ABSTRACT

Delta-Like Non-Canonical Notch Ligand 1 (DLK1) is one of the key genes involved in the development of muscle, liver, pancreas, and lung cells; adipocytes production; and the improvement of digestion, growth performance, and meat quality. It has been documented that fennel is effective in increasing the DLK1 gene expression in the testis, liver, and muscle tissues, which may consequently have important implications for sheep production. Hence, the aim of the current investigation was to evaluate the fennel seed powder's effect on DLK1 expression in testis, liver, and humeral muscle tissues in growing lambs. For the purpose of this study, 30 male Kermani sheep were fed with three different groups of diets (number of animals in each group was 10), including control (without any fennel seed powder), treatment 1 (with 10 g/kg of dry matter (DM) fennel seed powder), and treatment 2 (with 20 g/kg of DM fennel seed powder) during a 3-month period. Thereafter, total RNA was extracted, cDNA was synthesized, and Real-Time PCR was performed. The addition of fennel seed powder (in the treatment 1 and treatment 2 groups) in the growing lambs' diets consequently resulted in greater expression of DLK1 in both the liver and humeral muscle tissues compared to the testis tissue (P < 0.05). Furthermore, the increased DLK1 expression was higher in the tissue of humeral muscle (P < 0.05) in comparison to the other two tissues. Additionally, the concentration of blood testosterone was greater (P < 0.05) for the animals fed with fennel powder compared to growing lambs fed with the control diet. However, the concentrations of liver enzymes, including serum glutamic oxaloacetic transaminase (SGOT) and serum glutamic pyruvic transaminase (SGPT), decreased by the addition of 10 g/kg DM fennel to diets of lambs compared to the control diet (no fennel). Therefore, it can be concluded that using fennel seed powder in the diet of growing lambs can improve the concentrations of blood testosterone, SGOT, SGPT, and muscle structure (increased mass of muscle and size of muscle fiber).

1. Introduction

The Kermani sheep breed is one of the 27 breeds and ecotypes living in Iran, and animal management plays a key role in achieving the optimal genetic and phenotypic characteristics of this breed (Masoudzadeh et al., 2020). The use of phytobiotics and bioactive plants with antimicrobial growth promoters in animal feeding has been suggested to improve zootechnical output variables and to prevent the development of some types of diseases (Ačimović et al., 2016). These plants have several biological properties such as antioxidants, hypocholesterolemic, antimicrobial activity, stimulants of immune system, stress reduction (Lee et al., 2015), and the nutrient digestion improvement (Ačimović et al., 2016). Furthermore, in comparison with other feed additives, another advantage of these plants is their low cost. Hence, the use of these plants in stimulating digestive enzymes and improving liver functions can be considered as a promising step in sheep industry. Carcass yield, feed
conversion ratio, and feed consumption have also been reported to be enhanced in response to the addition of bioactive plants to animals’ diets (Acimović et al., 2016). One of the most important plants with bioactive compounds is fennel (*Foeniculum vulgare*), which belongs to the *Apiaceae* family that has been used by humans since the ancient era. It has been demonstrated that using diets containing fennel for sheep could improve their growth outputs and performance of muscle tissue, thereby resulting in better feed conversion rates (Hajalizadeh et al., 2019).

Delta-Like Non-Canonical Notch Ligand 1 gene (*DLK1*) is also known as a preadipocyte factor 1 (*Pref-1*) or fetal antigen 1 (*FA1*). Accordingly, this gene is expressed in fetal cells, adult adrenal cortex, adrenal gland tumours, and endocrine tissues, and hardly in testicular adrenal rest tumors, fetal Leydig cells, and in a subset of adult Leydig cells (Lottrup et al., 2015). According to the study by Waddell et al. (2010), *DLK1* has a regulative function in different tissues, which is related to terminal differentiation and cell-fate decision of progenitor cells. Moreover, the *DLK1* has dissimilar expression patterns in Leydig cells during their development and its patterns suggest that this gene acts as a marker of progenitors or immature Leydig cells (Lottrup et al., 2015). In another study, Tanimizu et al. (2003) have demonstrated that *DLK1*, which consists of two transmembrane and soluble forms, has a significant task in extension of liver. In addition, Rocha et al. (2007) in their research have observed *DLK1* expression in the liver with lower levels from the maternal allele. Correspondingly, similarly *DLK1* expression patterns in the liver and muscle tissues were reported by in the study by Oczkowski et al. (2010). Moreover, Yevtodiyenko and Schmidt (2006) have shown that *DLK1* is highly expressed in the hepatocytes of the fetal liver on embryonic day 12.5 and down-regulates on embryonic day 16.5. Besides, this gene is expressed in the connective tissue capsule of the liver, but not in the hematopoietic cells of liver, even though these cells constitute more than 50% of liver.

One of the most important phenotypes in sheep is muscle hypertrophy of the hindquarters, also known as “callipyge (CLPG) phenotype”, which does not follow Mendel’s rules. Accordingly, its inheritance is one type of polar overdominance. In this regard, when the offspring inherits the mutated allele from father and the wild type allele from mother, it shows the CLPG phenotype. Previously, *DLK1* has been widely studied in sheep for the diagnosis of the Single Nucleotide Polymorphism (SNP) for the CLPG phenotype (Gockett et al., 1996). Smit et al. (2003) have studied *DLK1* expression in the CLPG phenotype and as a result, they have shown that expression level of *DLK1* enhanced. Due to the important role of *DLK1* in muscle and its association with the CLPG phenotype in sheep, it has been shown that the expression level of *DLK1* enhanced in response to the addition of bioactive plants to animals’ diets (Hajalizadeh et al., 2019). Accordingly, the results of this study showed that enhancing the consumption of fennel in the diet causes a positive effect on the expression of *DLK1* in both the rumen and femur muscle tissues. Thus, *DLK1* can be considered as an interesting candidate gene in farm animals for marker-assisted selection (Yevtodiyenko and Schmidt 2006).

According to previous studies, the effect of fennel and the role of *DLK1* expression on testis, liver, and humeral muscle tissues of livestock, especially sheep, have not been reported in any study up to now. Therefore, in continuous with the previous research (Masoudzadeh et al., 2020) and in order to develop and complete its findings, the current investigation was conducted to investigate the associations among the expression of *DLK1* in humeral muscle, liver, and testis tissues, growth and selected biochemical traits, and fennel feeding in Kermani lamb.

### 2. Materials and methods

#### 2.1. Ethics approval and consent to participate

All the ethical guidelines and native standards were applied for performing the current study in terms of the Iranian Council of Animal Care Guide and Use of Experimental Animals (IACUC Protocol #IR2018011).

#### 2.2. Selection of lambs, rations, and experimental design

Since the current study was conducted to complete and develop the findings of our previous study, the same animals, diets, and experimental design were used (for more information please see the study by Masoudzadeh et al., 2020). After the adaptation period, before the morning feeding, the animals were weighed during a 14-day interval to compute the feed conversion (FC) by dividing total dry matter intake by total weight gain for the interval. Therefore, the mean of daily live weight gain for the animals was calculated by subtracting the initial weight from the final weight during the performance phase period (80 days) as explained in our previous investigation (Masoudzadeh et al., 2020). Different treatments, including zero, 10, and 20 g/kg DM of fennel were used in the diet of sheep for a 90-day duration (Table 1) with 10 animals included in each group. In the present study, the combination of the used basal (control) diet (dry matter basis in %) was as follows: wheat straw, chopped (10%); alfalfa hay, chopped (30%); corn grain, ground (9%); barley grain, ground (28%); wheat bran (13%); soybean meal (8%); vitamin D, E, and A premix (0.6%) (includes 5,000,000 IU of Vitamin D, 500,000 IU of Vitamin E and 5,000,000 IU of Vitamin A per kg); trace-mineralized salt (0.6%) (Containing 20.5% Dynamad, 75.15% NaCl, 3.046% Mn, 0.253% Zinc Salt, 1.025% Cu-sulphate, 0.011% Na-selenide, and 0.015% EDDI-80); sodium bicarbonate (0.5%); and limestone (0.3%) (As described in the study by Masoudzadeh et al., 2020).

#### 2.3. Measurements and analytical methods

Blood samples were collected in 10-mL tubes containing anticoagulant (EDTA) by passing 3 h from the morning feeding on the day before slaughter. Subsequently, the samples were centrifuged at 6000×rpm for 10 min. For further analyses, these obtained samples were frozen at −20 °C. In order to calculate the concentration of serum glutamic oxaloacetic transaminase (SGOT) and serum glutamic pyruvic transaminase (SGPT), an automatic analyzer (Technicon RA 1000; Bayer Co., NY, USA) was used via proper testing kits (Parsazmun Laboratory, Tehran, Iran). ELISA kit (Stat Fax) and testosterone set (Pantagnost-e-Eisar Co, Iran) were used to determine the concentration of serum metabolizable energy (ME) and vitamin A, respectively. The metabolizable energy (ME) was calculated by dividing the total dry matter intake by the animal's dry matter intake; the daily dry matter intake was calculated by subtracting the total dry matter intake from the daily dry matter intake. The expression of *DLK1* was measured by qPCR. The expression levels of *DLK1* were calculated using the Livak method (Livak, 2001). The qPCR primers used in this study were designed as follows:

**Table 1. Chemical analysis and components of fennel (DM basis).**

| Ingredients               | amounts   |
|--------------------------|-----------|
| Dry matter               | 91%       |
| Organic matter           | 87.03%    |
| Crude protein            | 15%       |
| Ether extract            | 9.76%     |
| Metabolizable energy     | 12.12 mega joules per kilo gram |
used for calculating testosterone concentration. All the studied animals were sacrificed immediately after the end of the experiment and tissue sampling was performed from liver, testis, and humeral muscle tissues (270 samples, including 10 animals x 3 groups x 3 tissues x 3 repeats for each tissue) along with recording weights for the testis, gallbladder, before slaughter, back muscle (loin), warm carcass, lean meat, femur (leg) muscle, and eye muscle area (as described in the study by Masoudzadeh et al., 2020).

2.4. Analysis of RNA expression results

For each tissue sample, a real time polymerase chain reaction (RT-PCR) was done as described in our previous investigation (Masoudzadeh et al., 2020). Some specific primers were used for DLK1 and beta actin (ACTB) as applied for the reference gene (internal control) for RT-PCR technique (Table 2) using Rotor-Gene Q MDx device (QIAGEN Hilden, Germany).

Standard methods of AOAC (2000) were used for analyzing nitrogen (method 976.05; Kjeldahl Vap50 Gerhardt, Germany), DM (dry matter), ash (method 942.05; Shimifan F-47, Tehran, Iran) and ether extract (method 920.39; Soxhlet Model 2000 Automatic Gerhardt, Germany). The method of Van Soest et al. (1991) was used to determine the NDF from the diets with 20 g/kg DM fennel powder (control diet). The lambs fed with 20 g/kg DM fennel powder showed the control diet (0 g/kg DM fennel powder). However, the liver weight was lower in the animals fed with 20 g/kg DM fennel powder compared to those fed with the control diet (0 vs 20 g/kg DM fennel powder) (Table 3). The results of blood liver enzymes of SGOT, SGPT, and Testosterone (Table 4) showed that blood testosterone concentration was greater in the animals fed with 10 and 20 g/kg DM fennel powder compared to those fed with the control diet (3.50 and 4.40 vs. 1.70 ng/dl, P < 0.05). It is noteworthy that concentrations of blood liver enzymes SGOT and SGPT only decreased by adding 10 g/kg DM fennel powder to the diet compared to the control animals (P < 0.05). However, no significant difference was found between the animals fed with 20 g/kg DM fennel powder and the lambs fed with 0 g/kg DM fennel powder (control). The results of two-way ANOVA analysis in terms of the comparison of the means among different tissues and different levels of fennel seed powder feeding for DLK1 expression based on LSD test are shown in Tables 5 and 6.

2.5. Statistical analysis

The MIXED procedure of SAS was applied for evaluating the data in the format of the complete randomized design (SAS 2005). Next, in order to examine the normal pattern of the data distribution, the Pair Wise Fixed Reallocation Randomisation Test® was applied (REST, 2009). The LSD test was also performed for comparing the means (P < 0.05). Finally, the results of real time PCR were analyzed via Pfaffl formula and using REST software (Pfaffl et al., 2002).

For assessing the main effect of the level of fennel seed powder and the tissue effect with the fennel x tissue interaction, the following statistical model was used:

\[ X_{ijm} = \mu + \alpha_i + \beta_j + \alpha\beta_{ij} + \epsilon_{im} [\text{ij}] \]

Where \( \epsilon \) shows the main effect of tissue at level i, \( \mu \) shows the mean, \( \beta \) shows the main effect of fennel at level j, \( \epsilon \) shows the effect of all other extraneous variables on subject m in the treatment group \( [\text{ij}] \). \( \alpha\beta \) is the interaction effect of tissue at level i and fennel at level j, and \( X_{ijm} \) shows the dependent variable score for subject m in the treatment group \( [\text{ij}] \) (as defined in our previous investigation; Masoudzadeh et al., 2020).

3. Results

The finest feed conversion (FC) was established in the studied animals fed with 20 g/kg DM fennel powder (P < 0.05). The weights of the testis and gallbladder, and body weight before slaughter were greater for the animals fed with 20 g/kg DM fennel powder compared to those lambs fed with the control diet (0 vs 20 g/kg DM fennel powder). However, the liver weight was lower in the animals fed with 20 g/kg DM fennel powder compared to those fed with the control diet (3.50 and 4.40 vs. 1.70 ng/dl, P < 0.05). It is noteworthy that concentrations of blood liver enzymes SGOT and SGPT only decreased by adding 10 g/kg DM fennel powder to the diet compared to the control animals (P < 0.05). However, no significant difference was found between the animals fed with 20 g/kg DM fennel powder and the lambs fed with 0 g/kg DM fennel powder (control). The results of two-way ANOVA analysis in terms of the comparison of the means among different tissues and different levels of fennel seed powder feeding for DLK1 expression based on LSD test are shown in Tables 5 and 6.

The comparison of means among different tissues and fennel seed powder consumption (with different levels) for of DLK1 expression based on LSD test is given in Figure 1. When the lambs were fed with the diets with high fennel level, the expression level of DLK1 in the studied tissues (including testis, liver, and humeral muscle) enhanced (P < 0.05). The highest rate of expression for DLK1 was observed in the lambs fed with the diets with 20 g/kg DM fennel powder. For the addition of fennel seed powder to diet at 10 g/kg DM level, the testis, humeral muscle, and liver tissues showed greater DLK1 expression in humeral muscle and liver tissues compared to testis tissues (P < 0.05). Moreover, at 20 g/kg DM level of fennel powder feeding, DLK1 was more expressed in the humeral muscle and liver tissues compared to the testis tissue, which was the most significant effect.

Table 2. Oligonucleotide primers used for RT-PCR analysis of DLK1 (target gene) and ACTB (reference gene) in Kermani lamb tissues.

| Studied genes        | Sequence of used primer (5’-3’) | GenBank No.    | Tm (°C) | Size of amplicon (bp) | Efficiency (%) |
|----------------------|---------------------------------|----------------|---------|----------------------|----------------|
| DLK1 (Target gene)   | F: CGTCTCCTCAACAGTGGCGA R: TCTCCCGGCGTGTGTAGTG | NM-174037      | 57      | 102                  | 98             |
| beta actin (ACTB)    | F: CGTGGAAGACCGGCAAT R: GGGCGGACTGTCATAAC | NM_001101.3    | 57      | 144                  | 99             |
transaminase (U/L) and this increase was due to the addition of fennel. The results of the current study are in line with the results of some other researchers who have shown that fennel could improve FC (Benchraa et al., 2007; Meyer et al., 2007; Soltan, 2009; Vakili et al., 2013). Flavoring herbs have been found to contain chemicals with the property to modulate bacterial fermentation in the rumen and to reduce methane production, thereby improving FC (Evan and Martin, 2000). Zolfaghari Moheb et al. (2015) in their research have used diets containing 9% fennel to feed lambs, and as a result, they have reported that FC improved. Considering that lambs fed with diets containing 20 g/kg DM fennel powder had better performance and this was confirmed by better FC, it can be concluded that the use of medicinal plants to stimulate and improve growth can lead to some positive economic effects on production industry, especially meat production.

Increasing the amount of fennel powder in diets of the studied animals was found to be associated with higher expression of DLK1 in the studied tissues (including testis, liver, and humeral muscle). In another study, Yuan et al. (2018) showed that the expression of DLK1 is upregulated in testis. Additionally, Lottrup et al. (2015) in their study have investigated the potentials of Leydig cells developmental markers and adrenal steroidogenic markers in the differential diagnosis of testicular adrenal rest tumors and malignant Leydig cells tumors. According to their findings, testicular steroidogenic enzymes was expressed in all specimens and DLK1 was highly expressed in testicular adrenal rest tumors. Malignant Leydig cells tumors seem to have lost DLK1 expression and did not resemble immature Leydig cells. In regard to the stimulating effect of fennel powder on the expression of DLK1 in the testis as well as the role of this gene in preventing cancer in testis (Lottrup et al., 2015), it can be concluded that using fennel powder may possibly play a role in the prevention of cancer in the testis tissue, which can be investigated. Although in confirmation of this suggestion, it is necessary to study the role of fennel powder in the expression of DLK1 in both healthy and cancer testis tissues more precisely. The addition of fennel powder to the diets of the studies sheep consequently increased the weight of testis and concentration of testosterone. In this regard, Ghorbani-Ranjbari et al. (2014) have added nettle plant to the diet of rams and reported that blood level of testosterone and weight of testis decreased in response to the phyto-estrogenic characteristics of nettle plant. As well, it has been shown that hydro-alcoholic compounds of chamomile plant can enhance the number of spermatozoa, weight of testis, and concentration of blood testosterone in rat, which can be attributed to the presence of antioxidants. Plants with bioactive compounds have a dose-dependent effect on spermatogenesis. Correspondingly, in the study by Heydari et al. (2008), the production of sperm reduced in the high dose of rosemary, but its low dose had no effect on sperm production. In regards to our results and results of the above-mentioned investigations, it can be concluded that one of the ways to increase testosterone concentration is the use of fennel powder in the diet of lambs.

The improved FC (indicated by a lower value) was observed in the diet containing 20 g/kg DM fennel powder, which may be related to higher daily weight gain of the animals. FC for Iranian meat sheep breeds varies in the range of 5–7. As well, according to the study by Sol-taniNerhad et al. (2016), it is affected by various factors such as age, diet, breed, and weight. In another study, Benchaa et al. (2006) have added herbal flavors up to 2% to the diet of fattening cows and demonstrated that it could improve FC. Moreover, in a study by Saeedi et al. (2017), fennel seed powder (FSP) was added to the dairy cattle starter diets, and it was observed that it improved FC. Therefore, they have concluded that

### Table 4. The effect of feeding fennel powder on blood liver enzymes of serum glutamic oxaloacetic transaminase (SGOT), serum glutamic pyruvic transaminase (SGPT) and testosterone in Kermanshah sheep.

| Assessed variables | Fennel consumption (g/Kg DM) | P value | SEM |
|--------------------|------------------------------|---------|-----|
|                    | 0 | 10 | 20 |         |
| Testosterone (ng/dl) | 1.70a 3.50b 4.40c | 0.025 | 0.23 |

| Serum glutamic oxaloacetic transaminase (U/L) | 112.60a 78.60b 105.20c | 0.001 | 2.85 |

### Table 5. Two-way ANOVA analysis for expression of DLK1 in Kermanshah lambs in different tissues at different levels of fennel feeding.

| Source of variation | df | Mean square |
|---------------------|----|-------------|
| Tissue              | 2  | 1.1233**    |
| Fennel              | 2  | 16.8133**   |
| Tissue × Fennel     | 4  | 0.8733**    |
| Coeff Var           |    | 3.46        |

### Table 6. Comparison of means between different tissues and different levels of fennel feeding for expression of DLK1 in Kermanshah lambs based on LSD test.

| Tissue               | Level of fennel (g/Kg DM) | Mean |
|----------------------|----------------------------|------|
|                      | 0 | 10 | 20 | Mean |
| Humeral muscle       | 1.00a 2.40b 4.80c | 2.73c |
| Liver                | 1.00a 2.60b 3.30b | 2.30b |
| Testis               | 1.00a 2.00b | 3.10b | 2.03c |
| Tissue mean          | 1.00a 2.33b | 3.73a |

Treatments that have at least one letter in common do not differ significantly. Fennel mean column numbers are compared with each other (a, b, and c), tissue mean row numbers are compared with each other (a, b, c, and d), and other numbers that show the interaction between tissue and Level of fennel (g/Kg DM) are compared with each other (a, b, c, d, e, f, and g).

in the liver tissue (P < 0.05). Of note, fennel consumption and tissue interaction effects were also found to be significant.

### 4. Discussion

By investigating the DLK1 expression, it was demonstrated that this gene was expressed in all humeral muscle, liver, and testis tissues of the studied animals. Accordingly, the humeral muscle tissue had the highest DLK1 gene expression in comparison to other studied tissues. These results are consistent with those of various studies that have previously shown the DLK1 expression in muscle of mouse (Yevtodylenko and Schmidt, 2006) and pigs (Oczkowicz et al., 2010), testis of human (Lottrup et al., 2015) and mice (Yuan et al., 2018), and liver of mice (Tanimizu et al., 2003) and pigs (Oczkowicz et al., 2010).

The improved FC (indicated by a lower value) was observed in the diet containing 20 g/kg DM fennel powder, which may be related to higher daily weight gain of the animals. FC for Iranian meat sheep breeds varies in the range of 5–7. As well, according to the study by Sol-taniNerhad et al. (2016), it is affected by various factors such as age, diet, breed, and weight. In another study, Benchaa et al. (2006) have added herbal flavors up to 2% to the diet of fattening cows and demonstrated that it could improve FC. Moreover, in a study by Saeedi et al. (2017), fennel seed powder (FSP) was added to the dairy cattle starter diets, and it was observed that it improved FC. Therefore, they have concluded that...
and SGOT blood liver enzymes. On the other hand, the addition of 20 g/kg DM fennel powder to diet increased the concentration of blood liver enzymes SGOT and SGPT compared to 10 g/kg DM fennel powder. While this concentration decreased in comparison to 0 g/kg DM fennel powder, which may be due to superior quantity of anethole in the diet containing 20 g/kg DM fennel seed powder. Based on the report by Bazmi et al. (2015), several combinations such as transanethole, cumarin, ethyl acetate, and their extractions from hogweed plant enhanced SGOT and SGPT levels. In another study, Eman et al. (2011) have reported that some components of fennel seed such as β-myrcene and D-limonene have an efficient hepatoprotective function. Membrane lipids peroxidation is created by free radicals and this peroxidation consequently enhances enzymes of liver, in order to increase defense system of the body. The increased dry matter intake increases the weight of visceral organs, including the liver. Because the amount of dry matter consumption in the treatment 3 (20 g/kg DM fennel) was slightly higher than the treatment 2 (10 g/kg DM fennel), this slight difference can cause a non-significant difference in liver weights between these two treatments. In addition, the increased dry matter intake in the treatment 3 (20 g/kg DM fennel) probably increased the passage rate in the gastrointestinal tract and then led diet 3 (20 g/kg DM fennel) to play minor role in reducing the liver enzymes SGOT and SGPT, compared to the treatment 2 (10 g/kg DM fennel).

In the present study, an increase was observed in humeral muscle weight and eye muscle area along with an associated increase in the DLK1 expression. The DLK1 expression in the muscle has been previously described in the studies by Su et al. (2014), Yevtodiyenko and Schmidt (2006), Oczkowicz et al. (2010), and Davis et al. (2004). Moreover, the DLK1 expression has been described in the muscle of sheep (Yevtodiyenko and Schmidt 2006), and it was concluded that DLK1 plays a significant role in muscle growth. The considerable, positive association among the expression of IGF1 and DLK1, fiber shear stress, and fiber diameter of muscle has been reported as well (Su et al., 2014). In another study, Davis et al. (2005) have shown that over-expressing DLK1 in the transgenic mice skeletal muscle significantly improves mass and fiber size of muscle, which is known as the cause of muscle hypertrophy in callipyge sheep (Kim et al., 2004). As well, Waddell et al. (2010) have reported that hypertrophy of muscle and distinction of neighbouring satellite cells are enhanced by the DLK1 expression via aborning or regenerating myofibers. Additionally, Davis et al. (2005) have demonstrated that fiber size and mass of muscle are significantly increased by DLK1. In our previous study, it was found that enriching the diet of lambs with fennel seed powder can consequently result in the increased DLK1 expression in the femur muscle because the addition of 20 g/kg DM fennel to the diet significantly increased the expression of DLK1 in this tissue compared to the control group (0 g/kg DM fennel) (Masoudzadeh et al., 2020).

In another study, Yu et al. (2018) have identified genes directly responding to DLK1 signaling in Callipyge sheep and indicated that DLK1 expression was significantly increased in hypertrophied muscles, but not in non-hypertrophied muscles. They have concluded that retrotransposon-like 1 (RTL1) alone is insufficient to induce muscle hypertrophy and DLK1 is the likely primary inducer of the hypertrophy phenotype. Based on our results, DLK1 expression can be increased in different tissues of Kermani lambs by fennel powder consumption, but more studies are needed to take into account various genetic, epigenetic, and physiological statuses to achieve a more decisive result in this regard.

5. Conclusion

In this study, we reported that increasing DLK1 expression is associated with the consumption of fennel powder, along with causing some positive effects on FC, physiological, and growth characteristics. Our results show that using fennel powder in the diets of Kermani lamb can be effective on the expression of DLK1 in three important tissues, including the testis, liver, and muscle. The increased concentrations of testosterone and blood liver enzymes SGOT and SGPT along with the increased humeral muscle weight and area were also reported, which presumably are the affirmative consequences of DLK1 expression. As fennel feeding was found to be associated with the enhanced level of DLK1 expression in several tissues (including testis, liver, and muscle), diet supplementation with this herb should be remarked for improving the growth of animals and mass of muscle, which is of great importance in the farm animal breeding, especially meat production. For obtaining a final and accurate
conclusion on the benefits of using fennel as a feed supplement used to improve sheep production traits, in the future studies, physiological and epigenetic aspects should be considered in addition to genetic aspects. This research highlighted the need for more extensive research in this area.

Declarations

Author contribution statement

Mohammadreza Mohammadabadi: Conceived and designed the experiments; Performed the experiments; Analyzed and interpreted the data; Contributed reagents, materials, analysis tools or data; Wrote the paper.

Seyed Hojat Masouzadeh: Performed the experiments; Analyzed and interpreted the data; Contributed reagents, materials, analysis tools or data.

Amin Khezri; Valentyna Petrivna Oleshko: Conceived and designed the experiments; Wrote the paper.

Oleksandr Kalashnyk; Ruslana Volodymyrivna Stavetska: Performed the experiments; Analyzed and interpreted the data; Wrote the paper.

Nataliia Ihorivna Klopienko: Analyzed and interpreted the data; Wrote the paper.

Serhii Vaslyiovych Tkachenko: Performed the experiments; Analyzed and interpreted the data.

Funding statement

This work was supported by Shahid Bahonar University of Kerman, the Vice Chancellor for Research and Technology (Grant number: G-311/77). The authors declare no conflict of interest.

Additional information

Supplementary content related to this article has been published online at https://doi.org/10.1016/j.helyon.2021.e08542.

Acknowledgements

We would like to thank the animal science department of our university to provide animal breeding units as well as equipment needed in laboratories.
