Non-minimal state-space polynomial form of the Kalman filter for a general noise model

E.D. Wilson, Q. Clairon and C.J. Taylor

The optimal refined instrumental variable method for the estimation of the Box–Jenkins (BJ) model is modified so that it functions as an optimal filter and state-estimation algorithm. In contrast to the previously developed minimal and non-minimal state-space (NMSM) forms for an Auto-Regressive Moving Average with eXogenous variables (ARMAX) model, the new algorithm requires the introduction of a novel extended NMSM form. This facilitates representation of the more general noise component of the BJ model. The approach can be used for adaptive filtering and state variable feedback control.

Introduction: The interesting links between state and parameter estimation have been commented on ever since the publication of Kalman’s seminal work [1–3]. Young [4], for example shows how the state-space Kalman filter representation of a discrete-time system can be converted, in the asymptotic case, into the transfer function form. The refined instrumental variable (RIV) method of recursive parameter estimation is used to estimate the coefficients of this model [5] and hence, following some manipulation, generate the optimal filtered output \( \hat{y}_k \) and states \( \hat{x}_k \). Among several important improvements in recent years, the latest RIV methods (e.g. [6], [2] pp. 200–212, [7] pp 218–226) facilitate the estimation of the following Box–Jenkins (BJ) model, expressed here in single-input \( u_k \), single-output \( y_k \) form for brevity

\[
y_k = \frac{B(z^{-1})}{A(z^{-1})} u_k + \frac{D(z^{-1})}{A(z^{-1})} e_k
\]

where \( e_k = N(0, \sigma^2) \), \( A(z^{-1}) = 1 + a_1 z^{-1} + \cdots + a_N z^{-N} \), \( B(z^{-1}) = b_1 z^{-1} + \cdots + b_M z^{-M} \), \( C(z^{-1}) = 1 + c_1 z^{-1} + \cdots + c_M z^{-M} \) and \( D(z^{-1}) = 1 + d_1 z^{-1} + \cdots + d_M z^{-M} \), in which \( z^{-1} \) is the backward shift operator, i.e. \( z^{-1} y_{k-1} = y_{k-2} \). Although the associated ‘RIVBJ’ algorithm is relatively computationally expensive, for some estimation problems it proves essential (see references above for examples).

However, the minimal canonical state space form utilised to implement the Kalman filter in [4], always yields an Auto-Regressive Moving Average eXogenous variables (ARMAX) model, i.e. similar to (1) but constrained by \( C(z^{-1}) = A(z^{-1}) \). Furthermore, while Taylor et al. [7], and other prior work cited within, use a non-minimal state-space (NMSM) model for generalised digital control, including linear quadratic Gaussian (LQG) design with a Kalman filter, it is similarly limited to the ARMAX model form. Hence, this Letter develops a novel extended stochastic NMSM representation for the more general system in (1). This result completes the link between the latest RIVBJ estimation algorithm and adaptive optimal filtering and can be conveniently exploited for practical control system design.

Background: Consider the following stochastic state-space model:

\[
x_{k+1} = \mathbf{F} x_k + \mathbf{G} u_{k-1} + \mathbf{w}_k, \quad y_k = \mathbf{h} x_k + e_k
\]

where \( \mathbf{w}_k \sim N(0, \mathbf{R}) \) and \( e_k \sim N(\mathbf{0}, \mathbf{q}) \) represent state disturbances and measurement noise respectively, and \( N \) is a positive semi-definite covariance matrix. The Kalman filter representation is

\[
\hat{x}_k = \mathbf{F} \hat{x}_{k-1} + \mathbf{G} u_{k-1} + \mathbf{L}_k e_{k-1}, \quad \hat{y}_k = \mathbf{h} \hat{x}_k + e_k
\]

where \( e_k \) are the innovations, with \( e_k \sim N(\mathbf{0}, \mathbf{q}) \). Introducing \( z^{-1} \) to (3) and assuming \( \mathbf{L}_k \) converges to \( \mathbf{L} \), yields

\[
y_k = q^{-1/2} y_k + \frac{qz^{-1}}{1+qz^{-1}} e_k \quad \text{where} \quad q = h(1 - F z^{-1})
\]

The non-minimal state vector most typically associated with (2) is

\[
x = [y_k \cdots y_{k-N+1}, u_{k-1} \cdots u_{k-M}]’
\]

for which \( [\mathbf{F}, \mathbf{G}] \) are fully defined in many earlier articles [7]. In this case, (4) is equivalent to an ARMAX model [7, 8]. A similar result is stated by Young [4] for a minimal observable canonical form.

Proposition: To express the ‘full’ BJ model (1) in stochastic state-space form, the NMSM state vector is extended as follows:

\[
x = [y_k y_{k-1} \cdots y_{k-N+1} u_{k-1} \cdots u_{k-M+1}]
\]

where \( N = n + p \) and \( M = m + p \). Evaluating \( A(z^{-1}) C(z^{-1}) = 1 + a_1 z^{-1} + \cdots + a_N z^{-N} \) and \( B(z^{-1}) C(z^{-1}) = b_1 z^{-1} + \cdots + b_M z^{-M} \), the state matrices in (2) are

\[
\begin{bmatrix}
-a_1 & -a_2 & \cdots & -a_{N-1} & a_N & b_1 & b_2 & \cdots & b_{M-1} & b_M \\
1 & 0 & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 & 0 \\
0 & 1 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\n0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\n0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
\end{bmatrix}
\]

\[F = \begin{bmatrix} \vdots \end{bmatrix}
\]

\[g = [\beta_1 \ 0 \ \cdots \ 0 \ 0 \ 1 \ 0 \ \cdots \ 0 \ 0 \ 0]
\]

\[h = [1 \ \ 0 \ \ 0 \ \ 0 \ \ 0 \ \ 0 \ \ 0]
\]

The equivalence between the polynomial representation (1) and the state-space model based on (6) is demonstrated in the following.

Demonstration: Defining \( R = N + M - 1 \), and substituting (7) and (9) into \( q \) in (4), yields \( q = [1 \ q_1 \ \cdots \ q_N]’ \), where

\[
q_j = \frac{1}{1 + \sum_{i=1}^{N} a_i z^{-i+j}} \quad \text{if} \ j = 1
\]

\[
q_j = \sum_{i=1}^{N} a_i z^{-i+j} \quad \text{if} \ 2 \leq j \leq N
\]

Resolving the output equation in (4) yields

\[
q z^{-1} + 1 = \frac{1 + f_1 z^{-1} + \cdots + f_N z^{-N}}{1 + \sum_{i=1}^{N} a_i z^{-i}}
\]

\[
f_j = a_j - \sum_{i=1}^{N} f_{i-j} a_i \quad \text{if} \ j = 1
\]

Since past values of the control input are exactly known, the Kalman gain vector associated with (3) is defined \( \mathbf{L} = [l_1 \ l_2 \ \cdots \ l_N \ 0 \ \cdots \ 0\]’. Here, \( l_1 \cdots l_N \) are conventionally determined by specifying \( [\sigma^2, N] \) in some manner and exploiting the matrix Riccati equations [3, 7]. In this Letter, however, the model structure can alternatively be selected by the modeller or identified from data (see below) in order to define the noise transfer function, and the gains follow directly from this. For example, specifying \( F(z^{-1}) = A(z^{-1}) \) yields an auto-regressive noise model type, i.e. \( q z^{-1} + 1 = \frac{1}{1+1/C(z^{-1})} \), while \( F(z^{-1}) = M(z^{-1}) D(z^{-1}) \) yields \( q z^{-1} + 1 = D(z^{-1})/C(z^{-1}) \). In the latter case, (4) is equivalent to the BJ model (1).

Estimated output: Using the innovations \( e_k = y_k - \hat{h}_k \), from (3) and the BJ model (1), the optimal estimate of the output \( \hat{y}_k \) is

\[
\hat{y}_k = D(z^{-1}) C(z^{-1}) y_k + B(z^{-1}) C(z^{-1}) u_k
\]

The RIV algorithm [2] can be used to identify the order and estimate the parameters of the polynomials \( A(z^{-1}) \), \( B(z^{-1}) \), \( C(z^{-1}) \) and \( D(z^{-1}) \) either off-line (in block solution) or adaptively (recursive mode), with \( \hat{y}_k \) subsequently determined using (11) and, for example used for state variable feedback control. Alternatively, in the RIV algorithm, the measured
input \( u_k \) and output \( y_k \) signals are filtered by adaptive prefilers and the outputs of these filters (denoted \( u'_k \) and \( y'_k \)) can be used to estimate \( \hat{y}_k \) directly. The adaptive RIV prefilers used for the BJ model (1) have the form \( C(z^{-1})/(A(z^{-1})D(z^{-1})) \) (see [2, 7] and the references therein), hence \( \hat{y}_k = B(z^{-1})u'_k - A(z^{-1})y'_k + y_k \).

Example: The system model in this example is based on (1) with \( n = m = p = q = 2 \). Using the demonstration above, this system is equivalently described by (6)–(9), with \( L = [1 \ 1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0] \) and

\[
\begin{align*}
l_1 &= d_1 - c_1, & l_2 &= \frac{1}{c_2}(c_1 - d_2) \\
l_3 &= \frac{1}{a_4}(a_3 - l_2a_3 - d_3a_3 - d_3a_1) \\
l_4 &= \frac{1}{a_4}(a_2 - l_2a_2 - l_1a_3 - a_1d_1 - d_2 - d_2 - a_4)
\end{align*}
\]

The optimal estimate of the output can be determined using the polynomial or state-space forms shown in Fig. 1, or within the RIV algorithm by means of the prefilers.

Control design: The extended state-space model (6)–(9) is not fully controllable. This result is transparent from the determinisitic component of (4), i.e. \( y_2 = g_2z^{-1}u_1 \), for which (10) highlights pole-zero cancellations. More formally, the state vector has length \( n + m + p \), while the maximum rank of the associated controllability matrix is \( n + m + p \). However, this observation does not limit the application of state variable feedback control, since a conventional controllable NMSS form, based on (5), can still be utilised for state variable feedback design [7]. Exploiting the separation theorem as usual, the resulting control law is applied to the estimated state, i.e. \( u_k = -k\hat{y}_k \), where \( k \) is the control gain vector. Here, an integral-of-error state, based on the estimated \( \hat{y}_k \) or measured \( y_k \) output, or sometimes an \textit{ad-hoc} hybrid of these [8], is usually included to ensure Type 1 servomechanism performance. Although such extensions are beyond the scope of this Letter, the authors are presently investigating their utility in the context of the new NMSS form.

Conclusions: A novel stochastic NMSS form that enables representation of a general BJ transfer function model was presented. This Letter points out that the approach can be used for both adaptive optimal filtering and state variable feedback control. The new result immediately facilitates representation of a more general noise model for NMSS design than hitherto, and hence facilitates further research into the RIV parameter estimation, LQG optimal control and adaptive filtering in this context. For brevity, this Letter was limited to the single-input, single-output case but multi-input models are also possible.
