Learning State-Aware Visual Representations from Audible Interactions

Himangi Mittal¹, Pedro Morgado¹, Unnat Jain², Abhinav Gupta¹

Abstract

We propose a self-supervised algorithm to learn representations from egocentric video data. Recently, significant efforts have been made to capture humans interacting with their own environments as they go about their daily activities. In result, several large egocentric datasets of interaction-rich multi-modal data have emerged. However, learning representations from videos can be challenging. First, given the uncurated nature of long-form continuous videos, learning effective representations require focusing on moments in time when interactions take place. Second, visual representations of daily activities should be sensitive to changes in the state of the environment. However, current successful multi-modal learning frameworks encourage representation invariance over time. To address these challenges, we leverage audio signals to identify moments of likely interactions which are conducive to better learning. We also propose a novel self-supervised objective that learns from audible state changes caused by interactions. We validate these contributions extensively on two large-scale egocentric datasets, EPIC-Kitchens-100 and the recently released Ego4D, and show improvements on several downstream tasks, including action recognition, long-term action anticipation, and object state change classification. Code and pretrained model are available here: https://github.com/HimangiM/RepLAI

1 Introduction

Recent successes in self-supervised learning (SSL) [48, 10, 31, 28] has brought into question the need for human annotations in order to learn strong visual representations. However, current approaches are bottlenecked by the lack of rich data – they learn from static images which lack temporal information and restrict the ability to learn object deformations and state changes. It is clear that we need videos to learn rich representations in self-supervised manner.

Learning representations from videos is however quite challenging. The first challenge is choosing the right SSL loss. Approaches such as [67, 54] have attempted to learn representations that are invariant to object deformations/viewpoints. However, many downstream tasks require representations that are sensitive to these deformations. Another alternative has been to use the multi-modal data [3, 43, 57] and learn representations via audio. But again most of these approaches seek to align audio and visual features in a common space, leading to invariant representations as well. The second challenge is dealing with the fact that current video-based SSL approaches exploit the curated nature of video datasets, such as Kinetics [9]. These approaches are designed to leverage carefully selected clips, displaying a single action or object interaction. This is in contrast to the predominantly untrimmed real-world data characteristic of large egocentric datasets of daily activities. Here, unlike action centric datasets, the most ‘interesting’ or ‘interaction-rich’ clips have NOT been carefully selected by human annotators. Thus, learning from untrimmed video poses a major challenge, as a significant portion of the data does not focus on the concepts we want to learn.

36th Conference on Neural Information Processing Systems (NeurIPS 2022).
In this work, we ask the question, ‘Can we learn meaningful representations from interaction-rich, multi-modal streams of egocentric data?’ Learning from continuous streams of data requires focusing on the right moments when the actual interactions are likely to occur. Consider, for example, the acts of opening a fridge or placing a pan on the stove. Actions like these create clear and consistent sound signatures due to the physical interaction between objects. These moments can be easily detected from audio alone and can be used to target training on interesting portions of the untrimmed videos. We show that even a simple spectrogram-based handcrafted detector is sufficient to identify interesting moments in time, and that representation learning benefits substantially from using them to sample training clips.

But what should the loss be? Prior work on audio-visual correspondence (AVC) [15, 4, 43] uses the natural co-occurrence of sounds and the visual manifestations of their sources as the source of supervision. However, since the AVC objective still favors invariance, the learned representations are not informative of the changes that happen over time (e.g., representations that can distinguish between closed and opened fridge, or vegetables before and after chopping them). To better capture state changes, we introduce a novel audio-visual self-supervised objective, in which audio representations at key moments in time are required to be informative of the change in the corresponding visual representations over time. The intuition behind this objective is that transitions between object states are often marked by characteristic sounds. Thus, models optimized under this objective would associate the distinct sounds not only with the objects themselves (as accomplished with AVC), but also with the transition between two different states of the object.

To this end, we introduce RepLAI – RepLresentation Learning from Audible Interactions, a self-supervised algorithm for representation learning from videos of audible interactions. RepLAI uses the audio signals in two unique ways: (1) to identify moments in time that are conducive to better self-supervised learning and (2) to learn representations that focus on the visual state changes caused by audible interactions. We validate these contributions extensively on two egocentric datasets, EPIC-Kitchens-100 [14] and the recently released Ego4D [27], where we demonstrate the benefits of RepLAI for several downstream tasks, including action recognition, long term action anticipation, and object state change classification.

2 Related Work

Self-supervised learning. Self-supervised learning methods operate on an unlabeled dataset by explicitly defining pretext tasks such as solving jigsaw puzzle [47], patch location prediction [16], inpainting [50], and image rotation [25] prediction. Following these, the next wave of self-supervised methods has been based on contrastive learning that learns representations with the help of data augmentation and instance discrimination [10, 28, 48, 31, 8]. These methods have shown rapid progress in self-supervised learning for images. While these approaches explore the spatial information of images, RepLAI leverages the temporal information of videos.
Video representation learning. Relevant to our proposed approach is self-supervised representation learning for videos where the spatiotemporal pretext tasks are designed such as temporal order prediction [40, 70, 35, 69], predicting motion and appearance statistics [65], pace prediction [66], temporal cycle consistency [18, 68], and video colorization [64]. Contrastive learning has also been widely adopted in the domain of video [55, 29, 32, 57, 71, 30, 22] with impressive results on action recognition tasks. These methods however learn representations that are invariant to spatio-temporal augmentations, such as temporal jittering, and thus are incapable of representing object state changes. Closer to the objective of RepLAI, we include relevant literature on audio-visual representation learning from videos, where the audio stream is additionally utilized.

Audio-visual representation learning. Learning without additional supervision has also been explored in the context of the audio modality with the help of audio-visual correspondence (AVC) [4, 5]. As stated simply, AVC is the binary classification task of predicting if a video clip and a short audio clip correspond with each other or not (details in Sec. 3.4). Similar tasks like temporal synchronization [36, 49] between audio and video, audio classification [6, 3, 11], spatial alignment prediction between audio and 360-degree videos [41], optimal combination of self-supervised tasks [52] have been shown beneficial for learning effective multi-modal video representations. Other works explore contrastive learning for both audio and video modality [43, 51, 42] as a cross-modal instance discrimination task.

Fine-grained video understanding. Real-world videos are often untrimmed in nature and have multiple actions in a single video. Along this line, fine-grained analysis has been studied for videos in the form of a query-response temporal attention mechanism [72], bi-directional RNNs [58], and semi-supervised learning problem [17]. While these works only utilize the visual modality, another line of work has also explored multi-modal fine-grained video understanding as a transformer-based model [34], by exploiting the correspondence between modalities [44], or by exploring how to best combine multiple modalities - audio, visual, and language [2]. In our work, we try to conduct fine-grained video understanding in a self-supervised manner.

Egocentric datasets. Egocentric datasets offer new opportunities to learn from a first-person point of view, where the world is seen through the eyes of an agent. Many egocentric datasets have been developed such as Epic-kitchens [13, 14] which consist of daily activities performed in a kitchen environment, Activities of Daily Living [53], UT Ego [37, 60], the Disney Dataset [20], and the recently released large-scale Ego4D dataset [27] which consists of day-to-day life activities in multiple scenarios such as household, outdoor spaces, workplace, etc. Multiple challenges and downstream tasks have explored for egocentric datasets like action recognition [34, 33, 38], action localization [56], action anticipation [26, 59, 39, 1, 23], human-object interactions [45, 12, 7], parsing social interactions [46], and domain adaptation [44]. In our work, we evaluate the efficiency of the representations learned by our self-supervised approach on the EPIC-Kitchens-100 and Ego4D datasets over multiple downstream tasks.

3 RepLAI

In this section, we detail our approach to learn audio-visual representations from and for interaction-rich egocentric data in a self-supervised manner, i.e., without relying on human annotated labels. Sec. 3.1 provides an overview of RepLAI and motivates the two key contributions of this work – identifying ‘moments of interaction’ (MoI) and learning from ‘audible visual state changes’. Sec. 3.2 details the proposed approach for MoI detection and section Sec. 3.3 explains the proposed self-supervised objective for learning state-aware representations. Sec. 3.4 explains the objective of audio-visual correspondence learning used to train RepLAI. Sec. 3.5 brings both objectives together and includes necessary details for reproducibility.

3.1 Overview

Given a dataset \( \mathcal{D} = \{(v_i, a_i)\}_{i=1}^{N} \) containing \( N \) long (untrimmed) audio-visual streams, our goal is to learn visual and audio encoders, denoted \( f_{V} \) and \( f_{A} \), that can effectively represent egocentric data. An overview of the proposed approach is depicted in Fig. 2. For each sample \((v, a) \in \mathcal{D}\), we search for moments of interaction (MoI) using the audio stream, and extract short audio and visual clips around these MoIs. These trimmed clips are then encoded into a vectorized representation using \( f_{V} \) and \( f_{A} \). The whole system is trained to optimize two self-supervised losses – an audio-visual
correspondence loss $\mathcal{L}_{AVC}$, and a novel self-supervised loss that learns from audible state changes $\mathcal{L}_{ASTC}$.

Why detect moments of interaction (MoI)? Untrimmed video of daily activities often contains long periods without interactions, which aren’t useful for training. Instead, we search for moments in time that are more likely to contain interactions which we refer to as moments of interaction (MoI).

Why learn from audible state changes? Visual representations of daily activities should be informative of the state of the environment and/or objects being interacted with. Moreover, changes in the environment are usually caused by physical interactions, which produce distinct sound signatures. We hypothesize that state-aware representations can be obtained by learning to associate audio with the change of visual representation during a moment of interaction.

3.2 Audio-driven detection of moments of interaction

Audio signals are particularly informative of moments of interaction. To complete day-to-day activities, we physically interact with objects in our environments. These interactions typically produce distinct audio patterns - short bursts of energy that span all frequencies. This is illustrated in Fig. 1, where we visualize the untrimmed visual and audio data of a person performing a series of actions in the kitchen. The audio data is represented as a log mel spectrogram, where the x-axis represents time and y-axis the audio frequency in log-scale. As can be seen, moments of interaction appear in the spectrogram as vertical edges, which can be easily detected. Once detected, short clips around the moments of interaction are collected into a dataset $D_{MoI}$, and used for training.

The remaining question is how to locate the timestamp of such vertical edges? Intuitively, we do this by finding robust local maxima in the total energy (summed over all frequencies) of the spectrogram. Concretely, let $M(t, \omega)$ be the value of the log mel spectrogram of an audio clip at time $t$ and frequency $\omega$. To remove the influence of background noise and overall audio intensity/volume, we compute the z-score normalization of the spectrogram for each frequency independently $\bar{M}(t, \omega) = s(t, \omega) - \mu_\omega \sigma_\omega + \epsilon$, where $\epsilon$ is small constant for numerical stability. Here, $\mu_\omega$ and $\sigma_\omega$ are the mean and standard deviation of $M(t, \omega)$ over time, respectively.\footnote{Specifically, $\mu_\omega = \mathbb{E}_t[M(t, \omega)]$, $\sigma_\omega^2 = \mathbb{E}_t[(M(t, \omega) - \mu_\omega)^2]$, and $\epsilon = 1 e - 5$.} Next, we define moments of interaction as the set of timestamps which are local maxima of $\sum_{\omega} \bar{s}(t, \omega)$ (or peaks for short). Moreover, to avoid weak local maxima that may be caused by the noisy nature of audio signals, we ignore peaks with small prominence (lower than 1)$^2$. For further robustness, when multiple close peaks are found (less than 50ms apart), only the highest prominence peak is kept.

3.3 Learning from audible state changes

Physical interactions often cause both state changes in the environment and distinct audio signals. To leverage this natural co-occurrence, we propose a self-supervised task that seeks to associate the audio with changes in the visual state during a moment of interaction.

\footnote{The prominence of a peak is defined as the difference between the peak value and the minimum value in a small window around it.}
Learning from Audible State Changes

The proposed AStC formulation (Sec. 3.3)

Audio-Visual Correspondence

(b) Audio-visual correspondence (Sec. 3.4)

Figure 3: ReplAI architecture for AStC and AVC tasks. In both cases, short clips are extracted around moments of interaction (MoI). (a). In AStC, the representation of a visual state change $\Delta v_i$ is matched to the corresponding audio $a_t$. (b). AVC seeks to associate audio $a_t$ with the corresponding visual clips $v_t$.

The proposed task is optimized by minimizing a loss with two negative log-likelihood terms: (1) increase the probability of associating the audio with the visual state change in the forward (i.e. correct) direction, (2) decrease the probability of associating the audio with the visual state change in the backward (i.e. incorrect) direction. Consider, for example, the interaction of ‘closing a fridge door’. To optimize for this task, the audio of closing the door should be (1) similar to the visual transition $\text{open door} \rightarrow \text{closed door}$ and (2) dissimilar to the (backwards) transition $\text{closed} \rightarrow \text{open}$. This encourages learning of representations that are informative of object states, making them useful for a variety of egocentric tasks. Specifically, the audible state change (AStC) loss is defined as

$$L_{AStC} = \mathbb{E}_{v_t, a_t \in D_{\text{MoI}}} \left[- \log \left(p_{\text{frwd}}(v_t, a_t)\right) - \log \left(1 - p_{\text{bkwd}}(v_t, a_t)\right)\right].$$

(1)

The probabilities ($p_{\text{frwd}}, p_{\text{bkwd}}$) are computed from cross-modal similarities

$$p_{\text{frwd}}(v_t, a_t) = \sigma \left(\frac{\text{sim} (\Delta v_t^{\text{frwd}}, a_t)}{\tau}\right),$$

(2)

$$p_{\text{bkwd}}(v_t, a_t) = \sigma \left(\frac{\text{sim} (\Delta v_t^{\text{bkwd}}, a_t)}{\tau}\right),$$

(3)

where $\tau = 0.2$ is a temperature hyper-parameter, and $\sigma$ denotes the sigmoid function. For better readability, we absorb the notations for the audio projection MLP head $h^n_A$ and the state change projection MLP head $h^n_{\Delta V}$ within $\text{sim}(\cdot, \cdot)$, but their usage is clearly illustrated in Fig. 3a.

Audio representations ($a_t$) are obtained by encoding the trimmed audio clips $a_t$ via the audio encoder $f_A$ (shared across all objectives). As explained above, $a_t$ is further projected via $h^n_{AStC}$ to a space where similarity to visual state changes is enforced.

State change representations ($\Delta v_t^{\text{frwd}}, \Delta v_t^{\text{bkwd}}$) are computed by considering two non-overlapping visual clips for each moment of interaction $t$, at timestamps $t - \delta$ and $t + \delta$. The two clips, $v_{t-\delta}$ and $v_{t+\delta}$, are encoded via the visual encoder $f_V$ (shared across all tasks) and a projection MLP head $h^n_{AVC}$ (specific to the AStC task). Specifically, we represent forward and backward state changes as

$$\Delta v_t^{\text{frwd}} = h^n_{\Delta V} \circ f_V(v_{t+\delta}) - h^n_{\Delta V} \circ f_V(v_{t-\delta}),$$

(4)

$$\Delta v_t^{\text{bkwd}} = h^n_{\Delta V} \circ f_V(v_{t-\delta}) - h^n_{\Delta V} \circ f_V(v_{t+\delta}).$$

(5)

In summary, optimizing the loss of Eq. 1 not only requires the audio representation $a_t$ to be aligned with representation of the visual change $\Delta v_t^{\text{frwd}}$ that took place, but also to be different from the hypothetical backward state change $\Delta v_t^{\text{bkwd}}$.

3.4 Learning from audio-visual correspondences [15, 4, 43]

Audio-visual correspondence (AVC) is a well-studied self-supervised methodology for learning unimodal audio and visual encoders. The key idea is to bring visual and audio clips into a common feature space, where the representations of audio-visual pairs are aligned. Note that AVC differs from the proposed AStC task, as AVC seeks to associate the audio $a_t$ with the corresponding visual clips $v_t$, as opposed to the change in visual state $\Delta v_t$. As a result, visual representations learned through AVC are biased towards static concepts, while those learned through AStC are more sensitive to dynamic
concepts. Since both types of representations can be useful for egocentric tasks, we further train the visual and audio encoders, \( f_V \) and \( f_A \), for the \( \text{AVC} \) task.

Specifically, consider a dataset of audio-visual pairs \((v_i, a_i)\) with representations \( v_i = f_V(v_i) \) and \( a_i = f_A(a_i) \). In particular, we let \((v_i, a_i)\) be short clips extracted from sample \( i \) around one of the detected moments of interest. Then, following \([43, 61]\), audio-visual correspondence is established by minimizing a cross-modal InfoNCE loss of the form

\[
\mathcal{L}_{\text{AVC}} = E_{v_i, a_i \sim \mathcal{D}} \left[ - \log \frac{e^{\text{sim}(v_i, a_i)/\tau}}{\sum_j e^{\text{sim}(v_i, a_j)/\tau}} - \log \frac{e^{\text{sim}(v_i, a_i)/\tau}}{\sum_j e^{\text{sim}(v_i, a_j)/\tau}} \right],
\]

where \( \tau = 0.07 \) is a temperature hyper-parameter and \( \text{sim}(\cdot, \cdot) \) denotes the cosine similarity. Both terms in Eq. 6 help bring \( v_i \) and \( a_i \) (i.e., the positives) together. The key difference is whether the negative set is composed of audio representations \( a_j \) or visual representations \( v_j \) where \( j \neq i \).

For readability of Eq. 6, we once again absorb the notation for the audio and visual projection MLP heads \( h_A^{\text{AVC}} \) and \( h_V^{\text{AVC}} \) within \( \text{sim}(\cdot, \cdot) \), and illustrate their usage in Fig. 3b. Fig. 3b also shows that we apply the \( \text{AVC} \) loss twice to associate both the visual clips (extracted slightly before and after the moment of interaction \( t \)) to the corresponding audio.

3.5 Training

The audio-visual representation models \( f_A \) and \( f_V \) are trained to minimize both \( \text{AVC} \) and \( \text{ASTC} \) losses

\[
\mathcal{L} = \alpha \mathcal{L}_{\text{AVC}} + (1 - \alpha) \mathcal{L}_{\text{ASTC}}
\]

where \( \alpha \) is a weighting hyper-parameter between the two terms. While we experimented with different values of \( \alpha \), we found that equal weighting produced best results.

Implementation details. We follow prior work on audio visual correspondence \([43]\), and use an R(2+1)D video encoder \([62]\) with depth 18 and a 10-layer 2D CNN as the audio encoder. Two video clips are extracted around moments of interaction at a frame rate of 16 FPS each with a duration of 0.5s, and separated by a gap of 0.2s. Video clips are augmented by random resizing, cropping, and horizontal flipping resulting in clips of 8 frames at a resolution of 112 × 112. As for the audio, we extract clips of 2s at 44.1kHz and downsample them to 16kHz. If the audio is stereo, we average the two waveforms to downgrade to mono, and then convert the mono signal to a log mel spectrogram with 80 frequency bands and 128 temporal frames. Models are trained with stochastic gradient descent for 100 epochs with a batch size of 128 trained over 4 GTX 1080 Ti GPUs, a learning rate of 0.005 and a momentum of 0.9. For Ego4D, we use a batch size of 512 trained over 8 RTX 2080 Ti GPUs with a learning rate of 0.05. The two loss terms in Eq. 7 are equally weighted with \( \alpha = 0.5 \).

4 Experiments

In this section, we demonstrate the benefits of identifying moments of interaction and learning state-aware representations through an audible state-change objective. We also show that, while large scale audio-visual correspondence (AVC) is beneficial, it is not sufficient to learn state-aware representations required for egocentric tasks. The setup used for our experiments is described in Sec. 4.1. Results and discussion of main takeaways are presented in Sec. 4.2.

4.1 Experimental Setup

Datasets. We evaluate on two egocentric datasets: EPIC-Kitchens-100 \([14]\) and Ego4D \([27]\). EPIC-Kitchens-100 contains 100 hours of activities in the kitchen. Ego4D contains 3670 hours of egocentric video covering daily activities in the home, workplace, social settings, etc. For experiments on Ego4D, we use all videos from the Forecasting and Hand-Object interaction subsets.

Baselines and ablations. We consider various baselines as well as ablated versions of RepLAI. Random represents an untrained (randomly initialized) model. AVID \([43]\) and XDC \([3]\) are two state-of-the-art models pre-trained on 2M audio-visual pairs from AudioSet \([24]\) that only leverage audio-visual correspondence. For the full method RepLAI, we initialize the model weights from AVID before training on moments of interaction to minimize both AVC and state change loss, ASTC.

4.2 Discussion of results

As can be seen in Tab. 1 and Tab. 2, RepLAI outperforms all other methods across all downstream tasks. Overall, this can be attributed to its ability to focus on interactions, both by detecting when they occur and by learning representations that are sensitive to interactions. A closer analysis of these results reveals several insights that we discuss next.

RepLAI enhances large-scale AVC driven approaches. Prior work on self-supervised audio-visual learning has shown strong audio-visual representations for action recognition [43, 42]. One question that we seek to answer is, how useful are these representations to egocentric tasks and what are their limitations? To answer this question, we compare our model trained from scratch, RepLAI (Scratch),

---

3Edit distance measures the minimum number of operations required to convert the predicted sequence of actions to ground truth. To account for multi-modality of future actions, it also allows the model to make $Z = 20$ predictions, and only accounts for the best prediction.
with our model using the weights from AVID [43] as initialization for both the visual and audio encoders. We also compare our method to standalone AVID and XDC i.e. without further self-supervised training. Comparing rows (2), (3) and (8) in Tab. 1 and Tab. 2, it is clear that RepLAI enhances large-scale AVC pre-training by significant margins, leading to absolute improvements of 5% in top-1 verb accuracy on EPIC-Kitchens-100, 4.2% on Ego4D, 5.2% increase in state-change classification accuracy, and 5.6% reduction on the edit distance for long-term anticipation compared to AVID. Comparing rows (7) and (8), we also see that large-scale AVID pre-training enhances the representations learned by RepLAI on EPIC-Kitchens-100 significantly but only marginally on Ego-4D. This is likely due to the significantly large diversity of scenes in Ego4D. Thus, while relying on large-scale audio-visual pre-training (as with AVID) can help avoid overfitting on smaller egocentric datasets, this is less critical when training on larger and more diverse data.

**Detecting moments of interaction (MoI) helps representation learning.** We hypothesize that to learn good representations for egocentric data of daily activities, self-supervised learning should focus on moments in time when interactions occur. To assess whether our audio-driven MoI detection algorithm helps representation learning, we compare RepLAI with an ablated version, RepLAI w/o MoI, where the model is trained on audio-visual clips extracted at random from the untrimmed videos. As can be seen by comparing rows (6) and (8) in Tab. 1 and Tab. 2, sampling clips around moments of interactions (which are likely to be aligned with the actual state changes) together provide an information-rich feedback to our model in better understanding how the state changes by an interaction and how the actions transition over time. These results also clearly show that the proposed MoI detection procedure is able to find moments in time that are especially useful for learning representations of daily activities. We emphasize the simplicity and effectiveness of our audio-driven detector, which shows how informative audio can be when searching for moments of interaction. In the future, we believe that learning-based approaches could further enhance MoI detection, and further improve the learned audio-visual representations. We also show several qualitative examples of detected MoI in the supplement.
AVC and AStC are complementary. To assess the impact of both terms in Eq. 7, we evaluate RepLAI trained without $L_{AVC}$ and without $L_{AStC}$. Comparing rows (4), (5) to row (2) and row (3) in Tab. 1 and Tab. 2 shows that each term enhances the representations obtained through large-scale audio-visual pre-training (AVID). Furthermore, comparing the ablated models in rows (4) and (5) to the full model in row (8) shows that these two terms are complementary to each other. This is because the AVC and AStC tasks encourage learning of representations with different characteristics. AVC focuses on learning visual representations that are informative of what kind of sounding objects are present in the video, while AStC forces the model to differentiate between visual representations that occur before and after state change interactions.

RepLAI encourages state-aware representation learning. To study the representations learned by our approach for different states, we generate a t-SNE plot [63] for RepLAI and AVID as shown in Fig. 4. For generating a simpler visualization, a small dataset is prepared consisting of all the videos corresponding to a single participant, $P01$, in EPIC-Kitchens-100 and split into clips of 0.5s. We can observe that there is a larger spread in the t-SNE plot for RepLAI than AVID. A larger spread indicates that the representations of the various states are significantly different from each other and form more distant clusters as shown by RepLAI. Whereas, if the state representations are similar to each other, they are clustered together and show lesser spread as shown by AVID. MoI are the key moments of interactions with an object in an environment where the state is changing. AVID has no such information about the key moments and also does not have an explicit state change objective function. Therefore, it is unable to discriminate between the before and after state of an action and has less effective state-aware information in its representations.

RepLAI representation are more generalizable and robust to long-tail. To assess RepLAI in a scenario with domain shift, we evaluate on unseen participants that were fully excluded from the pre-training of RepLAI. Tab. 3 shows that RepLAI significantly outperforms baselines and ablations, indicating that representation learning by our model provides much better generalization. Moreover, the verb and noun classes in EPIC-Kitchens-100 exhibit a long-tailed distribution. When further compared on head and tail classes separately in Tab. 3, we can observe that RepLAI outperforms all other methods highlighting its higher robustness on a long-tailed distribution.

Self-supervised vs supervised representation learning. Tab. 2 also compares RepLAI to fully supervised methods introduced in Ego4D [27] (rows S1, S2 and S3). We can observe that RepLAI can also perform competitively to the fully supervised approaches when we have access to larger and more diverse data. With further focus on SSL for untrimmed datasets, SSL methods will be able to match supervised approaches, and our work takes a step towards it.
5 Conclusion

In this work, we propose an audio-driven self-supervised method for learning representations of egocentric video of daily activities. We show that in order to learn strong representations for this domain, two important challenges need to be addressed. First, learning should focus on moments of interaction (MoI). Since these moments only occur sporadically in untrimmed video data, we show that MoI detection is an important component of representation learning in untrimmed datasets. Second, learning should focus on the consequences of interactions, i.e., changes in the state of an environment caused by agents interacting with the world. In particular, by seeking to identify visible state changes from the audio alone, we can learn representations that are potentially more aware of the state of the environment and hence, particularly useful for egocentric downstream tasks.

Acknowledgements

We would like to thank DARPA MCS, ONR Young Investigator and DARPA SAIL-ON for the funding.

Broader impact

Deep learning models are capable of learning (and sometimes even amplifying) biases existing in datasets. While several steps have been taken in datasets like Ego4D to increase geographical diversity, we would like to encourage careful consideration of ethical implications when deploying these models. While public datasets are essential to make progress on how to represent visual egocentric data, premature deployment of our models is likely have negative societal impact, as we did not check for the presence or absence of such biases.

Checklist

Please do not modify the questions and only use the provided macros for your answers. Note that the Checklist section does not count towards the page limit. In your paper, please delete this instructions block and only keep the Checklist section heading above along with the questions/answers below.

1. For all authors...
   (a) Do the main claims made in the abstract and introduction accurately reflect the paper’s contributions and scope? [Yes]
   (b) Did you describe the limitations of your work? [Yes] We discuss the limitations after the conclusions section of the main paper along with the potential avenues for future research inspired by the limitations of our method.
   (c) Did you discuss any potential negative societal impacts of your work? [Yes] Refer to the section after the conclusions
   (d) Have you read the ethics review guidelines and ensured that your paper conforms to them? [Yes]

2. If you are including theoretical results...
   (a) Did you state the full set of assumptions of all theoretical results? [N/A]
   (b) Did you include complete proofs of all theoretical results? [N/A]

3. If you ran experiments...
   (a) Did you include the code, data, and instructions needed to reproduce the main experimental results (either in the supplemental material or as a URL)? [Yes] The code and instructions are available publicly.
   (b) Did you specify all the training details (e.g., data splits, hyperparameters, how they were chosen)? [Yes] Refer to Section 3.5: Implementation Details
   (c) Did you report error bars (e.g., with respect to the random seed after running experiments multiple times)? [No] Since the train and test set are too large, it takes a lot of time and resource to run the experiments multiple times. However, errors bars are expected to be small, given their sizes.
   (d) Did you include the total amount of compute and the type of resources used (e.g., type of GPUs, internal cluster, or cloud provider)? [Yes] Refer to Section 3.5: Implementation Details

4. If you are using existing assets (e.g., code, data, models) or curating/releasing new assets...
   (a) If your work uses existing assets, did you cite the creators? [Yes]
   (b) Did you mention the license of the assets? [N/A]
   (c) Did you include any new assets either in the supplemental material or as a URL? [Yes]
   (d) Did you discuss whether and how consent was obtained from people whose data you’re using/curating? [N/A]
   (e) Did you discuss whether the data you are using/curating contains personally identifiable information or offensive content? [N/A]

5. If you used crowdsourcing or conducted research with human subjects...
   (a) Did you include the full text of instructions given to participants and screenshots, if applicable? [N/A]
   (b) Did you describe any potential participant risks, with links to Institutional Review Board (IRB) approvals, if applicable? [N/A]
   (c) Did you include the estimated hourly wage paid to participants and the total amount spent on participant compensation? [N/A]
