S. dauricus*, and 0% (0/22) in *L. brandti* (Table 1). Moreover, the prevalence of *Cryptosporidium* in different regions ranged from 0% in Inner Mongolia (0/22) and Shandong (0/227) to 12.2% in Heilongjiang (5/41) (Table 1). Furthermore, the prevalence in different collection years ranged from 0% to 12.8% (Table 1). The prevalence of *Cryptosporidium* in rodent feces collected in autumn (3.7%, 12/321) was slightly higher than that in summer (2.8%, 6/215) (Table 1).

Among 536 rodents, 62 samples (11.6%) were detected to be *E. bieneusi*-positive in three rodent species, with 13.3% (53/399) in *R. norvegicus*, 6.8% (5/74) in *M. musculus*, and 9.8% (4/41) in *S. dauricus* (Table 2). The highest prevalence of *E. bieneusi* was found in Shanxi (37.7%, 20/53), and followed by Zhejiang (24.4%, 29/119), Heilongjiang (9.8%, 4/41), Guangxi (6.8%, 5/74), and Shandong (1.4%, 4/227) (Table 2). The prevalence of *E. bieneusi* was 6.8% (5/74), 20.9%, (49/235) 9.8% (4/41), and 1.4% (4/227) in rodents collected in 2017, 2018, 2019, and 2020, respectively (Table 2). The prevalence of *E. bieneusi* in rodents was 22.8% in summer (49/215) and 4.0% in autumn (13/321) was slightly higher than that in summer (2.8%, 6/215) (Table 1).

*E. bieneusi* and *Cryptosporidium* spp. coinfection was found in three wild rodents in this study. All of them were *R. norvegicus* collected in 2018. Two were collected from Zhejiang Province, and the remaining one was collected from Shanxi Province.

**Distribution of *Cryptosporidium* spp. and *E. bieneusi***

*Cryptosporidium* sp. rat genotype II/III, *Cryptosporidium felis*, and *Cryptosporidium viatorum* were identified in the investigated rodents through the analysis of SSU rRNA gene of *Cryptosporidium*. Furthermore, two *Cryptosporidium* genotypes with uncertain species status were observed (Figure 1 and Table 1). *Cryptosporidium* sp. novell and *C. felis* were found in *S. dauricus* in Heilongjiang. *C. viatorum* and *Cryptosporidium* sp. rat genotype II/III were only identified in *M. musculus* in Guangxi. *Cryptosporidium* sp. novell2 was found in three provinces Zhejiang (*R. norvegicus*), Shanxi (*R. norvegicus*), and Guangxi (*M. musculus*) (Table 1).

A total of 16 *E. bieneusi* genotypes were identified in this study, including 5 known genotypes (XJP-II, EbpC, EbpA, D, and NCF7) and 11 novel genotypes (ZIR1 to ZJR7, GXM1, HLJC1,
HLJC2, and SDR1 (Figure 2 and Table 2). Among them, genotype D was found in R. norvegicus in Zhejiang, Shanxi, and Shandong. EbpA was only found in R. norvegicus in Zhejiang and Shanxi, whereas EbpC was identified in Zhejiang (R. norvegicus), Shanxi (R. norvegicus), and Heilongjiang (S. dauricus). Moreover, NCF2 (R. norvegicus in Shandong), XJP-II (R. norvegicus in Shanxi), ZJR1 to ZJR7 (R. norvegicus in Zhejiang), GXM1 (M. musculus in Guangxi), HLJC1 (S. dauricus in Heilongjiang), HLJC2 (S. dauricus in Heilongjiang), and SDR1 (R. norvegicus in Shandong) were only found in one province (Table 2).

**Phylogenetic Relationships of Cryptosporidium spp. and E. bieneusi**

The phylogenetic analysis of various Cryptosporidium species/genotypes showed two uncertain species status and three known species/genotypes (Figure 1). The sequences of Cryptosporidium sp. novel2, including seven Cryptosporidium spp. sequences (isolates 32, 44, 63, 67, 70, 155, and 245), were clustered with Cryptosporidium spp. sequences identified from environmental samples (Figure 1). Five sequences (isolates 202, 205, 211, 231, and 233) were clustered with Cryptosporidium sp. rat genotype II/III in a same clade (Figure 1). Sequences of isolates 251, 261, 263, and 265 (Cryptosporidium sp. novel1) were grouped into a novel separate clade (Figure 1). Sequences of isolates 270 and 200 were clustered with that of C. felis and C. viatorum in a same clade, respectively (Figure 1).

The Neighbor-Joining analysis for sequences of E. bieneusi species/genotypes obtained in this study revealed that 5 known genotypes and 11 novel genotypes (Figure 2). Fourteen genotypes (5 known genotypes and 9 novel genotypes) were...
Furthermore, HLJC2 was grouped in Group 2, and ZJR2 was divided into Group 1, with ZJR7, SDR1, and D in 1a, EbpC, ZJR5, and ZJR1 in 1d, HLJC1, ZJR4, EbpA, XJP-II, and ZJR3 in 1e, NCF2 in 1b, GXM1 in 1i, and ZJR6 in 1j (Figure 2). Furthermore, HLJC2 was grouped in Group 2, and ZJR2 was classified into Group 10 (Figure 2).

**DISCUSSION**

In this study, the total prevalence of *Cryptosporidium* spp. was 3.4% (18/536) in four rodent species (*R. norvegicus*, *M. musculus*, *L. brandti*, and *S. dauricus*), which was consistent with previous reports showing the prevalence rates ranged from 0.8% to 80.0% in a variety of rat species (Feng, 2010; Mirzaghavami et al., 2016; Wei et al., 2019), e.g., 1.5-38.0% in brown rats, 8.0-31.4% in mice, and 0.8-73.0% in voles (Feng, 2010; Wei et al., 2019; Ježková et al., 2021).

The present study found that the prevalence rates of *Cryptosporidium* spp. in *R. norvegicus*, *M. musculus*, *L. brandti*, and *S. dauricus* were 1.5% (6/401), 9.5% (7/74), 0% (0/22), and 12.8% (5/39), respectively with statistical significance (*P* < 0.05). There was a 0.10- (OR = 0.10, 95% CI 0.0-0.36) and 0.71- (OR = 0.71, 95% CI 0.21-2.41) fold increase of *Cryptosporidium* spp. infection risk in *R. norvegicus* (1.5%, 95% CI 0.3-2.7), *M. musculus* (9.5%, 95% CI 2.6-16.3) compared with that in *S. dauricus* (12.8%, 95% CI 24.2-51.2). Furthermore, the prevalence of *E. bieneusi* in rodents varied in different countries, e.g., 87.5% in Peru (Cama et al., 2007), 28.6-42.9% in Poland (Perec-Matysiak et al., 2015), 1.1% in Slovakia (Danišová et al., 2015), 20.0-100% in USA (Roellig et al., 2015). In the present study, the overall *E. bieneusi* prevalence was 11.6% (62/536), with 13.3% (53/399) in *R. norvegicus*, 6.8% (5/74) in *M. musculus*, 9.8% (4/41) in *S. dauricus*, and 0% (0/22) in *L. brandti*. In China, *E. bieneusi* infection has also been reported in many rodent species, such as Bamboo rat (5.1%, 22/435; 15.4%, 18/117) (Wang et al., 2019; Zhao et al., 2020), Brown rat (7.9%, 9/124; 14.3%, 8/58) (Zhang et al., 2018; Zhao et al., 2020), Chinchilla (3.6%, 5/140) (Qi et al., 2015), Indo-Chinese forest rat (9.3%, 5/140) (Qi et al., 2015), Asiatic brush-tailed porcupine (7.5%, 7/36) (Zhao et al., 2020).
white-bellied rat (18.2% 6/33) (Zhao et al., 2020), Lesser rice-feld rat (36.4%, 16/44) (Zhao et al., 2020). Coinfection (n = 3) of \( E. \) bieneusi and Cryptosporidium spp. was also found in the present study. Different susceptibility of different rodent species, different sampling time and sample size, animal age, and animal welfare could affect the prevalence of Cryptosporidium spp. and \( E. \) bieneusi in different rodent species in different regions.

Although Cryptosporidium spp. in rodent feces collected in summer (6/215, 2.8%, 95% CI 0.6-5.0) has a slightly lower prevalence than those collected in autumn (12/321, 3.7%, 95% CI 1.7-5.8), the difference was not significant statistically (\( P = 0.77 \)) (Table 1). Moreover, the temperature and humidity in summer (49/215, 22.8%, 95% CI 17.1-28.4) may be more suitable for the survival of \( E. \) bieneusi oocysts than in autumn (13/321, 4.0%, 95% CI 1.9-6.2), the infection risk of \( E. \) bieneusi had 0.12-fold increase (OR = 0.12, 95% CI 0.06-0.23) in rodent feces collected in autumn (4.0%, 95% CI 1.9-6.2) than that in summer (22.8%, 95% CI 17.1-28.4) in the investigated rodents (Table 2). The investigated rodents were more active in the summer temperature, which might be the other reason for these rodents to be infection and transmission increase. Other ecological factors such as climate, food resources, breeding, physical activity, etc, which might affect the accuracy of prevalence of the two pathogens, should also be investigated in the further study.

More than 30 Cryptosporidium species/genotypes have been identified in rodents. However, only five species/genotypes were identified in this study, including C. viatorum, C. felis, Cryptosporidium sp. rat genotype II/III, Cryptosporidium sp. novel1, and Cryptosporidium sp. novel2. Among them, Cryptosporidium sp. rat genotype II/III, previously reported in rodents (García-Livia et al., 2020; Ježková et al., 2021), was also identified in this study, which was further confirmed that Cryptosporidium sp. rat genotype II/III was one of the prevalent Cryptosporidium genotypes in rodents. Moreover, two uncertain species of Cryptosporidium (Cryptosporidium sp. novel1 and novel2) were also identified in this study. Cryptosporidium sp. novel1 (isolates 251, 261, 263, and 265) was grouped into a new separate clade. Cryptosporidium sp. novel2 (isolates 32, 44, 63, 67, 70, 155, and 245), grouped with Cryptosporidium environmental. The results indicate two new genotypes/species that have clustered a branch in phylogenetic analysis with environmental isolates of Cryptosporidium spp.
One of the reasons that in environmental samples, it is difficult to determine the species and genotype is the simultaneous contamination of several species and genotypes in samples that after sequencing cannot detect a known species or genotype. Unfortunately, other genes such as COWP and HSP70 of the uncertain species have also not been successfully amplified. Thus, the investigation should be continue performed to further confirm whether presence of the two uncertain species of Cryptosporidium in wild rodents. C. viatorum, has been identified in humans (Insulander et al., 2013; Lebbad et al., 2013; Adamu et al., 2014; Ayinmode et al., 2014; De Lucio et al., 2016; Sanchez et al., 2017; Ukwah et al., 2017; Sannella et al., 2019). C. viatorum was first found in travellers who returned to the United Kingdom from the Indian subcontinent, with clinical signs of diarrhea, fever, headache, abdominal pain, nausea, vomiting, and marked weight loss (Elwin et al., 2012). So far, C. viatorum has been documented in the following countries: Bangladesh, Ethiopia, Barbados, Kenya, Colombia, Nigeria, Pakistan, Guatemala, India, and Nepal (Insulander et al., 2013; Lebbad et al., 2013; Adamu et al., 2014; Ayinmode et al., 2014; De Lucio et al., 2016; Sanchez et al., 2017; Ukwah et al., 2017; Sannella et al., 2019). Besides, C. viatorum was also found in China, such as Hainan Province (Leopoldamys edwardsi), Guangdong Province (Berylms bowersi), and Chongqing City (Leopoldamys edwardsi) in China, and in Australia (Rattus lutreolus) (Koehler et al., 2018; Chen et al., 2019; Zhao et al., 2019). C. felis has been widely reported in cats (Jiang et al., 2020), in addition to patients with HIV/AIDS in Peru, Ethiopia, Nigeria, Jamaica, and Portugal (Cama et al., 2003; Jiang et al., 2020). In this study, C. viatorum and C. felis were found in M. musculus and S. dauricus, which was worth for further research, e.g., whether wild rodents are potentially important reservoirs for C. viatorum and C. felis transmission to humans. More importantly, this is the first study showing existence of Cryptosporidium spp. in S. dauricus, which has expanded the host ranges of Cryptosporidium.

At present, more than 400 genotypes of E. bieneusi have been identified, most of which exhibit host specificity (Santin and Fayer, 2011; Wang S. N. et al., 2020). At least 48 genotypes of E. bieneusi infect both human and animals, bringing zoonoses risks (Li and Xiao, 2019). Through phylogenetic analysis, these genotypes were divided into at least 11 groups, e.g., Group 1 to Group 11 (Zhao et al., 2018; Wang et al., 2019; Li J. et al., 2020; Wang J. et al., 2020; Zhao et al., 2020). However, only 5 known genotypes (XJP-II, EbpC, EbpA, D, and NCF7) and 11 novel genotypes (ZIR1 to ZJR7, GXM1, HLJC1, HLJC2, and SDR1) were identified in the present study. Among them, 14 genotypes were clustered into a highly-supported monophyletic clade (Group 1), indicating that these genotypes are human-pathogenic types and may cause infection between humans and rodents, thus becoming a public health significance. This was the first record of E. bieneusi in S. dauricus. Eleven novel genotypes (ZJR1 to ZJR7, GXM1, HLJC1, HLJC2, and SDR1) were recorded in rodents for the first time. Of which, ZJR1, ZJR3, ZJR4, ZJR5, ZJR6, ZJR7, SDR1, HLJC1, and GXM1 were grouped into Group 1 (Figure 2), thus suggesting that rodents (R. norvegicus, M. musculus, and S. dauricus) may play an important role in the transmission of E. bieneusi between rodents and humans. Genotype XJP-II was previously found in pigs in Xinjiang (Li D. F. et al., 2019b), and NCF2 was also identified in farmed foxes (Vulpes lagopus) (Zheng et al., 2016; Ma et al., 2020) and raccoon dogs (Nyctereutes procyonoides) (Xu et al., 2016) in China, Kangaroo in Australia (Zhang Y. et al., 2018). Genotypes EbpC, EbpA, and D were frequently found in humans and in a broad range of animals (Wang et al., 2013; Liu et al., 2017; Qi et al., 2018; Zhang X. X. et al., 2018; Zou et al., 2018; Wang H. et al., 2020; Wang Y. et al., 2020; Yu et al., 2020). The results showed that natural transmission of E. bieneusi among rodents, humans and many other animals may occur. More importantly, the three ITS genotypes were also found in water in China, which should be paid more attention to prevent the water-borne transmission of E. bieneusi (Hu et al., 2014).

Collectively, the present study firstly demonstrated that existence of Cryptosporidium spp. (3.4%, 18/536) and E. bieneusi (11.6%, 62/536) in rodents in Shanxi, Guangxi, and Zhejiang, China. Three known Cryptosporidium species/genotypes (C. viatorum, C. felis, and Cryptosporidium sp. rat genotype II/III), two uncertain Cryptosporidium species/genotypes (Cryptosporidium sp. novell and Cryptosporidium sp. novel2), 5 known E. bieneusi genotypes (XJP-II, EbpC, EbpA, D, and NCF7) and 11 novel E. bieneusi genotypes (ZJR1 to ZJR7, GXM1, HLJC1, HLJC2, and SDR1) were identified in the investigated rodents, suggesting rodents can act as a potential source of human and animal infections. E. bieneusi was more prevalent in R. norvegicus, whereas Cryptosporidium spp. was more frequently identified in S. dauricus. The present study also demonstrated that S. dauricus was the host of E. bieneusi and Cryptosporidium spp. for the first time. This study expanded the host range of these two parasites, which not only provided basic data for distribution of E. bieneusi and Cryptosporidium genotypes/species, but also provided foundation data for the prevention and control of E. bieneusi and Cryptosporidium spp. in China.

**DATA AVAILABILITY STATEMENT**

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found below: https://www.ncbi.
