**Abstract**

The three-site Pati-Salam gauge model provides a consistent description for the hints of lepton-flavor non-universality observed in $B$ decays, connecting the present pattern of “anomalies” to the origin of the Standard Model Yukawa couplings. We present here a detailed analysis of the model predictions for a series of low-energy observables, mainly in $B$ and $\tau$ physics. The model is in good agreement with present data and predicts a well-defined pattern of non-standard effects in low-energy observables that could allow us to test it in the near future. Particularly interesting are the predictions of large $\tau \to \mu$ Lepton Flavor Violating processes, such as $\tau \to \mu\gamma$, $\tau \to 3\mu$, $B \to K\tau\mu$, and $B_s \to \tau\mu$. Also $\mu \to 3e$, $\mu \to e\gamma$, and $K_L \to \mu e$ decays could be not far from the present exclusion bounds, although this conclusion is more model dependent.

1 Introduction

In a recent paper [1] we have proposed a model based on the flavor non-universal gauge group $PS^3 = [SU(4) \times SU(2)_L \times SU(2)_R]^3$ as an interesting framework to describe the hints of lepton-flavor non-universality observed in $B$ meson decays, both in neutral currents [2, 3] and in charged currents [4–7]. Besides the phenomenological success, the virtue of this model is the natural link between the pattern of "anomalies" observed so far and the hierarchical structure of quark and lepton mass matrices: both structures follow from the same dynamical breaking of the flavor symmetry present in the model. This, together with the unification of quarks and lepton quantum numbers à la Pati-Salam [8], makes the model quite interesting and worth being further investigated. The purpose of this paper is to analyze in more detail the rich low-energy phenomenology of the model, which presents several distinctive features with respect to other models proposed so far for a combined explanation of the two sets of anomalies.

The link between the anomalies and Yukawa couplings in the $PS^3$ model follows from an approximate $U(2)^5$ flavor symmetry [9–11] that, as shown in a series of recent papers, provides a natural starting point to address this problem [12–15]. Interestingly enough, in the $PS^3$ model the $U(2)^5$ flavor symmetry is an accidental symmetry of the gauge sector of the theory (below about 100 TeV) and its breaking is controlled by the spontaneous symmetry breaking $PS^3 \rightarrow SM$. The main TeV-scale mediator responsible for the $B$ anomalies is a vector leptoquark field, $U \sim (3, 1)_{2/3}$, which has already been identified as an excellent single mediator for the anomalies (assuming pure left-handed couplings) in Ref. [13, 15, 16], and has indeed been at the center of a series of explicit model-building attempts [17–22].

The difference of the $PS^3$ model with respect to these previous attempts is twofold: on the one hand, two other TeV-scale fields can mediate flavor-changing processes: a color octet and a $Z'$ (as also in [18]); on the other hand, all these TeV fields are not only coupled to left-handed currents, but also to right-handed currents.

In this paper we present a systematic analysis of the low-energy phenomenology of the model. We focus mainly on the effects of the TeV-scale gauge mediators in processes involving the transition of the $b$ quark and $\tau$ lepton into lighter fermions, since they are the most directly connected to the anomalies. In particular, we show that if the anomalies were to be confirmed, the model would predict a rather characteristic pattern of correlations among these observables. Processes involving only the light families, such as those in $K$ and $D$ physics and $\mu \rightarrow e$ transitions, are controlled by subleading free parameters (more precisely subleading breaking terms of the $U(2)^5$ symmetry) which are constrained neither by the anomalies nor by the Yukawa couplings and are therefore more model dependent. As far as these transitions are concerned, we investigate the consistency of the model and the constraints on these subleading effects arising from neutral meson mixing and $\mu \rightarrow e$ Lepton Flavor Violating (LFV) observables.

The paper is organized as follows: in Section 2 we summarize the key features of the model, focusing in particular on the flavor structure of the massive gauge bosons at the TeV scale. In Section 3 we briefly illustrate the procedure adopted to integrate out the heavy fields and build a corresponding low-energy effective theory. In Section 4 we present a detailed analytical discussion of the most interesting observables, namely $\Delta F = 2$ amplitudes, $b \rightarrow c\ell\nu$ decays, $b \rightarrow s\ell\ell$ decays, and LFV processes. The results of a global fit and a general discussion of the low-energy phenomenology is presented in Section 5. The results are summarized in the

---

1 Interesting recent attempts to explain the anomalies not based on vector leptoquark mediators have been presented in Ref. [23–32].
conclusions. A series of technical details about the model, the construction of the low-energy effective theory, and expressions for the observables are reported in the various appendices.

2 The PS$^3$ model

In this section we briefly summarize the main features of the model, with particular attention to its flavor structure, that plays a key role in low-energy flavor-changing observables, and to the spectrum of exotic gauge bosons at the TeV scale.

2.1 High-scale dynamics

The gauge symmetry holding at high energies is $PS^3 \equiv PS_1 \times PS_2 \times PS_3$, where $PS_i = SU(4)_i \times [SU(2)_L]^i \times [SU(2)_R]^i$. The fermion content is the same as in the SM plus three right-handed neutrinos, such that each fermion family is embedded in left- and right-handed multiplets of a given $PS_i$ subgroup: $(4, 2, 1)_i$ and $(4, 1, 2)_i$. At this level the index $i = 1, 2, 3$ can be identified with the generation index. The SM gauge group is a subgroup of the diagonal group, $PS_{\text{diag}} = PS_{1+2+3}$. The spontaneous symmetry breaking (SSB) $PS^3 \rightarrow \text{SM}$ occurs in a series of steps at different energy scales, with appropriate scalar fields acquiring non-vanishing vacuum expectation values (VEVs), as described in Ref. [1].

As far as low-energy physics is concerned, we can ignore what happens above the scale where the initial gauge group is spontaneously broken to $\text{SM}_{1+2} \times PS_3$. This SSB scale ($\Lambda_{12}$) is chosen sufficiently high to neglect the effect of the $d \geq 6$ effective operators generated at this scale, even for rare processes such as $K_L \rightarrow \mu e$ or $K^- \bar{K}$ mixing. The key aspect of the $SM_{1+2} \times PS_3$ local symmetry is the corresponding accidental $U(2)^5$ global flavor symmetry [9,11]

$$U(2)^5 = U(2)_q \times U(2)_e \times U(2)_u \times U(2)_d \times U(2)_\ell,$$

acting on the first two generations of SM fermions, in the limit where we ignore the scalar sector of the theory.

The SSB $SM_{1+2} \times PS_3 \rightarrow \text{SM}$ occurs below the scale $\Lambda_{23} = \text{few} \times 10 \text{ TeV}$ via an appropriate set of scalar (link) fields acquiring a non-trivial VEV\footnote{For simplicity, we classify the link fields according to their transformation properties under $[SU(2)_R]_{1+2}$, rather than $[U(1)_Y]_{1+2}$. We also changed notation for the link fields with respect to Ref. [1], given we focus only in the last step of the breaking chain.}

$$\Phi_L \sim (1, 2, 1)_{1+2} \times (\bar{4}, 2, 1)_3,$$
$$\Phi_R \sim (1, 1, 2)_{1+2} \times (1, 1, \bar{2})_3,$$
$$\Omega_1 \sim (1, 2, 1)_{1+2} \times (\bar{4}, 2, 1)_3,$$
$$\Omega_3 \sim (3, 2, 1)_{1+2} \times (\bar{4}, 2, 1)_3.$$  

(2.2)

The VEV of such fields obey a hierarchical pattern, $\langle \Phi_L,R \rangle \gg \langle \Omega_{1,3} \rangle$, such that the heavy fields with masses proportional to $\langle \Phi_L,R \rangle = \mathcal{O}(10 \text{ TeV})$ can safely be decoupled due to their heavy mass and the $U(2)^5$ flavor symmetry.

The gauge bosons responsible for the flavor anomalies, and potentially relevant in many flavor observables, are those acquiring mass in the last step of the breaking chain,

$$SU(4)_3 \times SU(3)_{1+2} \times SU(2)_L \times U(1)' \rightarrow \text{SM},$$

(2.3)

triggered by $\langle \Omega_{1,3} \rangle \neq 0$ around the TeV scale. The 15 broken generators give rise to the following massive spin-1 fields: a leptoquark, $U \sim (3, 1)_{2/3}$, a coloron, $G' \sim (8, 1)_0$, and a
\( Z' \sim (1, 1)_0 \). As we discuss below, these are not the only TeV-scale fields: the spectrum contains additional scalars and fermions with masses of the order of a few TeV. However, these play no direct role in low-energy observables.

Finally, the breaking of the electroweak symmetry takes place through the VEV of four SM-like Higgs fields (or two fields transforming as bi-doublets under \( SU(2)_L \times SU(2)_R \)) that, before the breaking of PS, are embedded in the following two scalars:

\[
H_1 \sim (1, 2, \bar{2})_3, \quad H_{15} \sim (15, 2, \bar{2})_3,
\]

with \( \langle H_{15} \rangle \) aligned along the \( T^{15} \) generator of \( SU(4)_3 \). Being singlets of \( SM_{1+2} \), these fields allow us to extend the \( U(2)^5 \) symmetry also to the Yukawa sector, which remains exact at the level of renormalizable operators.

### 2.2 Yukawa couplings and breaking of the \( U(2)^5 \) flavor symmetry

The Yukawa couplings for the light generations and, more generally, the breaking of the \( U(2)^5 \) symmetry, arise from higher-dimensional operators involving the link fields \( \Omega_{1,3} \) and \( \Phi_{L,R} \), generated at the scale \( \Lambda_{23} \). Taking into account the effect of operators up to \( d = 7 \), quark and charged-lepton Yukawa couplings assume the following general parametric structure

\[
Y_f \sim \left( \begin{array}{c}
\frac{\langle \Phi_L \rangle (\Phi_R)}{\Lambda_{23}^2} \\
\frac{\langle \Phi_L \rangle (\Phi_R) \langle \Omega_3 \rangle}{\Lambda_{23}^2} \\
y_3^f
\end{array} \right),
\]

with \( a = 3 \) (1) for quarks (leptons). Here, the 11 (12) entry of this matrix should be understood as a \( 2 \times 2 \) matrix (2-component vector) in flavor space (see appendix \( A \)).

The only entries in Eq. \((2.5)\) induced by renormalizable interactions below the scale \( \Lambda_{23} \) are the Yukawa couplings for the third generation, which arise from

\[
\mathcal{L}_{\text{Yuk}} = y_1 \bar{\Psi}_L^3 H_1 \Psi_R^3 + y_{15} \bar{\Psi}_L^3 H_{15} \Psi_R^3 + y_1' \bar{\Psi}_L^3 H_1 \Psi_R^3 + y_{15}' \bar{\Psi}_L^3 H_{15} \Psi_R^3 + \text{h.c.},
\]

where \( (\Psi_L^3)_{(L(R))} \) denote the PS multiplets of third-generation fermions. Here \( (q_3^R)_{(L(R))} = (t_R, b_R), (\ell_3^R)_{(L(R))} = (\tau_R, \nu^\tau_R) \), and \( q_3^L \) and \( \ell_3^L \) indicate the SM left-handed doublets.

The \( y_3^f \) couplings in Eq. \((2.5)\) are combinations of the \( y_3^{(15)} \) weighted by the VEVs of \( H_1 \) and \( H_{15} \) normalised to \( v = 246 \) GeV. The leading terms controlling the left-handed mixing between third and second generations are generated by the following dimension-five operators

\[
\mathcal{L}_{\Omega}^{d=5} = \frac{y_3^4}{\Lambda_{23}} q^2_L H_1 \Omega_3 \Psi_R^3 + \frac{y_3^6}{\Lambda_{23}} \tilde{q}^2_L H_1 \Omega_1 \Psi_R^3 + \frac{y_3'^4}{\Lambda_{23}} q^2_L H_1' \Omega_3 \Psi_R^3 + \frac{y_3'^6}{\Lambda_{23}} \tilde{q}^2_L H_1' \Omega_1 \Psi_R^3 + \text{h.c.}
\]

The upper index on the left-handed doublets denotes the second family (in the interaction basis) that, by construction, is defined as the fermion combination appearing in these operators (see appendix \( A \)). Similarly, operators of \( d = 6 \) and \( 7 \) involving also the link fields \( \Phi_{L,R} \) are responsible for the subleading terms in \((2.5)\).

The dynamical origin of these higher-dimensional operators is not relevant to analyze low-energy phenomenology. The only important point is the \( U(2)^5 \) symmetry breaking structure

\[^4\text{In the absence of tuning, this Lagrangian predicts } y_1 \text{ and } y_{15} \text{ to be of similar size. As pointed out in } [22], \text{ this prediction can be made compatible with realistic light-neutrino masses by means of an appropriate inverse seesaw mechanism.}\]
they induce. This is highlighted by re-writing each Yukawa matrix in terms of three normalized $U(2)^5$ breaking spurions $\{V_L, V_R, X_{LR}\}$, with hierarchical ordered coefficients ($|\epsilon^f_R| \ll |\epsilon^f_L| \ll |\epsilon^f| \ll 1$):

$$Y_f = y^f_3 \begin{pmatrix} \epsilon^f_{LR} X_{LR} & \epsilon^f_L V_L \\ \epsilon^f_R V^T_R & 1 \end{pmatrix}.$$  

Here $V_L$ and $V_R$ are unit vectors in the $U(2)^{q+\ell}$ and $U(2)^{u+d+e}$ space, while $X_{LR}$ is a bifundamental spurion of $U(2)^5$. As discussed in detail in appendix A, the known structure of the SM Yukawa couplings determines only some of the (complex) coefficients $\epsilon^f_L$. The ones playing a prominent role in the phenomenological analysis are those appearing in the left-handed mixing, generated by the leading spurions. By eliminating parameters that can be expressed in terms of CKM matrix elements, we are left with two key mixing terms ($s_\tau$ and $s_\tau$), and a series of CP-violating phases out of which only two play a relevant role ($\phi_b$ and $\alpha_d$). The left-handed mixing parameters, which are nothing but the magnitudes of the $\epsilon^f_L$ parameters in the down and charged-lepton sector, are expected to be small, the natural size being set by $|V_{ts}|$. The subleading right-handed rotations in the lepton sector, controlled by the parameter $\epsilon^f_R$, play an important role in the rare $B_s \to \ell\ell$ decays and in LFV processes.

An additional important aspect to analyze low-energy physics is the fact that the $U(2)^5$ breaking is not confined only to the Yukawa sector, but it appears also in other effective operators. Among them, those with phenomenological implications at low energies are the $d = 6$ operators bilinear in the light fermion fields and in the $\Omega_{1,3}$ link fields:

$$\mathcal{L}_{\Omega}^{d=6} = \frac{c_{q\ell}}{\Lambda_{23}^2} (X_{q\ell})_{ij} \text{Tr}[i\Omega_2^j D^\mu \Omega_3^i][q^i_L \gamma^\mu q^j_L] + \frac{c_{qq}}{\Lambda_{23}^2} (X_{qq})_{ij} \text{Tr}[i\Omega_2^j D^\mu \Omega_3^i][q^i_q \gamma^\mu q^j_q] + \frac{c_{q\ell}}{\Lambda_{23}^2} (X_{q\ell})_{ij} \text{Tr}[i\Omega_2^j D^\mu \Omega_3^i][\ell^i_L \gamma^\mu \ell^j_L] + \text{h.c.},$$  

(with $i, j = 1, 2$). These operators introduce three new bi-fundamental spurions of $U(2)^5$, $X_{q\ell} \sim 2_q \times \bar{2}_\ell$, $X_{q\ell} \sim 2_\ell \times \bar{2}_q$, and $X_{qq} \sim 2_q \times \bar{2}_q$ that, as shown below, modify the couplings of the TeV-scale vectors to the SM fermions. In order to simplify the phenomenological discussion, it is convenient to define a minimal breaking structure for these additional spurions:

$$X_{q\ell}|_{\min} = 1, \quad X_{\ell\ell}|_{\min} = X_{q\ell}|_{\min} = \text{diag}(0, 1).$$  

(2.10)

This structure corresponds to $U(2)^5$ symmetric couplings for quark currents, and breaking terms aligned to those appearing in the Yukawa couplings for lepton currents. As we show in Section B this minimal breaking structure helps evading the tight bounds from neutral meson mixing while maximizing the impact on the $b \to s\ell\ell$ anomalies. Deviations from this minimal structure are possible, and are unavoidably generated when considering the product of two or more spurions, but cannot be too large (see appendix B). In the limit where we neglect deviations from this structure, the only relevant flavor parameter of the model is

$$\epsilon_U = \frac{c_{q\ell} \omega_1 \omega_3}{2 \Lambda_{23}^2}$$  

(2.11)

(with $\omega_1, 3$ defined in (2.12)), that controls the breaking of $U(2)^5$ in the coupling of the TeV-scale leptoquark field.

For the sake of completeness we present in appendix B an explicit dynamical realization of $\mathcal{L}_{\Omega}^{d=5}$ and $\mathcal{L}_{\Omega}^{d=6}$ in terms of heavy fields to be integrated out. In particular, we show how
these operators and the minimal breaking structure can be generated by integrating out an appropriate set of TeV-scale vector-like fermions with renormalizable interactions at the scale of unbroken SM$_{1+2} \times$ PS$_3$. A discussion about the possible deviations from the minimal breaking structure in Eq. (2.10) is also presented.

In principle, also $d = 6$ operators involving right-handed light fermion fields could be relevant at low-energies. However, it is easy to conceive ultraviolet completions where such operators are not generated (or are extremely suppressed), as in the example presented in the appendix B. As discussed in Ref. [1], all other $d = 6$ operators either contribute to the Yukawa couplings or have negligible impact at low energies.

2.3 The model at the TeV scale

Here we focus on the last step of the breaking chain before reaching the SM, namely Eq. (2.3). With an obvious notation, we denote the gauge couplings before the symmetry breaking by $g_i$, with $i = 1 \ldots 4$, and the gauge fields of SU(4)$_3$, SU(3)$_{1+2}$, and U(1)$'$ by $H_\mu^a$, $A_\mu^a$, and $B_\mu'$, respectively. The symmetry breaking in Eq. (2.3) occurs via the VEVs of $\Omega_{1,3}$ along the SM direction, that we normalize as

$$\langle \Omega_3^\dagger \rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} \omega_3 & 0 & 0 \\ 0 & \omega_3 & 0 \\ 0 & 0 & \omega_3 \end{pmatrix}, \quad \langle \Omega_1^\dagger \rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix},$$  \hspace{1cm} (2.12)

with $\omega_{1,3} = \mathcal{O}(\text{TeV})$. These scalar fields can be decomposed under the unbroken SM subgroup as $\Omega_3 \sim (8, 1)_0 \oplus (1, 1)_0 \oplus (3, 3)_{2/3}$ and $\Omega_1 \sim (3, 1)_{-2/3} \oplus (1, 1)_0$. As a result, after removing the Goldstones, we end up with a real color octect, one real and one complex singlet, and a complex leptoquark.

The gauge spectrum, which coincides with the one originally proposed in Ref. [18], contains the following massive fields

$$U_\mu^{1,2,3} = \frac{1}{\sqrt{2}} \left( H_\mu^{9,11,13} - i H_\mu^{10,12,14} \right), \quad G_\mu^a = \frac{1}{\sqrt{g_3^2 + g_4^2}} (g_3 A_\mu^a - g_4 H_\mu^a),$$

$$Z_\mu' = \frac{1}{\sqrt{g_4^2 + \frac{2}{3} g_1^2}} \left( g_4 H_\mu^{15} - \sqrt{\frac{2}{3}} g_1 B_\mu' \right),$$  \hspace{1cm} (2.13)

with masses

$$M_U = \frac{g_4}{2} \sqrt{\omega_1^2 + \omega_3^2}, \quad M_{G'} = \sqrt{\frac{g_1^2 + g_3^2}{2}} \omega_3, \quad M_{Z'} = \frac{1}{2} \sqrt{\frac{3}{2} g_4^2 + g_1^2} \sqrt{\omega_1^2 + \omega_3^2 / 3}. \hspace{1cm} (2.14)$$

The combinations orthogonal to $G_\mu^a$ and $Z_\mu'$ are the SM gauge fields $G_\mu^a$ and $B_\mu'$, whose couplings are $g_c = g_3 g_4 / (g_3^2 + g_4^2)$ and $g_Y = g_1 g_4 / \sqrt{2} g_4^2 + \frac{2}{3} g_1^2$. For later convenience, we introduce the effective couplings

$$g_U \equiv g_4, \quad g_{G'} \equiv \sqrt{g_3^2 - g_4^2}, \quad g_{Z'} \equiv \frac{1}{2 \sqrt{6}} \sqrt{g_3^2 - \frac{2}{3} g_4^2},$$  \hspace{1cm} (2.15)

that control the strength of the interactions with third-generation fermions. Note that in the limit $g_4 \gg g_3$ (hence $g_U \gg g_c$), one has $g_U \approx g_{G'} \approx 2 \sqrt{6} g_{Z'}$. 

7
The interactions of the heavy gauge bosons with SM fermions (and right-handed neutrinos) are described by the following Lagrangian

\[
\mathcal{L}_{\text{int}} \supset \frac{g_U}{\sqrt{2}} (U_\mu J^\mu_U + \text{h.c.}) - g_{G'} C^a_{\mu} J^\mu_{G'} - g_{Z'} Z^\mu_{\ell} J^\mu_{Z'},
\]

(2.16)

where

\[
J^\mu_U \equiv \bar{q}_L N^L_U \gamma^\mu \ell_L + \bar{u}_R N^R_U \gamma^\mu \nu_R + \bar{d}_R N^R_U \gamma^\mu e_R,
\]

\[
J^\mu_{G'} \equiv \bar{q}_L N^L_{G'} \gamma^\mu q_L + \bar{u}_R N^R_{G'} \gamma^\mu u_R + \bar{d}_R N^R_{G'} \gamma^\mu d_R,
\]

\[
J^\mu_{Z'} \equiv 3 \bar{\ell}_L N^\ell_{Z'} \gamma^\mu \ell_L + 3 \bar{\nu}_R N^\nu_{Z'} \gamma^\mu \nu_R - \bar{\ell}_L N^\ell_{Z'} \gamma^\mu q_L + 3 \bar{\nu}_R N^\nu_{Z'} \gamma^\mu u_R - \bar{\ell}_L N^\ell_{Z'} \gamma^\mu d_R,
\]

and the \(N\)’s are \(3 \times 3\) matrices in flavor space. In the absence of \(U(2)^5\) breaking, these matrices assume the following form in the interaction basis

\[
N^L_{U,R} = N_U \equiv \text{diag} \left(0, 0, 1\right),
\]

\[
N^L_{Z'} = N^d_{Z'} = N_{Z'} \equiv \text{diag} \left(-\frac{2}{3} \left(\frac{g_1}{g_4}\right)^2, 1\right),
\]

\[
N^L_{G',R} = N_{G'} \equiv \text{diag} \left(-\frac{g_3}{g_4}, 1\right),
\]

\[
N^{\ell(q)}_{Z'} = N_{Z'} \pm \frac{2}{3} \left(\frac{g_1}{g_4}\right)^2 \mathbb{1}, \quad N^{u(d)}_{Z'} = N_{Z'} \mp \frac{2}{3} \left(\frac{g_1}{g_4}\right)^2 \mathbb{1}.
\]

(2.17)

The inclusion of the effective operators of \(\mathcal{L}_{\Omega}^{d=6}\) in Eq. [2.9] modifies these flavor couplings into

\[
N^L_U \rightarrow \left(\begin{array}{cc}
\epsilon_U X_{\ell q} & 0 \\
0 & 1
\end{array}\right), \quad N^L_{Z'} \rightarrow N_{Z'}, \quad N^L_{G'} \rightarrow N_{G'},
\]

\[
N^{\ell(q)}_{Z'}(N^{u(d)}_{Z'}) \rightarrow N_{Z'}(N_{G'}), \quad \left(\begin{array}{cc}
\epsilon_{\ell q} X_{\ell q} & 0 \\
0 & 1
\end{array}\right).
\]

(2.18)

As discussed in appendix [2], the natural size for the \(\epsilon_{\ell q,U}\) parameters is \(10^{-3} \lesssim |\epsilon_{\ell q,U}| \lesssim 10^{-2}\). In the limit where we adopt the minimal breaking structure in Eq. [2.10], the \(Z'\) and \(G'\) couplings to quarks remain \(U(2)_q\) symmetric.

When discussing low-energy observables, the heavy vectors are integrated out and the overall strength of their interactions is controlled by three effective Fermi-like couplings

\[
C_U \equiv \frac{g_U^2 v^2}{4 M_U^2}, \quad C_{G'} \equiv \frac{g_{G'}^2 v^2}{4 M_{G'}^2}, \quad C_{Z'} \equiv \frac{g_{Z'}^2 v^2}{4 M_{Z'}^2},
\]

(2.19)

which span a limited range depending on the values of \(\omega_1\) and \(\omega_3\) and, to a smaller extent, \(g_U\). These effective couplings (or better \(\omega_1\) and \(\omega_3\), together with the main flavor parameters discussed above \((s_b, \ s_t, \ \epsilon_U, \ \epsilon_{\ell q})\), the two phases \(\phi_0\) and \(\alpha_3\), and \(\epsilon_R\) controlling right-handed rotations in the lepton sector) are the main free parameters used in the phenomenological analysis of the low-energy observables.
3 Construction of the low-energy EFT

The construction of the EFT relevant for low-energy phenomenology occurs in three steps: i) we integrate out the TeV fields at the tree-level, matching the theory into the so-called SM effective field theory (SMEFT), for which we adopt the Warsaw operator basis [33]; ii) the SMEFT operators are evolved down to the electroweak scale using the one-loop Renormalization Group (RG) equations in Ref. [34–36]. At this point, all the ingredients necessary to check possible modifications of the on-shell $W$ and $Z$ couplings are available. For all the other observables a third step is needed: iii) the heavy SM fields are integrated out and the theory is matched into a low-energy effective field theory (LEFT) containing only light SM fields [37]. The key points of these three steps are briefly illustrated below.

3.1 Matching heavy gauge boson contributions to the SMEFT

Moving from the interaction basis to the quark down-basis, defined in (A.7), and the mass-eigenstate basis of charged leptons, the currents in Eq. (2.17) assume the form

\[ J^\mu_\ell = \bar{q}_L \gamma^\mu \ell_L + \bar{d}_L \gamma^\mu \nu_R + \bar{u}_L \gamma^\mu \nu_R, \]

\[ J^{\alpha \mu}_L = \bar{q}_L \kappa_\alpha \gamma^\mu T^\alpha q_L + \bar{u}_L \kappa_\alpha \gamma^\mu T^\alpha u_L + \bar{d}_L \kappa_\alpha \gamma^\mu T^\alpha d_L, \]

\[ J^\mu_{Z'} = \bar{q}_L \xi_\mu \ell_L - \bar{q}_L \xi_\mu q_L + 3 \bar{u}_R \xi_\mu \nu_R + 3 \bar{d}_R \xi_\mu \nu_R. \]

(3.1)

where the new flavor structures are expressed in terms of the $N$'s and the unitary rotation matrices that diagonalize the Yukawa couplings:

\[ \beta_q = L^d N^\ell L_\ell, \quad \kappa_q = L^d N^\ell L_d, \quad \xi_q = L^d N^\ell L, \quad \xi_\ell = L^e N^\ell L_e, \]

\[ \beta_u = R^u N^R R_\nu, \quad \kappa_u = R^u N^R R_u, \quad \xi_u = R^u N^R R, \quad \xi_\nu = R^e N^R R_e, \]

\[ \beta_d = -R^d N^R R_\nu, \quad \kappa_d = R^d N^R R_d, \quad \xi_d = R^d N^R R_d, \quad \xi_\mu = R^e N^R R_e. \]

(3.2)

The relative sign in $\beta_d$, which plays a key role in the explanation of the $R_{D(s)}$ anomalies, follows from the phase choice discussed in appendix A. Note that, in the case of the $Z'$ current, we have included also the contribution of the SM Higgs ($\phi$), which is obtained combining the four SM-like Higgses of the model.

By integrating out $U$, $Z'$ and $G'$ at the tree level we obtain the effective Lagrangians

\[ \mathcal{L}_{\text{EFT}}^U = -\frac{4G_F}{\sqrt{2}} C_U J^\mu_U J^\dagger_U = -\frac{2}{\Lambda^2} C_U \sum_k B_k Q_k, \]

\[ \mathcal{L}_{\text{EFT}}^G = -\frac{4G_F}{\sqrt{2}} C_G (J^\mu_G) = -\frac{2}{\Lambda^2} C_G \sum_k K_k Q_k, \]

\[ \mathcal{L}_{\text{EFT}}^{Z'} = -\frac{4G_F}{\sqrt{2}} C_{Z'} (J^\mu_{Z'}) = -\frac{2}{\Lambda^2} C_{Z'} \sum_k \Xi_k Q_k, \]

(3.3)

where $Q_k$ denote the SMEFT operators in the Warsaw basis [33], plus additional dimension six operators involving right-handed neutrinos, reported in Table C.1. More compactly,

\[ \mathcal{L}_{\text{SMEFT}} = -\frac{4G_F}{\sqrt{2}} \sum_k C_k Q_k \quad C_k = C_U B_k + C_G K_k + C_{Z'} \Xi_k. \]

(3.4)
Tables C.2, C.3, and C.4 contain the tree level matching results for the SMEFT Wilson coefficients $C_k$.

### 3.2 From the SMEFT to the LEFT

After matching, we perform the RG evolution of the resulting Wilson coefficients using DsixTools [38]. RG effects are particularly important for the scalar operators and for dimension-six operators in the $\bar{\psi}^2 \phi^2 D$ category. The latter introduce modifications to the $W$ and $Z$ after SSB (see e.g. [37]) which are tightly constrained by electroweak precision data at LEP as well as by universality tests in lepton decays [39–41]. NP effects below the electroweak scale are conveniently described in terms of a low-energy effective field theory (LEFT) in which the $W$, the $Z$, the $t$ and the Higgs have been integrated out:

$$L_{\text{LEFT}} = -\frac{4G_F}{\sqrt{2}} \sum_k C_k O_k. \quad (3.5)$$

We then proceed by matching the SMEFT to the LEFT and provide the expressions for the relevant observables in terms of its Wilson coefficients. We adopt the same operator basis for the LEFT as in Table 7 of Ref. [37].

### 4 The key low-energy observables

In what follows we provide simplified expressions for the most relevant low-energy observables, and discuss their role in constraining the model and in offering future test of this framework. This simplified expressions are mainly for illustration purposes; for all figures and numerical estimates throughout the paper we use the full expressions quoted in appendix D.

#### 4.1 $\Delta F = 2$ transitions

As in any extension of the SM with non-trivial flavor structure, also in the PS$^3$ framework $\Delta F = 2$ amplitudes provide one of the most significant constraints on model parameters, particularly on the new sources of flavor violation in the quark sector. These amplitudes receive tree-level contributions mediated by the $Z'$ and $G'$, whose strength is controlled by the $U(2)^5$ breaking spurions. To a good approximation, the three down-type $\Delta F = 2$ amplitudes can be written as

$$M(K^0 \rightarrow \bar{K}^0) \approx |M_{\text{SM}}^d|(V_{td}V_{ts}^*)^2 \left[ e^{-2i\alpha_d} \frac{c_d^4 [s_b^2 + 2 s_b \text{Re}(\bar{\epsilon}_q e^{-i\phi_b}) + \Delta \epsilon_q]^2}{|V_{ts}|^4} F_0 \right] + M_{\text{SM}}^{(tc+cc)},$$

$$M(B_d \rightarrow \bar{B}_d) \approx |M_{\text{SM}}^d|(V_{td}V_{tb}^*)^2 \left[ 1 + \frac{c_d^2 (s_b e^{-i\phi_b} + \bar{\epsilon}_q)^2}{|V_{ts}|^4} F_0 e^{-2i\Delta \alpha_d} \right],$$

$$M(B_s \rightarrow \bar{B}_s) \approx |M_{\text{SM}}^d|(V_{ts}V_{tb}^*)^2 \left[ 1 + \frac{c_d^2 (s_b e^{-i\phi_b} + \bar{\epsilon}_q)^2}{|V_{ts}|^4} F_0 (1 + f(\theta_{bs}^R)) \right], \quad (4.1)$$

4 Contributions to other dimension-six operators that could potentially induce $W$ and $Z$ coupling modifications, such as those of the class $X^2 H^2$ or $Q_{HD}$, are negligible in our model.
Figure 4.1: NP effects in $B_{s,d} - \bar{B}_{s,d}$ mixing as function of the phase $\phi_b$ for $\Delta \alpha_d = 0, \pi$ (left) and $\alpha_d = 0, \pi$ (right). The blue and orange bands correspond to the 95\% CL experimental bounds for $B_s$ and $B_d$ mixing, respectively. We use the following inputs: $s_b = 0.10 |V_{ts}|$ (solid), $s_b = 0.15 |V_{ts}|$ (dashed), $\epsilon^d_R = 0$, $g_\lambda = 3.0$, $M_{Z'} = 1.75$ TeV, and $M_{G'} = 2.5$ TeV.
where

\[ F_0 = \frac{16\pi^2}{\sqrt{2} G_F M_W^2} S_0(x_t) \left( C_{Z'} + \frac{C_{G'}}{3} \right), \]

and \( S_0(x_t = m_t^2/M_W^2) \approx 2.4 \) denotes the SM one-loop function (in the \( \Delta S = 2 \) case we normalize the NP amplitude to the short-distance top-quark SM contribution).

As far as left-handed flavor-mixing parameters are concerned, \( s_b \) and \( \phi_b \) arise from the leading \( U(2)_q \) breaking term in the quark sector; \( \Delta \alpha_d = \alpha_d - (\pi - \text{Arg} \{ V_{td}/V_{ts} \}) \) denotes the phase difference between the leading quark spurion and subleading terms describing light-quark breaking terms in the \( Z' \) and \( G' \) couplings (see appendix [A]).

Finally, \( f(\theta_{bs}^R) \) describes the contributions from the right-handed flavor rotations in (A.18). Using the inputs in [42] for the bag parameters of non-SM operators, we find

\[ f(\theta_{bs}^R) \approx \frac{16 C_{Z'} + 22 C_{G'}}{3 C_{Z'} + C_{G'}} \frac{(\theta_{bs}^R)^*}{C_d s_b e^{-i\phi_b}} + O[(\theta_{bs}^R)^2]. \]  

As shown in appendix [A] in the limit where we neglect contributions to the Yukawa couplings from \( d = 7 \) effective operators, the right-handed rotation angle is unambiguously fixed to \( \theta_{bs}^R = m_s/m_b s_b e^{i\phi_b} \), that in turn implies \( f(\theta_{bs}^R) \approx 0.4 \) for typical values of \( C_{Z'}/C_{G'} \).

**CP violation in Kaon mixing.** The most significant constraints on the subleading parameters \( \Delta \epsilon_q \) and \( \bar{\epsilon}_q \), which describe the deviations from the exact \( U(2)_q \) limit in the \( Z' \) and \( G' \) left-handed couplings, arise from the CP-violating observable \( \epsilon_K \propto \text{Im} \{ \mathcal{M}(K^0 \rightarrow \bar{K}^0) \} \), that can be decomposed as

\[ \epsilon_K \approx \epsilon_{K}^{\text{SM},(tt)} - \sqrt{2} \epsilon_{K}^{\text{SM},(tt)} \sin(2\alpha_d) \left[ s_b^2 + 2 s_b \text{Re}(\bar{\epsilon}_q e^{-i\phi_b}) + \Delta \epsilon_q \right]^2 \frac{c_d^4 F_0}{|V_{ts}|^2}. \]

where \( \epsilon_{K}^{\text{SM},(tt)} \) corresponds to the top-mediated SM contribution. The NP contribution to \( \epsilon_K \) vanishes for \( \alpha_d \rightarrow 0 \). Setting \( \Delta \epsilon_q = \bar{\epsilon}_q = 0 \), and choosing the other parameters in their natural range, we find that \( \epsilon_K \) is well within its current bound, irrespective of the value of \( \alpha_d \). Allowing for \( \Delta \epsilon_q, \bar{\epsilon}_q \neq 0 \), imposing modifications in |\( \epsilon_K \) of up to \( O(15\%) \), and barring accidental cancellations with generic values of \( \alpha_d \), we find

\[ |\Delta \epsilon_q| \lesssim 0.1 |V_{ts}|^2, \quad |\bar{\epsilon}_q| \lesssim 0.3 |V_{ts}|. \]

Similar limits, although slightly less stringent, are obtained from \( B_{s,d} - \bar{B}_{s,d} \) and \( D - \bar{D} \) mixing. Despite being stringent, these limits are below the natural size of these subleading breaking terms inferred in appendix [B] (setting |\( \epsilon_U | \leq 10^{-2} \)). This result implies that: i) it is perfectly consistent to focus on the scenario \( \Delta \epsilon_q = \bar{\epsilon}_q = 0 \); ii) once the symmetry breaking terms assume their natural size, no fine-tuning on the CP-violating phases is necessary in order to satisfy the \( \epsilon_K \) constraint.

**\( \Delta B = 2 \) observables.** Setting \( \Delta \epsilon_q = \bar{\epsilon}_q = 0 \), the physical observables sensitive to \( \Delta B = 2 \) amplitudes, namely the mass differences \( (\Delta M_q) \) and the CP violating asymmetries \( S_{\psi K_S} \) and
$S_{\psi\phi}$ can be expressed as

$$C_{B_d} \equiv \frac{\Delta M_d}{\Delta M_d^{\text{SM}}} \approx 1 + \frac{c_d^2 s_b^2 e^{-2i(\phi_b + \Delta \alpha_d)}}{|V_{ts}|^2} F_0,$$

$$C_{B_s} \equiv \frac{\Delta M_s}{\Delta M_s^{\text{SM}}} \approx 1 + \frac{c_d^2 s_b^2 e^{-2i\phi_b}}{|V_{ts}|^2} F_0 \left(1 + f(\theta^R_{bs})\right),$$  \hspace{1cm} (4.6)

and

$$S_{\psi K_s} = \sin (2\beta + \Phi_{B_d}), \quad \Phi_{B_d} \approx \text{Arg} \left(1 + \frac{c_d^2 s_b^2 e^{-2i(\phi_b + \Delta \alpha_d)}}{|V_{ts}|^2} F_0\right),$$

$$S_{\psi\phi} = \sin (2|\beta_s| - \Phi_{B_s}), \quad \Phi_{B_s} \approx \text{Arg} \left(1 + \frac{c_d^2 s_b^2 e^{-2i\phi_b}}{|V_{ts}|^2} F_0 \left(1 + f(\theta^R_{bs})\right)\right).$$  \hspace{1cm} (4.7)

Current lattice data \cite{42} point to a deficit in the experimental values of $\Delta M_{d,s}$ with respect to the SM prediction (or equivalently to values of $C_{B_{d,s}}$ smaller than one). As show in Figure 4.1, the presence of the free phase $\phi_b$ allows the model to accommodate this deficit, even for small departures from $\phi_b = \pi/2$, while satisfying the bounds from CP violation (see Ref. \cite{43} for a similar discussion). The mixing angle $s_b$ is constrained to be up to 0.2 $|V_{ts}|$ (depending on $\phi_b$), indicating a mild alignment of the leading U(2)$_q$ breaking spurion in the down sector. As we discuss in Section 4.4 in our framework the vector leptoquark provides a good fit of the semileptonic anomalies irrespective of the value of $\phi_b$ (contrary to the case discussed in Ref. \cite{43}). We thus conclude that the model leads to a good description of $\Delta B = 2$ observables, possibly improved compared to the SM case.

**CP violation in $D$ mixing.** Last but not least, we analyze the bounds from $\Delta C = 2$ amplitudes. Following the analysis from UTfit \cite{44,46}, the constraint obtained from the non-observation of CP-violation in the $D - \bar{D}$ transition can be expressed as

$$\text{Im}(C_1^D) = \frac{4G_F}{\sqrt{2}} \text{Im} \left(\left[C_{uu}^{\text{V,LL}}\right]_{2121} (\mu_t)\right) = (-0.03 \pm 0.46) \times 10^{-14} \text{ GeV}^{-2}. \hspace{1cm} (4.8)$$

Taking into account also the subleading breaking terms, we find the following simplified expression for this Wilson coefficient:

$$\text{Im} \left(\frac{C_1^D}{\sqrt{2}}\right) \approx \frac{4G_F}{\sqrt{2}} \text{Im} \left\{(V_{ub}^* V_{cb})^2 \left[1 + c_d (s_b e^{-i\phi_b} + \bar{\epsilon}_q) \frac{V_{tb}}{|V_{ts}|} \Lambda_u \right] \left(1 + c_d (s_b e^{i\phi_b} + \bar{\epsilon}_q) \frac{V_{tb}^*}{|V_{ts}|} \Lambda_c \right) + \Delta \epsilon_q c_d^2 \frac{|V_{tb}|^2}{|V_{ts}|^2} \Lambda_u \Lambda_c^2 \right\} \left(C_{Z'} + \frac{C_{G'}}{3}\right)$$

$$= \frac{4G_F}{\sqrt{2}} \left(C_{Z'} + \frac{C_{G'}}{3}\right) \text{Im} \left\{(V_{ub}^* V_{cb})^2 [1 + \mathcal{O}(s_b, \bar{\epsilon}_q, \Delta \epsilon_q)]\right\}, \hspace{1cm} (4.9)$$

where we have defined

$$\Lambda_i = \frac{V_{ts}|V_{ts}| - V_{td}|V_{td}| e^{i\alpha_d}}{V_{tb}^* V_{tb}} = \begin{cases} 
1 + \mathcal{O}(\lambda^2) \\
1 - \frac{V_{td} V_{td}^*}{V_{ts} V_{os}^*} \left[1 - e^{i\Delta \alpha_s}\right] + \mathcal{O}(\lambda^2) \end{cases} \quad (i = c)$$

$$\Lambda_i = \begin{cases} 
1 + \mathcal{O}(\lambda^2) \\
1 - \frac{V_{td} V_{td}^*}{V_{ts} V_{os}^*} \left[1 - e^{i\Delta \alpha_s}\right] + \mathcal{O}(\lambda^2) \end{cases} \quad (i = u), \hspace{1cm} (4.10)$$

which in the limit $\Delta \alpha_d \to 0$ reduces to the U(2) symmetric result $\Lambda_c = \Lambda_u = 1$. Contrary to down-type observables, in this case non-vanishing NP contributions are generated also in the $s_b \to 0$ limit.
Figure 4.2: Model contributions to $\text{Im}(C^D_1)$ as function of $\phi_b$. We use the following inputs: $s_b = 0.10|V_{ts}|$, $g_4 = 3.0$, $M_{Z'} = 1.75$ TeV, and $M_{G'} = 2.5$ TeV. The dark- and light-blue bands correspond to the 68% and 95% CL bound from UTfit [46], respectively.

Setting to zero the subleading breaking terms ($\Delta \epsilon_q = \tilde{\epsilon}_q = 0$), we find that the experimental bound is satisfied over a wide range of $\{s_b, \phi_b\}$ values compatible with the $\Delta B = 2$ constraints. Note in particular that in the limit where $\Delta \alpha_d = \pi$, we have $\Lambda_u = 1.1 - 4.6i$. In this case the large imaginary piece of $\Lambda_u$, together with the values of $s_b$ and $\phi_b$ introduced to explain the deficit in $\Delta B = 2$ transitions, yields a partial cancellation in $C^D_1$, both in the real and in the imaginary part. This is shown in Figure 4.2 where we plot the $Z'$ and $G'$ mediated tree-level contributions to the imaginary part of $C^D_1$ together with the current bound from UTfit. A similar behaviour is also obtained when $\alpha_d = \pi$, in which case $\Lambda_u = 0.2 - 4.4i$.

### 4.2 LFU tests in charged lepton decays

Beside $\Delta F = 2$ observables, another very relevant set of constraints on the model is posed by LFU tests in charged-lepton decays. These provide an important bound on the overall strength of leptoquark interactions, yielding an upper limit on the possible NP contribution to $R_{D(\tau)}$. Such tests are constructed by performing ratios of the partial widths of a lepton decaying to lighter leptons or hadrons (see appendix D.2). In our model, both the $\mu$ vs $e$ and the $\tau$ vs $\mu$ ratios are modified: the former is dominated by the tree-level exchange of a $Z'$, the latter by a leptoquark loop. Setting $\mu_U = 2$ TeV to evaluate the leptoquark loop we find\footnote{In the $\tau$ vs $\mu$ ratio we include the full RG running from $M_U$ to $m_t$ using DsixTools [38]. Because of the large running effects in the top Yukawa coupling, we find differences of $\mathcal{O}(20\%)$ in the NP contribution when comparing the full RG result to the non-RG improved one-loop expression. We also include the non-logarithmic terms computed in [1].}

\[
\left( \frac{g_\mu}{g_e} \right)_\ell \approx 1 + 9 C_{Z'} s^2_\tau, \quad (4.11)
\]

\[
\left( \frac{g_\tau}{g_\mu} \right)_{\ell, \pi, K} \approx 1 - 0.063 C_U. \quad (4.12)
\]
The high-precision measurements of these effective couplings only allow for per mille modifications of the ratios. This in turn implies a strong bound on the possible value of $C_U$. Taking the HFLAV average in the $\tau$ vs $\mu$ ratio \cite{47} \[
\left( \frac{g_\tau}{g_\mu} \right)_{\ell+\pi+K} = 1.0000 \pm 0.0014. \tag{4.13}\]
we find the following limit on $C_U$ at 95% CL:
\[C_U \lesssim 0.04 \overset{M_U=2\text{ TeV}}{\Longrightarrow} g_4 \lesssim 3.2. \tag{4.14}\]
This bound is shown in Figure \ref{fig:4.3} together with the NP enhancement in $b \to c(\ell)\ell\nu$ transitions. On the other hand, we find that possible modifications in the $\mu$ vs $e$ ratio are of $O(10^{-4})$ and thus do not yield any relevant constraint. We also find that tests of LFU from precision Z- and W-pole measurements at LEP do not lead to stringent bounds.

\subsection*{4.3 $b \to c(u)\tau\nu$}

The violation of LFU in $b \to c\ell\nu$ transitions, measured via the ratios $R_D$ and $R_{D^*}$, sets the scale of NP (or the preferred value of $C_U$). In the PS$^3$ model NP effects in $b \to c(u)\tau\nu$ transitions are described by the following effective operators
\[
\mathcal{L}(b \to u_i\tau\bar{\nu}) = \frac{-4G_F}{\sqrt{2}} \left[ \left[ c_{\nu e u d}^{V,LL}\right]_{333i}^* \right(\tau_L \gamma^\mu \nu_{L3})(\pi_L^i \gamma_\mu b_L) + \left[ c_{\nu e u d}^{S,RL}\right]_{333i}^* \left(\tau_R \nu_{L3}\right)(\pi_L^i b_R) \right], \tag{4.15}\]
where $i = 1(2)$ for up (charm) quarks. At $\Lambda = M_U$ we have to a good approximation
\[
\left[ c_{\nu e u d}^{S,RL}(M_U) \right]_{333i} \approx 2 C_U V_{ib}^*. \tag{4.16}\]
The RG running (due to QCD) introduces an important correction to the scalar operator contributions. To account for these effects we define the following RG factor

\[ C_{\nu Z}^{S,RL}(m_b)_{333i} \approx \eta_S C_{\nu Z}^{S,RL}(M_U)_{333i}. \] (4.17)

Using DsixTools [38] we find \( \eta_S \approx 1.4 \) for \( M_U = 2 \) TeV. On the other hand, the running of the vector operator (which is a conserved current as far as QCD is concerned) is very small and will be neglected in the following discussion.

Due to the presence of a scalar operator, we predict departures from a pure \( V-A \) structure, hence different NP contributions to \( R_D \) and \( R_{D^*} \). We define the relative NP contribution to these observables as

\[ \Delta R_D^{(\ast)} = \frac{R_D^{(\ast)}}{R_D^{SM}} - 1. \] (4.18)

Using the results in [48] for the scalar form factors, we find the following simplified expressions

\[ \Delta R_D \approx 2 C_U \times (1 + 1.5 \eta_S), \]

\[ \Delta R_{D^*} \approx 2 C_U \times (1 + 0.12 \eta_S), \] (4.19)

which imply a 25% (10%) NP effect in \( R_D \) (\( R_{D^*} \)) for \( C_U \approx 0.04 \), i.e. a value around the upper bound of the LFU constraint in Eq. (4.14).

The (non-standard) contributions to \( \bar{B}(B_c \to \tau \nu) \) induced by the scalar operator is chirally enhanced, yielding an enhancement of \( \mathcal{O}(100\%) \) compared to the SM prediction. However, given the low experimental accuracy in this observable, this does not pose any significant bound on the model. Similarly, the modification of the \( B_c \) lifetime, which has been shown to introduce important constraints on explanations of the \( b \to c \tau \nu \) anomalies based on pure scalar operators [49], is well below the experimental limit.

Given the approximate \( U(2)_q \) symmetry, similar NP effects are also expected in \( b \to u \ell \nu \). So far, the most relevant measurement involving these transition is \( \mathcal{B}(B \to \tau \nu) \). Defining

\[ \Delta \mathcal{B}(B \to \tau \nu) = \frac{\mathcal{B}(B \to \tau \nu)}{\mathcal{B}(B \to \tau \nu)^{SM}} - 1, \] (4.20)

we obtain

\[ \Delta \mathcal{B}(B \to \tau \nu) \approx 1 + C_U \left[ 1 + c_d s_b e^{i \phi_b} \frac{V_{tb}}{|V_{ts}|} \Lambda_u \left( 1 + \eta_S \frac{2 m_B^2}{m_\tau (m_b + m_u)} \right) \right]^2 - 1. \] (4.21)

Also in this case scalar contributions are chirally enhanced and we typically expect large NP effects. However, similarly to \( D-\bar{D} \) mixing, in the limit where \( \Delta \alpha_d \to \pi \) (and analogously for \( \alpha_d \to \pi \)) the large phase in \( \Lambda_u \), together with the values of \( s_b \) and \( \phi_b \) required to explain the deficit in \( \Delta \mathcal{B} = 2 \) transitions, yields a significant attenuation of the NP enhancement. The possible range of deviations from the SM is illustrated in Figure [4.3].

Contrary to \( B \) decays, LFU breaking effects in charged-current \( K \) and \( D \) decays are strongly CKM suppressed (relative to the corresponding SM amplitudes) and do not lead to significant constraints.
4.4 \( b \to s \ell \ell \) and \( b \to s \nu \nu \)

The violation of LFU in \( b \to s \ell \ell \) transitions, measured via the ratios \( R_K \) and \( R_{K^*} \), sets the amount of \( U(2)^5 \) breaking in the model which is not directly related to the Yukawa couplings. After imposing the constraints from \( \Delta F = 2 \) observables, the \( Z' \)-mediated contributions to \( b \to s \ell \ell \) amplitudes turn out to be well below those mediated by the vector leptoquark. This is because the \( \Delta F = 2 \) constraints require the effective \( b s Z' \) coupling to be either very small in size or almost purely imaginary (hence with a tiny interference with the SM contribution). As a result, the following approximate relations hold (assuming \( \phi_r = 0 \) and \( \epsilon_U \) real):

\[
\text{Re} (\Delta C^\mu_9) \approx - \text{Re} (\Delta C^{10}_9) \approx - \frac{2 \pi}{\alpha_{\text{em}}} \frac{s_\tau \epsilon_U}{|V_{ts}|} C_U ,
\]

\[
\text{Re} (\Delta C^{\tau\tau}_9) \approx - \text{Re} (\Delta C^{10\tau}_9) \approx \frac{2 \pi}{\alpha_{\text{em}}} \frac{s_\tau \epsilon_U}{|V_{ts}|} C_U ,
\]

where \( \Delta C^\alpha_i = C^\alpha_i - C^\text{SM}_i \), and \( \Delta C^{ee}_9 \approx \Delta C^{ee}_{10} \approx 0 \). Hence, the deviations from unity in the LFU ratios \( R_K \) and \( R_{K^*} \) can be expressed as [50,51]

\[
\Delta R_K = 1 - R_K \mid_{[1.6, \text{ GeV}^2]} \approx 0.23 \Delta C^\mu_9 - 0.23 \Delta C^{10\mu}_9 \approx 0.46 \Delta C^{\mu\mu}_9 \ ,
\]

\[
\Delta R_{K^*} = 1 - R_{K^*} \mid_{[1.1, \text{ GeV}^2]} \approx 0.20 \Delta C^\mu_9 - 0.27 \Delta C^{10\mu}_9 \approx 0.47 \Delta C^{\mu\mu}_9 \ .
\]

Contrary to other models aiming at a combined explanation of the anomalies, we predict \( \text{Re} (\Delta C^\mu_9) \) and \( \text{Re} (\Delta C^{10\tau}_9) \) to be of similar size. This is a consequence of the different \( U(2)^5 \) breaking in the model which is not directly related to the Yukawa couplings. Given that the leading RG effects for the scalar operators are dominated by QCD, the RG running factor for \( C_{S,P} \) and \( \epsilon^{S,P}_{\text{edu}} \) remains the same to a very good approximation.

---

\( ^6 \)Given that the leading RG effects for the scalar operators are dominated by QCD, the RG running factor for \( C_{S,P} \) and \( \epsilon^{S,P}_{\text{edu}} \) remains the same to a very good approximation.
Figure 4.4: Left: $\mathcal{B}(\tau \rightarrow \mu \gamma)$ as function of the NP shift in $R_K$ for different values of $\epsilon_U$. Right: $\mathcal{B}(B^+ \rightarrow K^+\tau^+\mu^-)$ as function of the NP shift in $R_K$ for different values of $s_\tau$.

We also expect relatively large NP enhancement in $\mathcal{B}(B_s \rightarrow \tau\tau)$, dominated by the chirally-enhanced scalar contributions in (4.24). Setting $\Delta C_{9\mu\mu} = -0.6$ and $C_U = 0.04$, and assuming $\phi_b \approx \pi/2$ and $\phi_\tau \approx 0$ we find

$$\frac{\mathcal{B}(B_s \rightarrow \tau\tau)}{\mathcal{B}(B_s \rightarrow \tau\tau)^{\text{SM}}} \approx 4 + 29 \left( \frac{s_b}{0.1 |V_{ts}|} \right)^2,$$

(4.26)

where $\mathcal{B}(B_s \rightarrow \tau\tau)^{\text{SM}} = (7.73 \pm 0.49) \times 10^{-7}$ [55]. We stress the strong correlation between the possible NP contribution to $\Delta B = 2$ amplitudes discussed in Section 4.1 (controlled by $|s_b|$) and a large enhancement in $\mathcal{B}(B_s \rightarrow \tau\tau)$.

Finally, we mention that $b \rightarrow s\nu\nu$ transitions do not get significantly modified in this framework. On the one hand, due to its coupling structure, the vector leptoquark does not contribute at tree-level to such transitions. On the other hand, the $Z'$ contribution is negligible because of the constraints on the $bsZ'$ coupling, as already discussed in the $b \rightarrow s\ell\ell$ case.

### 4.5 LFV processes

We finally turn to LFV processes. Given the unambiguous prediction of a large $\tau \rightarrow \mu$ effective coupling, they represent a striking signature of the model.

In $b \rightarrow s\ell\ell'$ transitions the dominant contribution is mediated by the leptoquark, leading to

$$\text{Re}(C_9^{\mu\tau}) \approx -\text{Re}(C_{10}^{\mu\tau}) \approx -\frac{\text{Re}(\Delta C_9^{\mu\mu})}{s_\tau}, \quad \text{Re}(C_S^{\mu\tau}) = -\text{Re}(C_P^{\mu\tau}) \approx -\frac{2 \eta_s \text{Re}(\Delta C_9^{\mu\mu})}{s_\tau}.$$

(4.27)

Due to the $s_\tau^{-1}$ enhancement, large NP contributions in $\mathcal{B}(B_s \rightarrow \tau\mu)$ and in $\mathcal{B}(B \rightarrow K\tau\mu)$ are expected. In the former case the effect is further reinforced by the chiral-enhancement of scalar
amplitudes, leading to

\[ B(B_s \to \tau^+ \mu^\mp) \approx 2.4 \times 10^{-4} \left( \frac{\Delta R_K}{0.3} \right)^2 \left( \frac{0.1}{s_\tau} \right)^2, \]

\[ B(B^+ \to K^+ \tau^+ \mu^-) \approx 1.2 \times 10^{-5} \left( \frac{\Delta R_K}{0.3} \right)^2 \left( \frac{0.1}{s_\tau} \right)^2, \]

with \( B(B^- \to K^- \tau^- \mu^+) = B(B^+ \to K^+ \tau^+ \mu^-) \) and \( B(B^+ \to K^+ \tau^- \mu^+) \approx 0 \). While there are no experimental constraints in \( B_s \to \tau \mu \) so far, the model prediction for \( B^+ \to K^+ \tau^+ \mu^- \) lies close to the current experimental limit by BaBar: \( B(B^+ \to K^+ \tau^+ \mu^-) < 2.8 \times 10^{-5} \) (90% CL) [56]. In figure 4.4 (right) we show the predicted values of \( B(B^+ \to K^+ \tau^+ \mu^-) \) as a function of the NP shift in \( R_K \) and for different benchmark values of \( s_\tau \).

In purely leptonic decays the most interesting observable is \( \tau \to \mu \gamma \). Radiative LFV decays are generated at the one loop level, both by \( Z' \) and \( U \) loops. The leptoquark yields the largest contribution due to its larger couplings and the \( m_\mu \)-enhancement of the loop function. From the explicit one-loop calculation (see appendix D.1), we find

\[ B(\tau \to \mu \gamma) \approx 3.8 \times 10^{-8} \left( \frac{\Delta R_K}{0.3} \right)^2 \left( \frac{0.01}{\epsilon_U} \right)^2, \]

which is just below the current experimental limit set by BaBar: \( B(\tau \to \mu \gamma) < 4.4 \times 10^{-8} \) (90% CL) [57]. In figure 4.4 (left) we show the prediction for \( B(\tau \to \mu \gamma) \) as a function of the NP contribution to \( R_K \) for different values of \( \epsilon_U \). The model also predicts a sizable NP contribution to \( \tau \to 3\mu \), mediated by a tree-level \( Z' \) exchange. We obtain the following approximate expression

\[ B(\tau \to 3\mu) \approx C_{Z'}^2 s_\tau^2 \left[ 28 (s_\tau^2 + \epsilon_\ell)^2 - 38 \left( \frac{g_1}{g_4} \right)^2 \left( s_\tau^2 + \epsilon_\ell - 2 \left( \frac{g_1}{g_4} \right)^2 \right) \right]. \]

For typical values of the model parameters, this contribution lies about one order of magnitude below the current experimental limit by Belle: \( B(\tau \to 3\mu) < 1.1 \times 10^{-8} \) (90% CL) [58]. However, this conclusion is strongly dependent on the precise value of \( s_\tau \).

Purely leptonic LFV transitions of the type \( \mu \to e \) are controlled by the mixing angle \( s_\ell \) in Eq. (A.20). We find that the most stringent constraint on this angle is obtained, at present, by the experimental bound on \( \mu \to 3e \) set by the Sindrum Collaboration: \( B(\mu \to 3e) < 1.0 \times 10^{-15} \) (90% CL) [59]. Similarly to \( \tau \to 3\mu \), also \( \mu \to 3e \) is dominated by the tree-level exchange of the \( Z' \), which yields

\[ B(\mu \to 3e) \approx 420 C_{Z'}^2 \left( \frac{g_1}{g_4} \right)^4 s_\ell^2 (s_\ell + s_\tau^2)^2 \]

\[ \approx (1 - 10) \times 10^{-14} \left( \frac{s_\ell}{0.01} \right)^2 \left( \frac{\epsilon_\ell + s_\tau^2}{0.02} \right)^2. \]

where the range in the second numerical expression reflects the uncertainty on the \( Z' \) mass and couplings. Assuming \( \epsilon_\ell \sim \epsilon_U \sim \mathcal{O}(10^{-2}) \), and taking natural values for the other parameters, we find

\[ s_\ell \lesssim 10^{-2}, \]

(4.32)
consistently with the EFT estimate derived in \[14\]. Another important constraint on \( s_e \), which however depends also on \( \theta_{\tau \mu}^R \), is provided by \( \mu \to e \gamma \). As in \( \tau \to \mu \gamma \), contributions to this observable appear in our model at one loop, with the dominant effect being mediated by the leptoquark. We find

\[
\mathcal{B}(\mu \to e \gamma) \approx 6 \times 10^{-13} \left( \frac{\Delta R_K}{0.3} \right)^2 \left( \frac{0.01}{\epsilon_U} \right)^2 \left( \frac{s_e}{0.01} \right)^2 \left( \frac{|\theta_{\tau \mu}^R|}{0.01} \right)^2 ,
\]

(4.33)
to be compared with the bound by the MEG Collaboration: \( \mathcal{B}(\mu \to e \gamma) < 4.2 \times 10^{-13} \) (90\% CL) [60]. Other limits on this angle are significantly weaker. In particular, from the \( Z' \) contribution to \( \mu \tilde{e} \tilde{d} \) effective operators, which are constrained by \( \mu \to e \) conversion [61, 62], we get \( s_e \lesssim 10^{-1} \).

On the other hand, the leading contribution to \( \mu \tilde{e} \tilde{d}(t) \) effective operators is due to the leptoquark exchange, and the dominant constraint is set by \( K_L \to \mu e \) [62]. In this case the amplitude is (formally) independent from \( s_e \), but it depends on the subleading \( U(2)_l \) breaking parameter \( \Delta \epsilon_U \), defined in Eq. \[B.4\]:

\[
\mathcal{B}(K_L \to \mu^\pm e^\mp) \approx 1.6 \times 10^{-5} (\Delta \epsilon_U)^2 \left( \frac{\Delta R_K}{0.3} \right)^2 \left( \frac{0.1}{s_\tau} \right)^2 .
\]

(4.34)
Using the current experimental bound by the BNL Collaboration, \( \mathcal{B}(K_L \to \mu^\pm e^\mp) = 0.47 \times 10^{-11} \) (90\% CL) [63], we find

\[
\Delta \epsilon_U \lesssim 4 \times 10^{-4} .
\]

(4.35)
This bound is consistent with the naive estimate of this parameter, \( \Delta \epsilon_U = \mathcal{O}(\epsilon_U s_e s_d) \), provided \( s_e \) satisfies the bound in Eq. \[4.32\].

5 Low-energy fit and discussion

In order to precisely quantify the log-likelihood of the proposed model in the description of the anomalies, we perform a fit to low-energy data. We work in the minimal breaking scenario presented in Section 2.2 and set \( \Delta \alpha_d = \pi \) to minimize undesired NP contributions in \( \mathcal{B}(B \to \tau \nu) \) and \( \Delta F = 2 \) transitions, as discussed in Section 4. We also restrict ourselves to the case \( s_e = 0 \), hence to vanishing LFV in \( \mu \to e \) transitions, given that this parameter has no impact on the description of the anomalies. Under these assumptions, the following model parameters have a relevant impact at low energies: \( \omega_1, \omega_3, s_\tau, \epsilon_R^e, s_b, \phi_b, \epsilon_U \)\footnote{Despite stringent, the bound on \( s_e \) in \[4.32\] is not unnatural. The benchmark for subleading \( U(2)_l \) breaking terms not aligned to the second generation is provided by \( (m_\tau / m_\mu)^{1/2} \approx 7 \times 10^{-2} \).} The first two are related to the NP scale while, the other five control the breaking of the \( U(2)_l \) symmetry. We perform a Bayesian estimation for these parameters using the log-likelihood

\[
\log \mathcal{L} = -\frac{1}{2} \sum_{i \in \text{obs}} \left( \frac{x_{i}^{\text{PS}} - x_{i}^{\text{exp}}}{\sigma_i} \right)^2 ,
\]

(5.1)

\footnote{In order to remove marginally relevant parameters we fix \( \epsilon_q = \epsilon_\ell = \epsilon_U \). We have checked explicitly that departing from this restriction, while keeping \( \epsilon_q \) and \( \epsilon_\ell \) within their expected range, has no effect on fit results. We also set \( \phi_\tau \) to zero and treat \( \epsilon_\ell \) and \( \epsilon_R^e \) as real parameters, since these extra phases do not introduce any interesting features. Finally, we conservatively assume \( \epsilon_R^d = 0 \); a non-zero value for this parameter would slightly improve the agreement with \( \Delta F = 2 \) data.}

20
Figure 5.1: 68% (dark blue) and 95% (light blue) posterior probabilities of $\phi_b$ and $s_b$ (left), $\epsilon_U$ and $s_\tau$ (mid), and of $\epsilon_R^e$ and $s_\tau$ (right).

constructed from the observables listed in Tables D.1, D.3, D.4 and D.6 and using the expressions in appendix D for the model predictions. For the CKM matrix elements we take the values reported in the NP fit from UTFit and for the remaining input parameters we use PDG values [64]. For the Bayesian analysis we use the nested sampling algorithm implemented in the public package MultiNest [65–67]. The resulting posterior probabilities are analysed using the Markov Chain sample analysis tool GetDist [68]. In the analysis we consider flat priors in all the parameters for the following ranges

\[
\begin{align*}
\omega_1 &\in [0.3, 1.5] \text{ TeV}, & \omega_3 &\in [0.3, 1.5] \text{ TeV}, & s_\tau &\in [0, 0.15], \\
s_b &\in [-0.1, 0.1], & \phi_b &\in [0, \pi], & \epsilon_R^e &\in [-0.01, 0.01], \\
\epsilon_U &\in [0, 0.02].
\end{align*}
\]

We obtain the following 68% probability ranges for the model parameters extracted from the marginalized posterior probabilities

\[
\begin{align*}
\omega_1 &= 1.0 \pm 0.3 \text{ TeV}, & \omega_3 &= 1.2 \pm 0.2 \text{ TeV}, & s_\tau &= 0.10 \pm 0.03, \\
s_b &= (0.07 \pm 0.06) |V_{ts}|, & \phi_b &= (0.55 \pm 0.18) \pi, & \epsilon_R^e &= (0.11 \pm 0.03) \frac{m_\mu}{m_\tau}, \\
\epsilon_U &= (1.2 \pm 0.3) \times 10^{-2}.
\end{align*}
\]

In figure 5.1, we show the 68% and 95% two-dimensional posterior probabilities for $s_b$ and $\phi_b$, $\epsilon_U$ and $s_\tau$, and for $\epsilon_R^e$ and $s_\tau$. As can be seen, there is a clear correlation between the phase $\phi_b$ and the maximum allowed value for $s_b$. We also find that positive values of $s_b$ are preferred. This behaviour is expected from the discussion in the previous section: while the size of $s_b$ and preferred value for $\phi_b$ are connected to the (negative) NP contribution to $\Delta F = 2$, the preference for a positive $s_b$ is related to the partial cancellations in $D \rightarrow \bar{D}$ mixing and $B(B \rightarrow \tau \nu)$. On the other hand, the anti-correlation between $\epsilon_U$ and $s_\tau$ can be easily understood from the fact that the NP contribution in $b \rightarrow s \ell \ell$ transitions is proportional to the product of these two parameters, i.e. $\text{Re} (\Delta C_9^{\mu}) \approx - \text{Re} (\Delta C_{10}^{\mu}) \propto C_U s_\tau \epsilon_U$. Finally, we find a

\[\text{Since the observables considered in the fit are not sensitive to the individual signs of } \epsilon_U \text{ and } s_\tau \text{ but only to their product, there is a double degeneracy in the fit. We remove this degeneracy by considering both } \epsilon_U \text{ and } s_\tau \text{ to be positive.} \]
significant correlation between $\epsilon_R^s$ and $s_\tau$. As shown in the previous section, a mild cancellation 
(at the level of 20%) among these two parameters is required to ensure a sufficiently small $\theta_B^\tau_{\mu\mu}$, as indicated by $B(B_s \to \mu\mu)$ and $B(\mu \to e\gamma)$. Note that, beside the smallness of $s_\tau$ compared to $|V_{ts}|$, the other three mixing parameters ($\epsilon_U$, $s_\tau$, and $\epsilon_R^s$) turn out to have magnitudes in 
good agreement with their natural parametric size.

Concerning low energy observables, we reach similar conclusions to those already discussed 
in Section 4 in terms of simplified analytical expressions. In Figure 5.2 we show the 68% and 95% posterior probabilities for $\Delta R_{D^{(*)}}$ and $\Delta R_K$. As can be seen, the model can fully 
accommodate the anomalies in $b \to s\ell\ell$. However, as anticipated in Section 4, the complete explanation of the $R_{D^{(*)}}$ anomalies within this framework is limited by LFU tests in $\tau$ decays. From the fit we obtain a NP enhancement of around 7%–8% for $R_D$ and 18%–22% for $R_D^*$.

As already emphasized in Section 4, in our setup the explanation of the anomalies implies 
large LFV effects in $\tau \to \mu$ transitions, in particular in $\tau \to \mu\gamma$, $\tau \to 3\mu$, $B \to K\tau\mu$, and $B_s \to \tau\mu$. Interestingly, we find that the NP effects in $\tau \to \mu\gamma$ are anti-correlated to those in $B_s \to \tau\mu$ (and $B \to K\tau\mu$), allowing us to directly connect the product of these LFV rates to the NP enhancement in $R_{D^{(*)}}$ and $b \to s\ell\ell$. More precisely, we find the following relations 
among NP observables

$$\left(\frac{\Delta R_D}{0.2}\right)^2 \left(\frac{\Delta R_K}{0.3}\right)^2 \approx 3 \left[ \frac{B(B \to K\tau^+\mu^-)}{3 \times 10^{-5}} \right] \left[ \frac{B(\tau \to \mu\gamma)}{5 \times 10^{-8}} \right],$$

(5.4)

which hold almost independently from any model parameter. This is illustrated in Figure 5.3 (left) where we show the 68% and 95% posterior probabilities for $B(\tau \to \mu\gamma)$ and $B(B \to K\tau\mu)$. We see that the model predictions for these two observables are close to their experimental 
bounds shown in the red bands, as implied by the expressions in (5.4). A partial anti-correlation is 
present also between $\tau \to 3\mu$ and LFV in $B$ decays, as illustrated in Figure 5.3 (right). However, in this case the effect is diluted by the uncertainty on $Z'$ mass and couplings, which are not strongly constrained by other observables.

As a final comment, it is worth stressing that this low-energy fit does not pose stringent 
constraints on the masses of the heavy vector bosons. The low-energy observables constrain only 
the effective Fermi couplings in Eq. (2.19), or $\omega_{1,3}$. Still, we can derive a well-defined range for vector boson masses taking into account that $g_U \gg g_\omega$: setting $2.5 \leq g_U \leq 3.0$, the masses of $Z'$, $U$, and $G'$ range between 2 and 3 TeV.

6 Conclusions

The main idea behind the PS$^3$ model is that the flavor universality of strong, weak, and 
electromagnetic interactions observed at low energies is only a low-energy property: the ultraviolet 
completion of the SM is a theory where gauge interactions are completely flavor non-universal, 
with each fermion family being charged under its own gauge group. The motivation for this hypothesis, and the explicit construction of the PS$^3$ model presented in Ref. 1, is twofold: it explains the pattern of anomalies recently observed in $B$ meson decays and, at the same time, the well-known hierarchical structure of quark and lepton mass matrices. These two phenomena turn out to be closely connected: they both follow from the dynamical breaking of the flavor non-universal gauge structure holding at high energies down to the SM.
Figure 5.2: 68% (dark blue) and 95% (light blue) posterior probabilities of the NP shifts in $R_D^*$ vs. $\Delta R_K$. The experimental values at 1\(\sigma\) (2\(\sigma\)) are indicated by the dark (light) coloured bands.

Figure 5.3: Left: 68% (dark blue) and 95% (light blue) posterior probabilities of $\mathcal{B}(\tau \rightarrow \mu \gamma)$ and $\mathcal{B}(B^+ \rightarrow K^+\tau^+\mu^-)$ from the global fit. The black lines denote the 95% posterior probabilities fixing $\Delta R_K = -0.3$ (solid) and $\Delta R_K = -0.2$ (dashed). The red bands show the 90% CL exclusion limits for these observables. Right: 68% (dark blue) and 95% (light blue) posterior probabilities of $\mathcal{B}(\tau \rightarrow 3\mu)$ and $\mathcal{B}(B_s \rightarrow 3\mu)$ from the global fit.
On general grounds, low-energy observables put very stringent constraints on flavor non-universal interactions mediated by TeV-scale bosons, as expected in the PS$^3$ model. In this paper we have presented a comprehensive analysis of such constraints, and the corresponding implications for future low-energy measurements. As far as the constraints are concerned, we confirm the main conclusions of Ref. [1]: i) the model is in very good agreement with all existing bounds, without significant tuning of its free parameters; ii) the model could account for the $B$ anomalies, reaching the 1σ range of all the present measurements with the exception of $R_{D^*}$, where the maximal allowed deviation from the SM does not exceed the 10% level. In addition, we have shown that the model can slightly improve the description of $\Delta F = 2$ observables with respect to the SM.

The most interesting aspect of this analysis is related to the possible implications of the PS$^3$ model in view of future low-energy measurements. We have shown that a remarkable feature is the prediction of sizeable rates for LFV processes of the type $\tau \to \mu$, both in $B$ decays (such as $B \to K\tau\mu$ and $B_s \to \tau\mu$) as well as in $\tau$ decays (most notably $\tau \to \mu\gamma$ and $\tau \to 3\mu$). The fact that the $B$ anomalies could naturally imply large LFV effects in $B$ decays was first pointed out in Ref. [69], on the basis of general considerations. The PS$^3$ model provides an explicit realization of this mechanism, predicting in addition a strict anti-correlation between $\tau \to \mu\gamma$ and $b \to s\tau\mu$ transitions, illustrated in Figure 5.3, that can be viewed as a distinctive signature. As we have shown in Section 4.5, also $\mu \to 3e$, $\mu \to e\gamma$, and $K_L \to \mu e$ decays could be close to their present exclusion limits; however, this conclusion is less strict given the uncertainty on the $\mu \to e$ mixing, which is not constrained by the anomalies.

Besides LFV processes, we have shown that the model predicts interesting non-standard effects in $\Delta F = 1$ and $\Delta F = 2$ observables, with non-trivial correlations. Particularly relevant and distinctive are the predictions for the violations of LFU in charged currents illustrated in Figure 4.3: the presence of right-handed currents implies $\Delta R_D \approx 2.6 \Delta R_{D^*}$ and a possible large enhancement of $B(B \to \tau\nu)$ ranging from 30% up to 100% of the SM prediction.

Most of the predictions for low-energy observables presented in this work differ with respect to what is expected in other models proposed for a combined explanation of the $B$ anomalies. The corresponding measurements would therefore be of great value in shedding light on the dynamics behind the anomalies, if unambiguously confirmed as due to physics beyond the SM, and clarify their possible link to the origin of quark and lepton masses.

A Structure of the SM Yukawa couplings in PS$^3$

Within our model the complete set of Yukawa couplings, i.e. the couplings of the chiral fermions to the scalar field responsible for the breaking of the electroweak symmetry, is generated only after the SM$^{1+2} \times \text{PS}_3 \to \text{SM}$ symmetry breaking. Below such scale, adopting the SM notation, we define the couplings as

$$L = \bar{q}_L^i (Y_d)_{ij} d_R^j \phi + \bar{q}_L^i (Y_u)_{ij} u_R^j \phi^c + \bar{e}_L^i (Y_e)_{ij} e_R^j \phi + \text{h.c.}, \quad (A.1)$$
where \(i,j = 1,2,3\) and \(\phi\) is the effective SM Higgs field (normalized such that \(\langle\phi^\dagger\phi\rangle = v^2/2\), with \(v = 246\) GeV).

As discussed in Section 2.2, we can decompose each Yukawa coupling as follows

\[
Y_f = y_f \begin{pmatrix} \epsilon_{LR}^f & \epsilon_L^f \nu_R^\dagger \end{pmatrix} V_L, \tag{A.2}
\]

where \(V_L\) and \(V_R\) are unit vectors in the \(U(2)^{q+\ell}\) and \(U(2)^{u+d+e}\) space, and \(X_{LR}\) is a \(2 \times 2\) non-hermitian matrix satisfying \(\text{Tr}(X_{LR}X_{LR}^\dagger) = 1\). Since non-vanishing \(\epsilon_{LR}^f\), \(\epsilon_L^f\), \(\epsilon_R^f\) are induced by operators with \(d = 5, 6, 7\), respectively, on general grounds we expect \(|\epsilon_{LR}^f| \ll |\epsilon_L^f| \ll |\epsilon_R^f| \ll 1\).

Without loss of generality, we can work in the flavor basis where

\[
V_L \rightarrow \hat{n}_2 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \tag{A.3}
\]

i.e. in the basis where the left-handed second generation is defined by the orientation in flavor space of the link fields \(\Omega_3\) and \(\Omega_1\). This is what we conventionally define as the interaction basis for the left-handed doublets. We can use the freedom on the right-handed sector to set \(X_{LR}\) in the form \(U \times \text{diag}(0,1)\), where \(U\) is a unitary matrix. The null eigenvalue of \(X_{LR}\), corresponding to the limit of massless first generation, can be lifted by introducing additional link fields, with subleading VEVs. The inclusion of such terms effectively amount to change \(X_{LR}\) into a Yukawa-dependent term \(\Delta_f\) of the form

\[
X_{LR} \rightarrow U_f^\dagger \Delta_f, \quad \Delta_f = \text{diag} \left( \frac{m_f^1}{m_f^2}, 1 \right), \tag{A.4}
\]

where \(U_f\) is a (complex) unitary matrix. In the limit where the \(U(2)^5\) breaking in the right-handed sector is induced by a single field (\(\Phi_R\) in the minimal set-up), then \(d = 6\) and \(d = 7\) terms are aligned in the right-handed sector. This implies \(V_R \rightarrow \hat{n}_2\) in the basis defined by Eq. (A.4).

In such basis, the quark Yukawa matrices assume the explicit form

\[
Y_u = y_t \begin{pmatrix} e_{LU}^u U_{LU}^\dagger \Delta_u & e_{LU}^u \hat{n}_2 \\ e_{RU}^u \hat{n}_2 \end{pmatrix}, \quad Y_d = y_b \begin{pmatrix} e_{LR}^d U_{LR}^\dagger \Delta_d & e_{LR}^d \hat{n}_2 \\ e_{RR}^d \hat{n}_2 \end{pmatrix}. \tag{A.5}
\]

Following the discussion of CP phases in Ref. [9], without loss of generality we can set \(\epsilon_{LR}^f\) to be real (contrary to \(\epsilon_L^f\) and \(\epsilon_R^f\)) and decompose the \(2 \times 2\) matrix \(U_f\) as

\[
U_f = \begin{pmatrix} c_f & s_f e^{i\alpha_f} \\ -s_f e^{-i\alpha_f} & c_f \end{pmatrix}. \tag{A.6}
\]

In the following we assume that \(s_f \ll 1\), as naturally implied by the absence of fine-tuning in deriving the CKM matrix.

In the phenomenological analysis we employ the down-type quark and the charged-lepton mass-eigenstate basis for the SM fermions, where the \(SU(2)_L\) structure of the left-handed doublets is given by

\[
q_L^i = \left( \begin{array}{c} V_{k_i}^* u_k \\ d_i \end{array} \right), \quad \ell_L^i = \left( \begin{array}{c} \nu_i \\ e_i \end{array} \right), \tag{A.7}
\]

25
with $V_{ki}$ being the elements of CKM matrix. We move from the interaction basis to this basis by performing the rotation

$$q_L|\text{int} = L_d \times q_L|\text{d-basis}, \quad \ell_L|\text{int} = L_e \times \ell_L|\text{e-basis}. \quad (A.8)$$

More generally, we denote by $X_a$ (with $X = L, R$ and $a = u, d, e$) the unitary matrices that bring the Yukawa couplings in diagonal form (starting from the interaction basis),

$$L_d^* Y_u R_u = \text{diag}(y_{u1}, y_{u2}, y_{u3}), \quad L_d^* Y_d R_d = \text{diag}(y_{d1}, y_{d2}, y_{d3}), \quad L_e^* Y_e R_e = \text{diag}(y_{e1}, y_{e2}, y_{e3}), \quad (A.9)$$

where the $y_i$ are real and positive and $V_{\text{CKM}} = L_u^* L_d$.

The $X_a$ have non-trivial flavor-blind phases $[\det(X_a) = e^{i\phi X}]$. The electroweak symmetry implies $\phi_d^L = \phi_u^L$, and three relative phases corresponding to unbroken global symmetries (hypercharge, lepton number, baryon number) are unobservable. Of the two remaining phases one combination affects the relative phase between the leptoquark couplings $\beta_q$ and $\beta_d$, and is potentially observable. Following Ref. [1], we fix this phase by the condition $(\beta_q)_{33} = -(\beta_d)_{33}$ which allows us to maximize the contribution to $\Delta R_D$. Having fixed this phase, in the following we set $\det(X_u) = 1$.

**Left-handed rotations in the quark sector.** To a very good approximation, the left-handed diagonalization matrices have the form

$$L_d^L = R_{12}(s_d; \alpha_d) \times R_{23}(s_b; \phi_b), \quad L_u^L = R_{12}(s_u; \alpha_u) \times R_{23}(s_t; \phi_t), \quad (A.10)$$

where

$$R_{12}(s_d; \alpha_d) = \begin{pmatrix} U_d & 0 \\ 0 & 1 \end{pmatrix}, \quad R_{23}(s_b; \phi_b) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & c_b & s_b e^{i\phi_b} \\ 0 & -s_b e^{-i\phi_b} & c_b \end{pmatrix}, \quad (A.11)$$

with $s_b/c_b = |e_f^d|$ and $\phi_b = \arg(e_f^d)$, and similarly for the up sector. As we discuss next, three out of the four real mixing parameters $(s_b, s_d, s_t, s_u)$ appearing in these matrices can be expressed in terms of CKM elements. Concerning the four phases $(\phi_b, \alpha_d, \phi_t, \alpha_u)$, one is unphysical and one can be expressed in terms of the CKM phase $\gamma$.

The CKM matrix is $V_{\text{CKM}} = L_u^L L_d^L$, implying

$$V_{\text{CKM}} = \begin{pmatrix} U_d & 0 \\ 0 & 1 \end{pmatrix} \times R_{23}(s; \xi) \times \begin{pmatrix} U_d^L & 0 \\ 0 & 1 \end{pmatrix} \quad (A.12)$$

where $(s/c)e^{i\xi} = s_b e^{-i\phi_b} - s_t e^{-i\phi_t}$. To match this structure with the standard CKM parametrization, we rephase it by imposing real $V_{ud}, V_{us}, V_{cb}, V_{tb}, V_{cs}$ (which is real at the level of approximation we are working, namely up to corrections of $O(\lambda^2)$ relative to the leading term for each of CKM entry), obtaining

$$V_{\text{CKM}} = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & s_u s e^{-i\delta} \\ -\lambda & 1 - \lambda^2/2 & c_u s \\ -s_d s e^{i(\delta + \alpha_u - \alpha_d)} & -s c_d & 1 \end{pmatrix}, \quad (A.13)$$

where the phase $\delta$ and the real and positive parameter $\lambda$, are defined by

$$\lambda e^{i\delta} = s_u c_d - c_u s_d e^{-i(\alpha_u - \alpha_d)} \quad (A.14)$$

26
Hence it follows that the three mixing angles \( s_u, s_d, \) and \( s \) can be determined completely in terms of three independent CKM elements:

\[
s = |s_t - s_b e^{i(\phi_t - \phi_b)}| = |V_{cb}|, \quad \frac{s_u}{c_u} = \frac{|V_{ub}|}{|V_{cb}|}, \quad \frac{s_d}{c_d} = \frac{|V_{td}|}{|V_{ts}|}.
\]  

(A.15)

As far as the phases are concerned, we find

\[
\delta = -\arg(V_{ub}) \equiv \gamma, \quad \alpha_u - \alpha_d = \arg(V_{td}) + \arg(V_{ub}) \approx -\pi/2,
\]

(A.16)

where the last relation follows, to a very good accuracy, from the numerical values of the CKM inputs.

Flavor mixing in the left-handed sector is therefore controlled by the matrix \( L_d \) that contains only three free parameters (the real mixing angle \( s_b \) and the unconstrained phases \( \phi_b \) and \( \alpha_d \)):

\[
L_d = R_{23}(-s_b; \phi_b)R_{12}(-s_d; \alpha_d) = \begin{pmatrix}
\frac{c_d}{s_d} e^{-i\alpha_d} & -\frac{s_d}{c_d} e^{i\alpha_d} & 0 \\
-s_d e^{i\phi_b} & c_d & -s_b e^{i\phi_b} \\
0 & s_b c_d e^{-i\phi_b} & 1
\end{pmatrix},
\]

(A.17)

where \( s_d \) is fixed by Eq. (A.15) and, consistently with the approximations so far performed, we have set \( c_b = 1 \).

Right-handed rotations in the quark sector. The structure of the right-handed rotation matrices is simpler, being confined to the 2-3 sector in the limit where we neglect tiny terms of \( \mathcal{O}(m_f^1/m_j^3, (\epsilon^f_{LR})^2) \). We find

\[
R_d = \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & -\frac{m_l}{m_b} s_b e^{-i\phi_b}
\end{pmatrix}
\]

\[
\left(\epsilon_R^d \right)^* - \frac{m_l}{m_b} s_b e^{-i\phi_b}
\]

\[
\equiv \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & \theta_{bs}^R \\
0 & -\left(\theta_{bs}^R\right)^* & 1
\end{pmatrix},
\]

(A.18)

\[
R_u = \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & -\frac{m_l}{m_t} s_t e^{-i\phi_t}
\end{pmatrix}
\]

\[
\left(\epsilon_R^u \right)^* - \frac{m_l}{m_t} s_t e^{-i\phi_t}
\]

\[
\equiv \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & \theta_{tc}^R \\
0 & -\left(\theta_{tc}^R\right)^* & 1
\end{pmatrix}.
\]

(A.19)

Note that if we neglect the effect of \( d=7 \) effective operators (i.e. for \( \epsilon_{LR}^{u,d} \to 0 \)), these matrices do not contain additional free parameters (i.e. they are completely determined in terms of angles and phases appearing already in the left-handed sector).

Rotations in the lepton sector. Given the model-dependence on the neutrino mass matrix, in the left-handed sector we cannot eliminate parameters in terms of known mixing angles; moreover, the strong constraints on the \( \mu \to e \) transitions imply that the 1-2 mixing terms are very small. Proceeding as above, and neglecting higher-order terms in the 1-2 mixing, we thus decompose the left-handed rotation mixing matrix as

\[
L_e = \begin{pmatrix}
1 & s_e e^{i\alpha_e} & 0 \\
-s_e e^{-i\alpha_e} & 1 & s_e e^{i\phi_e} \\
s_e s_t e^{-i(\alpha_e + \phi_e)} & -s_t e^{-i\phi_e} & 1
\end{pmatrix}.
\]

(A.20)

In the right-handed sector, proceeding in full analogy with the quark case we get

\[
R_e = \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & \theta_{\mu\tau}^R \\
0 & -\left(\theta_{\mu\tau}^R\right)^* & 1
\end{pmatrix}
\]

\[
\left(\epsilon_R^e \right)^* + \frac{m_\mu}{m_\tau} s_\tau e^{-i\phi_\tau}
\]

\[
\equiv \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & \theta_{\mu\tau}^R \\
0 & -\left(\theta_{\mu\tau}^R\right)^* & 1
\end{pmatrix}.
\]

(A.21)
B Generation of the $U(2)^5$-breaking effective operators

An example of dynamical generation of the $U(2)^5$-breaking effective operators appearing in $\mathcal{L}^{d=5}_{\Omega}$ and $\mathcal{L}^{d=6}_{\Omega}$, defined in Eqs. (2.7) and (2.9), is obtained by introducing a pair of vector-like fermions, $\chi^i_{L/R} \sim (4, 2, 1)_i$, $i = 1, 2$, coupled to the SM leptons and quarks via

$$-\mathcal{L}_\chi \supset M_\chi \hat{\chi}_L^i \chi_R^i + \lambda_1 \tilde{e}_L^i \Omega_1 \chi_R^i + \lambda_3 \tilde{q}_L \Omega_3 \chi_R^i + \lambda_H \tilde{c}_L^i H_1 \Psi_R^3 + \lambda_H^c \chi_L^c \hat{H}_1^c \Psi_R^3 + h.c. ,$$

where $\Psi_R^3$ denotes the complete right-handed multiplet charged under PS$_3$. Assuming the vector-like fermions to be heavy, we can integrate them out obtaining the following tree-level expressions for the coefficients of the $\mathcal{L}^{d=5}_{\Omega}$ operators:

$$\frac{y_{q3}}{\Lambda_{23}} = \frac{\lambda_3 \lambda_H}{M_\chi}, \quad \frac{y_{e3}}{\Lambda_{23}} = \frac{\lambda_1 \lambda_H}{M_\chi}, \quad \frac{y'_{q3}}{\Lambda_{23}} = \frac{\lambda_3 \lambda_H^c}{M_\chi}, \quad \frac{y'_{e3}}{\Lambda_{23}} = \frac{\lambda_1 \lambda_H^c}{M_\chi}. $$

Similarly, in the case of the $\mathcal{L}^{d=6}_{\Omega}$ operators we get

$$\epsilon_U = c_{qL} \frac{\omega_1 \omega_3}{2 \Lambda_{23}^2} = \frac{\lambda_3 \omega_1^2 \omega_3}{2 M_\chi^2} , \quad \epsilon_{\ell} = c_{\ell\ell} \frac{\omega_1^2}{2 \Lambda_{23}^2} = \frac{|\lambda_1|^2 \omega_1^2}{2 M_\chi^2} , \quad \epsilon_q = c_{qq} \frac{\omega_3^2}{2 \Lambda_{23}^2} = \frac{|\lambda_3|^2 \omega_3^2}{2 M_\chi^2} .$$

If the vector-like mass is of $\mathcal{O}(\Lambda_{23})$, namely $M_\chi = \text{few} \times 10$ TeV, then the $\lambda_i$ should assume $\mathcal{O}(1)$ values to recover numerically correct entries for the Yukawa couplings. In this case the $\epsilon_i$ turn out to be of $\mathcal{O}(10^{-3})$. Alternatively, lowering the vector-like mass to $M_\chi = \mathcal{O}(1$ TeV), which is still compatible with high-energy phenomenology, the $\lambda_i$ turn out to be of $\mathcal{O}(10^{-1})$ and the $\epsilon_i$ can rise up to $\mathcal{O}(10^{-2})$. We thus conclude that the natural range for the parameters controlling the $U(2)^5$ breaking of the TeV-scale vectors is $10^{-3} \lesssim |\epsilon_{\ell, q, U}| \lesssim 10^{-2}$.

In the limit $\lambda_i \rightarrow 0$, the inclusion of the vector-like fermions enlarges the flavor symmetry of the model to $U(2)^5 \times U(2)_\chi$. The minimal breaking structure for the spurions discussed in section 2.2 is achieved by choosing the coupling $\lambda_3$ to leave the subgroup $U(2)_{H+\chi}$ unbroken. This subgroup is however broken in other sectors, in particular by the couplings of the vector-like fermions to the Higgs. As a result, the minimal breaking structure receives subleading corrections when considering products of more spurions. These subleading effects are specially relevant in two cases i) $U(2)_q$ violating terms in the $Z'$ and $G'$ couplings to quarks, which are severely constrained by $\Delta F = 2$ amplitudes; ii) non-vanishing entries of the $U$ couplings involving the first family, which are severely constrained by $K_L \to \mu e$. In these cases one finds

$$N^L_G (N^L_Z) \rightarrow N^L_G (N^L_Z) \big|_{U(2)_{H+\chi}} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & \Delta \epsilon_q & \tilde{\epsilon}_q \\ 0 & \tilde{\epsilon}_q^* & 0 \end{pmatrix} , \quad \Delta \epsilon_q = \mathcal{O}(\epsilon_U^2), \quad \tilde{\epsilon}_q = \mathcal{O}(\epsilon_U s_\tau),$$

$$N^L_U \rightarrow \begin{pmatrix} \Delta \epsilon_{\ell} & \tilde{\epsilon}_U^d & 0 \\ \tilde{\epsilon}_U^d & \epsilon_{\ell} & 0 \\ 0 & 0 & 1 \end{pmatrix} , \quad \Delta \epsilon_{\ell} = \mathcal{O}(\epsilon_U s_{\ell s_d}), \quad \tilde{\epsilon}_U^d = \mathcal{O}(\epsilon_U s_d), \quad \tilde{\epsilon}_U = \mathcal{O}(\epsilon_U s_\ell).$$

(B.4)
Using the expressions in \[70, 71\], we find the following result for the branching ratio for \(\ell\ell\gamma\gamma\) in what follows we describe the corresponding theory expressions.

The full list of experimental values for the LFV observables included in the fit is provided in Table D.1. In what follows we describe the corresponding theory expressions. In Tables C.2, C.4 and C.3 we provide the matching conditions of the \(Z'\), \(G'\) and \(U\) to the SMEFT, following the prescriptions described in Section 3.1. We list the operators including right-handed neutrinos in Table C.1, while for the other operators we use the same basis as in 33.

## C Wilson coefficients of the SMEFT

In Tables C.2, C.4 and C.3 we provide the matching conditions of the \(Z'\), \(G'\) and \(U\) to the SMEFT, following the prescriptions described in Section 3.1. We list the operators including right-handed neutrinos in Table C.1, while for the other operators we use the same basis as in 33.

## D Low energy observables and NP contributions

In this section we list all the low-energy observables considered in the phenomenological analysis together with their theory expressions and experimental values.

### D.1 LFV observables

The full list of experimental values for the LFV observables included in the fit is provided in Table D.1. In what follows we describe the corresponding theory expressions.

\(\ell_\alpha \to \ell_\beta \ell_\gamma \ell_\gamma\). LFV decays of the type \(\ell_\alpha \to \ell_\beta \ell_\gamma \ell_\gamma\) are described in our model by the effective Lagrangian

\[
\mathcal{L}(\ell_\alpha \to \ell_\beta \ell_\gamma \ell_\gamma) = - \frac{4G_F}{\sqrt{2}} \left( \left[ C_{ee}^{V,LL} \right]_{\alpha \beta \gamma \gamma} (\bar{\ell}_L^\gamma \gamma \ell_R^\alpha) (\bar{\ell}_L^\gamma \gamma \ell_R^\alpha) + \left[ C_{ee}^{V,RR} \right]_{\alpha \beta \gamma \gamma} (\bar{\ell}_L^\gamma \gamma \ell_R^\alpha) (\bar{\ell}_L^\gamma \gamma \ell_R^\alpha) + \left[ C_{ee}^{V,LR} \right]_{\alpha \beta \gamma \gamma} (\bar{\ell}_L^\gamma \gamma \ell_R^\alpha) (\bar{\ell}_L^\gamma \gamma \ell_R^\alpha) \right). \tag{D.1}
\]

Using the expressions in [70,71], we find the following result for the branching ratio for \(\ell_\alpha \to \ell_\beta \ell_\gamma \ell_\gamma\):

\[
\frac{\mathcal{B}(\ell_\alpha \to \ell_\beta \ell_\gamma \ell_\gamma)}{\mathcal{B}(\ell_\beta \to \ell_\beta \nu_\beta \nu_\alpha)}_{SM} = \left( 2 \left[ \left| C_{ee}^{V,LL} \right|_{\alpha \beta \gamma \gamma} \right|^2 + 2 \left[ \left| C_{ee}^{V,RR} \right|_{\alpha \beta \gamma \gamma} \right|^2 + \left| \left[ C_{ee}^{V,LR} \right]_{\alpha \beta \gamma \gamma} \right|^2 \right) \right. \tag{D.2}
\]

\(\text{As suggested in 22, this option has the advantage of increasing the width of the TeV-scale vectors, hence alleviating the bounds from direct searches on these particles.}\)

\(\text{While } X_{q\ell} \neq 0 \text{ necessarily implies a breaking of } U(2)^5, \text{ more precisely a breaking of } U(2)_q \times U(2)_\ell, \text{ this is not the case for } X_{\ell \ell} \text{ and } X_{qq}; \text{ the latter break } U(2)^5 \text{ only if they are not proportional to the identity matrix.}\)
### Table C.2: Wilson coefficients of operators other than four-fermion ones.

| $[Q_{\nu\nu}]_{\alpha\beta\gamma\delta}$ | $[\Xi_{\nu\nu}]_{\alpha\beta\gamma\delta} = 18 \xi_{\alpha}\xi_{\beta}\xi_{\gamma}\xi_{\delta}$ |
Table C.4: Wilson coefficients of four-fermion operators. For the operators denoted with a [*], the hermitian conjugate has to be considered as well.
The presence of both left- and right-handed leptoquark couplings gives rise to contributions that amplitudes mediated by the leptoquark and the

On the other hand, we have that

\[ P(\tau \rightarrow \mu \gamma) \approx 0(1.7) \cdot 10^{-8} \]  

\[ B(\mu \rightarrow e\gamma) \approx 0(6) \cdot 10^{-14} \]  

Table D.1: List of observables involving LFV transitions.

| Purly leptonic LFV transitions | Experiment | EFT |
|-------------------------------|------------|-----|
| \[ \mathcal{B}(\tau \rightarrow 3\mu) \] | \(0(7) \cdot 10^{-9}\) | (D.2) |
| \[ \mathcal{B}(\mu \rightarrow 3e) \] | \(0(5) \cdot 10^{-13}\) | (D.2) |
| \[ \mathcal{B}(\tau \rightarrow \mu \gamma) \] | \(0(3) \cdot 10^{-8}\) | (D.3) |
| \[ \mathcal{B}(\mu \rightarrow e\gamma) \] | \(0(6) \cdot 10^{-14}\) | (D.3) |

| Semileptonic LFV transitions | Experiment | EFT |
|-------------------------------|------------|-----|
| \[ \mathcal{B}(B \rightarrow \tau^\pm e^\mp) \] | \(0.0(1.7) \cdot 10^{-5}\) | (D.7) |
| \[ \mathcal{B}(B \rightarrow \mu^\pm e^\mp) \] | \(0.0(1.5) \cdot 10^{-9}\) | (D.7) |
| \[ \mathcal{B}(K_L \rightarrow \mu^\pm e^\mp) \] | \(0.0(2.9) \cdot 10^{-12}\) | (D.7) |
| \[ \mathcal{B}(B^+ \rightarrow K^+\tau^+\mu^-) \] | \(0.0(1.7) \cdot 10^{-5}\) | (D.8) |

\[ \ell_\alpha \rightarrow \ell_\beta \gamma . \] In our model these processes receive the dominant contributions from one-loop amplitudes mediated by the leptoquark and the \(b\) quark. In spite of the loop suppression, the presence of both left- and right-handed leptoquark couplings gives rise to contributions that are \(m_b\)-enhanced. Considering only the enhanced contributions we find

\[
\begin{align*}
\mathcal{B}(\tau \rightarrow \mu \gamma) & \approx \frac{1}{\Gamma_\tau} \frac{\alpha m_\tau^2 m_\mu^2}{256 \pi^4 v^4} C_U^2 \sin^2 \tau, \\
\mathcal{B}(\mu \rightarrow e\gamma) & \approx \frac{1}{\Gamma_\mu} \frac{\alpha m_\mu^2 m_\mu^2}{256 \pi^4 v^4} C_U^2 \sin^2 \tau \sin^2 \theta_{\mu\tau}.
\end{align*}
\]

On the other hand, we have that \(\mathcal{B}(\tau \rightarrow e\gamma)\) is parametrically suppressed with respect to \(\mathcal{B}(\tau \rightarrow \mu \gamma)\) and thus does not give any relevant constraint.

\(P \rightarrow \ell \ell'\) and \(B \rightarrow K^{(*)} \tau \mu\). The leptoquark generally yields large contributions to leptonic and semileptonic LFV meson decays. To describe these processes it is useful to match the Wilson coefficients of the LEFT into the commonly used weak effective Hamiltonian

\[
\mathcal{H}_{WET} \supset -\frac{4G_F}{\sqrt{2}} \frac{e^2}{16\pi^2} v_\tau V_{ij}^* \sum_i \left\{ \mathcal{C}_i \mathcal{O}_i + h.c. \right\},
\]

where the operators are defined as

\[
\begin{align*}
\mathcal{O}^{ij,\alpha\beta}_9 & = (\bar{d}_j \gamma_\mu P_L d_i) (\bar{\tau}_\alpha \gamma_\mu e_\beta), \\
\mathcal{O}^{ij,\alpha\beta}_9 & = (\bar{d}_j \gamma_\mu P_R d_i) (\bar{\tau}_\alpha \gamma_\mu e_\beta), \\
\mathcal{O}^{ij,\alpha\beta}_{10} & = (\bar{d}_j \gamma_\mu P_L d_i) (\bar{\tau}_\alpha \gamma^\mu \gamma_5 e_\beta), \\
\mathcal{O}^{ij,\alpha\beta}_{10} & = (\bar{d}_j \gamma_\mu P_R d_i) (\bar{\tau}_\alpha \gamma^\mu \gamma_5 e_\beta), \\
\mathcal{O}^{ij,\alpha\beta}_S & = (\bar{d}_j P_L d_i) (\bar{e}_\alpha e_\beta), \\
\mathcal{O}^{ij,\alpha\beta}_S & = (\bar{d}_j P_R d_i) (\bar{e}_\alpha e_\beta), \\
\mathcal{O}^{ij,\alpha\beta}_P & = (\bar{d}_j P_R d_i) (\bar{e}_\alpha \gamma_5 e_\beta), \\
\mathcal{O}^{ij,\alpha\beta}_P & = (\bar{d}_j P_L d_i) (\bar{e}_\alpha \gamma_5 e_\beta), \\
\mathcal{O}^{ij,\alpha\beta}_\nu & = (\bar{d}_j \gamma_\mu P_L d_i) (\bar{\nu}_\alpha \gamma^\mu(1 - \gamma_5) \nu_\beta), \\
\mathcal{O}^{ij,\alpha\beta}_\nu & = (\bar{d}_j \gamma_\mu P_R d_i) (\bar{\nu}_\alpha \gamma^\mu(1 - \gamma_5) \nu_\beta).
\end{align*}
\]
with $P_{L,R} = 1/2(1 \mp \gamma_5)$. We have

$$C_{ij,\alpha\beta}^q = -\frac{2\pi}{\alpha V_{ij}^*} \left( [C_{ed}^{V,LL}]_{ij\alpha\beta} + [C_{de}^{V,LR}]_{ji\alpha\beta} \right) + C_{9ij,\alpha\beta}^S ,$$

$$C_{ij,\alpha\beta}^{10} = \frac{2\pi}{\alpha V_{ij}^*} \left( [C_{ed}^{V,LL}]_{ij\alpha\beta} - [C_{de}^{V,LR}]_{ji\alpha\beta} \right) + C_{10ij,\alpha\beta}^{SM} ,$$

$$C_{ij,\alpha\beta}^g = -\frac{2\pi}{\alpha V_{ij}^*} [C_{ed}^{S,RL}]_{ij\alpha\beta} ,$$

$$C_{ij,\alpha\beta}^P = -\frac{2\pi}{\alpha V_{ij}^*} [C_{ed}^{S,LL}]_{ij\alpha\beta} ,$$

$$C_{ij,\alpha\beta}^{10} = -\frac{2\pi}{\alpha V_{ij}^*} [C_{ed}^{V,RR}]_{ij\alpha\beta} + C_{10ij,\alpha\beta}^{SM} ,$$

$$C_{ij,\alpha\beta} = -\frac{2\pi}{\alpha V_{ij}^*} [C_{ed}^{V,LR}]_{ij\alpha\beta} ,$$

$$C_{ij,\alpha\beta}^{10} = -\frac{2\pi}{\alpha V_{ij}^*} [C_{ed}^{V,LR}]_{ij\alpha\beta} ,$$

$$(D.6)$$

with the SMEFT Wilson coefficients evaluated at the low-energy scale. Throughout the paper we will omit the quark indices whenever they refer to $b \to s$ transitions, i.e. when $ij = bs$. Using this effective Hamiltonian, we can write the branching fraction for the LFV leptonic decay of a neutral pseudo-scalar meson with valence quarks $i$ and $j$, $P_{ij}$, as

$$B(P_{ij} \to \ell_\alpha^{\pm} \ell_\beta^{\pm}) = 2 B(P_{ij} \to \ell_\alpha^{-} \ell_\beta^{+}) = \frac{\tau_{P}}{32\pi^{3}} \frac{G^{2}}{m_{P}^{3}} \frac{f_{P}^{2}}{F_{V_{ij}}^{*}} \left| V_{ij} \right|^{2} \lambda^{1/2}(m_{\mu}^{2}, m_{\tau}^{2}, m_{\ell_{\alpha}}^{2})$$

$$\times \left\{ \left[ m_{P}^{2} - (m_{\ell_{\alpha}} - m_{\ell_{\beta}})^{2} \right] \left( m_{\ell_{\alpha}} + m_{\ell_{\beta}} \right) \left( C_{ij,\alpha\beta}^{10} - C_{ij,\alpha\beta}^{10} \right) + \frac{m_{P}^{2}}{m_{i} + m_{j}} \left( C_{ij,\alpha\beta}^{10} - C_{ij,\alpha\beta}^{10} \right) \right\}^{2}$$

$$\times \left\{ \left[ m_{P}^{2} - (m_{\ell_{\alpha}} - m_{\ell_{\beta}})^{2} \right] \left( m_{\ell_{\alpha}} + m_{\ell_{\beta}} \right) \left( C_{ij,\alpha\beta}^{10} - C_{ij,\alpha\beta}^{10} \right) + \frac{m_{P}^{2}}{m_{i} + m_{j}} \left( C_{ij,\alpha\beta}^{10} - C_{ij,\alpha\beta}^{10} \right) \right\}^{2} ,$$

$$(D.7)$$

where the $P$ decay constant is defined as $\langle 0 | \bar{q}_{i} \gamma_{\mu} \gamma_{5} q_{j} | P(p) \rangle = i\tau_{P} f_{P}$. For the branching fraction of the LFV semileptonic decay $B \to K^{(*)} \tau \mu$ we have:

$$B(B \to K^{(*)} \tau^{+} \mu^{-}) = 10^{-9} \left( C_{K^{(*)}}^{9} |C_{9}^{\tau^{+}} + C_{9}^{\tau^{-}}|^{2} + C_{K^{(*)}}^{10} |C_{10}^{\tau^{+}} + C_{10}^{\tau^{-}}|^{2} + C_{K^{(*)}}^{9/2} |C_{9/2}^{\tau^{+}} - C_{9/2}^{\tau^{-}}|^{2} \right)$$

$$+ C_{K^{(*)}}^{10/2} |C_{10/2}^{\tau^{+}} - C_{10/2}^{\tau^{-}}|^{2} + C_{K^{(*)}}^{S} |C_{S}^{\tau^{+}} + C_{S}^{\tau^{-}}|^{2} + C_{K^{(*)}}^{P} |C_{P}^{\tau^{+}} + C_{P}^{\tau^{-}}|^{2}$$

$$+ \alpha_{K^{(*)}}^{S} \text{Re}[C_{S}^{\tau^{+}}|C_{S}^{\tau^{-}}|^{2} + C_{S}^{\tau^{-}}|C_{S}^{\tau^{+}}|^{2} + C_{K^{(*)}}^{P} |C_{P}^{\tau^{+}} + C_{P}^{\tau^{-}}|^{2} \left( C_{10}^{\tau^{+}} - C_{10}^{\tau^{-}} \right)\right] .$$

$$(D.8)$$

The $a_{K^{(*)}}^{j}$ coefficients are given Table D.2. They have been computed using the lattice inputs in [74], and have been cross checked against [75] for those involving the $C_{9(10)}$ operators only.
D.2 LFU tests in charged lepton decays and at LEP

Strong tests of LFU can be derived from the precise measurements of purely leptonic and semi-hadronic \( \tau \) decays. Here we use the results from the HFLAV [47]

**Leptonic decays.** Stringent tests of LFU can be obtained from ratios of leptonic lepton decays such as

\[
\left( \frac{g_{\tau}}{g_{\mu}} \right)_{\ell} = \left[ \frac{B(\tau \to e \nu \overline{\nu})_{\text{exp}}}{B(\tau \to e \nu \overline{\nu})_{\text{SM}}} \right]^{\frac{1}{2}},
\]

and analogously for the other leptons. These ratios can be written in terms of the effective Lagrangian:

\[
\mathcal{L}(\ell \to \ell' \nu \overline{\nu}) = - \frac{4G_F}{\sqrt{2}} \left[ \left( C_{\nu e, LL}^{V} \right)_{\rho \sigma \alpha \beta} (\overline{\nu}_L^\rho \gamma^\mu \nu_L^{\sigma}) (\overline{\tau}_L^\alpha \gamma^\mu \ell_L^{\beta}) + \left( C_{\nu e, LR}^{V} \right)_{\rho \sigma \alpha \beta} (\overline{\nu}_L^\rho \gamma^\mu \nu_L^{\sigma}) (\overline{\tau}_R^\alpha \gamma^\mu \ell_R^{\beta}) \right],
\]

yielding the following expressions:

\[
\left( \frac{g_{\tau}}{g_{\mu}} \right)_{\ell} = \frac{\sum_{\rho \sigma} \left( |\delta_{\rho3}\delta_{\sigma1}| + |C_{\nu e, LL}^{V(\sigma1)}| \right)^2}{\sum_{\rho \sigma} \left( |\delta_{\rho2}\delta_{\sigma1}| + |C_{\nu e, LL}^{V(\sigma1)}| \right)^2}^{\frac{1}{2}},
\]

\[
\left( \frac{g_{\tau}}{g_{\mu}} \right)_{\ell} = \frac{\sum_{\rho \sigma} \left( |\delta_{\rho3}\delta_{\sigma2}| + |C_{\nu e, LL}^{V(\sigma2)}| \right)^2}{\sum_{\rho \sigma} \left( |\delta_{\rho2}\delta_{\sigma1}| + |C_{\nu e, LL}^{V(\sigma1)}| \right)^2}^{\frac{1}{2}},
\]

\[
\left( \frac{g_{\mu}}{g_{e}} \right)_{\ell} = \frac{\sum_{\rho \sigma} \left( |\delta_{\rho3}\delta_{\sigma3}| + |C_{\nu e, LL}^{V(\sigma3)}| \right)^2}{\sum_{\rho \sigma} \left( |\delta_{\rho3}\delta_{\sigma1}| + |C_{\nu e, LL}^{V(\sigma1)}| \right)^2}^{\frac{1}{2}}.
\]

**Hadronic decays.** LFU violation in hadronic \( \tau \) decays can be tested by ratios such as

\[
\left( \frac{g_{\tau}}{g_{\mu}} \right)_{h} = \left[ \frac{B(\tau \to h \nu)}{B(h \to \mu \overline{\nu}) (1 + \delta R_{\tau/h}) m_{\tau}^2 \frac{2m_{\mu}m_{\tau}}{m_{h}^2}} \right]^{\frac{1}{2}}.
\]

The decay \( \tau^- \to h^- \nu \), with \( h^- = d_i \overline{\nu}_j \), is described by the Lagrangian

\[
\mathcal{L}(\tau \to h \nu) = - \frac{4G_F}{\sqrt{2}} \sum_{\rho} \left( \delta_{\rho3} V_{ji}^* + \left[ C_{\nu e u d}^{V} \right]_{\rho3ij} \right) (\overline{\nu}_L^\rho \gamma^\mu \tau_L) (\overline{d}_R^{i \gamma^\mu} u_L^j) + \left[ C_{\nu e u d}^{SRL} \right]_{\rho3ij} (\overline{\nu}_L^\rho \tau_R) (\overline{d}_R^{i \gamma^\mu} u_L^j),
\]

Note that for the \( K^* \) channel the scalar contributions are expected to be negligible and hence we do not provide them.
where we included also the SM contribution. The branching ratio for the process reads
\[ \mathcal{B}(\tau \to h\nu) = \frac{1}{16\pi^2} G_F^2 f_h^2 m_\tau^2 \left( 1 - \frac{m_h^2}{m_\tau^2} \right)^2 \left| \delta_{33} V_{ij}^* + \left[ \mathcal{C}_{\nu\nu\nu}^{V,LL} \right]_{\rho3ij} + \frac{m_h^2}{m_\tau(m_d + m_u)} \left[ \mathcal{C}_{\nu\nu\nu}^{S,RL} \right]_{\rho3ij} \right|^2, \]
and analogously for \( \mathcal{B}(h \to \mu\nu) \). Thus we find the following theoretical predictions for \((g_\tau/g_\mu)_\pi\) and \((g_\tau/g_\mu)_K\)
\[ \left( \frac{g_\tau}{g_\mu} \right)_\pi = \left( \frac{\sum_\rho \delta_{33} V_{ui}^* + \left[ \mathcal{C}_{\nu\nu\nu}^{V,LL} \right]_{\rho311} + \frac{m_h^2}{m_\tau(m_d + m_u)} \left[ \mathcal{C}_{\nu\nu\nu}^{S,RL} \right]_{\rho311} \right)^{\frac{1}{2}}, \]
\[ \left( \frac{g_\tau}{g_\mu} \right)_K = \left( \frac{\sum_\rho \delta_{33} V_{ui}^* + \left[ \mathcal{C}_{\nu\nu\nu}^{V,LL} \right]_{\rho321} + \frac{m_h^2}{m_\tau(m_d + m_u)} \left[ \mathcal{C}_{\nu\nu\nu}^{S,RL} \right]_{\rho321} \right)^{\frac{1}{2}}, \]

Due to the flavor structure of the model, tree-level leptoquark contributions in the hadronic \( \tau \) vs \( \mu \) ratios are found to be much smaller than those induced by the \( m_d \)-enhanced leptoquark loop. As a consequence, we find \((g_\tau/g_\mu)_\pi \approx (g_\tau/g_\mu)_K \approx (g_\tau/g_\mu)_K\) to a good extent. Similar tests with hadronic \( \tau \) vs \( \epsilon \) ratios can also be performed. These are less precise and do not yield relevant constraints.

We also use the results of the fit in [76] to account for the bounds on precision \( Z \)- and \( W \)-pole measurements at LEP. The experimental measurements we use in the fit for the LFU tests described in this section are summarized in Table D.3.

### D.3 \( \Delta F = 1 \) semi-leptonic processes

**b \to s** transitions. We describe the NP contributions to \( b \to s\ell\bar{\ell} \) and \( b \to s\nu\bar{\nu} \) transitions in terms of the effective operators in (D.5). The model predicts \( \text{Re} \left( C_9^{\alpha\alpha} \right) \approx - \text{Re} \left( C_{10}^{\alpha\alpha} \right) \) to a
very good approximation so we use fit results in [51] (see also [52,53]) for this NP hypothesis. In order to analyse possible departures given by the scalar operators we also consider the $B_q \to \ell\ell$ ($q = s,d$) channels separately. We have

$$
B(B_q \to \ell^-\ell^+) = \mathcal{B} \left( B_q \to \ell^-\ell^+ \right) \left|_{SM} \right. \left\{ \left| \frac{C^{bq,\ell\ell}}{C^{10}_{SM}} \right|^2 + m_{B_q}^2 \frac{C^{bq,\ell\ell}}{C^{10}_{SM}} \right\}
+ \frac{m_{B_q}^2 - 4m_\ell^2}{m_{B_q}^2} \left[ \frac{C^{bq,\ell\ell}}{C^{10}_{SM}} \right]^2 \right\},
$$
(D.16)

with the experimental and SM values listed in Table D.4. The branching fraction of the $B \to K^{(*)}\nu\bar{\nu}$ decays are given by

$$
\mathrm{B}(B \to K^{(*)}\nu\bar{\nu}) \left|_{SM} \right. = \frac{\sum_{\alpha,\beta} |C_\alpha^\nu + C_\nu^\beta|^2}{3|C_\nu^{SM}|^2},
$$
(D.17)

with the SM Wilson coefficient $C_\nu^{SM} \approx -6.35$ [77,78].

$s \to d$ transitions. Here we focus only in $s \to d\nu\bar{\nu}$ decays. Since right-handed rotations involving the light families are negligible, the NP Lagrangian relevant for the $s \to d\nu\bar{\nu}$ transition reads

$$
\mathcal{L}(s \to d\nu\bar{\nu}) = \frac{-4G_F}{\sqrt{2}} \left[ C_{ed}^{V,LL} \right]_{\alpha\beta 21} (\bar{\nu}_L^\beta \gamma^\mu \nu_L^\alpha)(\bar{s}_L \gamma_\mu d_L).
$$

(D.18)

Constraints on the Wilson coefficients above can be obtained from the measurements of $\mathcal{B}(K^+ \to \pi^+\nu\bar{\nu})$ and $\mathcal{B}(K_L \to \pi^0\nu\bar{\nu})$, whose experimental values (with symmetrized errors) and SM predictions are collected in Table D.4. The NP predictions in terms of the EFT (assuming NP only in $\nu_\tau$) can be extracted from [79] and read

$$
\mathcal{B}(K^+ \to \pi^+\nu\bar{\nu}) = \mathcal{B}(K^+ \to \pi^+\nu\bar{\nu}) \left|_{SM} \right. \left\{ \frac{2}{3} + \frac{1}{3} \right\} \left| \frac{2 \left[ C_{ed}^{V,LL} \right]_{3321}}{(\alpha/\pi) V_{ts}^* V_{td} C_{ed,\tau}^{SM,\text{eff}} \left( G_F^2 \right)} \right|^2
$$

(D.19)

$$
\mathcal{B}(K_L \to \pi^0\nu\bar{\nu}) = \mathcal{B}(K_L \to \pi^0\nu\bar{\nu}) \left|_{SM} \right. \left\{ \frac{2}{3} + \frac{1}{3} \right\} \left| \frac{2 \left[ C_{ed}^{V,LL} \right]_{3321}}{(\alpha/\pi) V_{ts}^* V_{td} (X_t/s_W^2 \left( G_F^2 \right)} \right|^2
$$

where $C_{ed,\tau}^{SM,\text{eff}} \approx -8.5 e^{0.11i}$ (including the long-distance contributions), and $X_t/s_W^2 \approx 6.4$. Given that the bounds from $K_L$ decays are way less stringent than those from the $K^+$, we implement only the latter in the fit.

$b \to c (u)$ transitions. In our setup, these transitions are described by the following effective operators:

$$
\mathcal{L}(b \to u_\ell\bar{\nu}) = \frac{-4G_F}{\sqrt{2}} \left[ C_{udedu}^{V,LL} \right]_{\alpha\beta 3k} (\bar{\nu}_L^\beta \gamma^\mu \nu_L^\alpha)(\bar{u}_L \gamma_\mu b_L) + \left[ C_{udedu}^{S,RL} \right]_{\alpha\beta 3k} (\bar{\nu}_L^\beta \nu_L^\alpha)(\bar{u}_L b_R),
$$

(D.20)
where \( i = 1, 2 \) for a \( u \) or a \( c \) quark respectively. We define the LFU ratios \( R_{D^{(*)}}^{\ell\ell} \) as

\[
R_{D^{(*)}}^{\ell\ell} = \frac{B(B \to D^{(*)}(\nu) \to \ell\nu)}{B(B \to D^{(*)}\ell\nu)},
\]

for which we find the following expression in terms of the EFT Wilson coefficients

\[
R_{D^{(*)}}^{\ell\alpha\beta} = R_{D^{(*)}}^{\ell\alpha\beta}|_{\text{SM}} \left[ 1 + 2 \text{Re} \left\{ \frac{[C_{\nu\nu\alpha\beta}^{V,LL}]^*}{V_{cb}} \right\} + f_D^S(\ell) \text{Re} \left\{ \frac{[C_{\nu\nu\alpha\beta}^{S,RL}]^*}{V_{cb}} \right\} - (\alpha \to \beta) \right],
\]

The hadronic information on the scalar contributions is encoded in \( f_D^S(\ell) \). In our model, scalar contributions with taus are sizeable while those involving light leptons are negligible. For the tau channel we have \( 48 \)

\[
f_D^S(\tau) = 0.12 , \quad f_D^S(\tau) = 1.5.
\]

In order to constrain \( e - \mu \) universality in \( B \to D\nu \) and \( B \to D^*\ell\nu \) we use the \( V_{cb} \) determinations in \( 86 \) instead of \( R_{D^{(*)}}^{\ell\ell} \). The former also include the information on the differential distributions and therefore lead to stronger constraints than the ones on the branching ratios alone. We construct the following universality ratios, analogous to \( R_{D^{(*)}}^{\ell\ell} \),

\[
V_{D^{(*)}}^{\mu e} = \frac{V_{cb}^{B\to D^{(*)}\mu\nu}}{V_{cb}^{B\to D^{(*)}\ell\nu}}.
\]

Since we expect scalar contributions involving light leptons to be suppressed, we find

\[
V_{D}^{\mu e} = V_{D^{(*)}}^{\mu e} \approx 1 + 2 \text{Re} \left\{ \frac{C_{\nu\nu\alpha\beta}^{V,LL}}{V_{cb}} \right\} - 2 \text{Re} \left\{ \frac{C_{\nu\nu\alpha\beta}^{S,RL}}{V_{cb}} \right\}.
\]

Finally, defining the ratio of inclusive \( B \) decays into charm states as

\[
R_{X_c}^{\ell\ell} = \frac{B(B \to X_c \tau\nu)}{B(B \to X_c\ell\nu)},
\]

and neglecting the light-lepton scalar contribution, we have

\[
R_{X_c}^{\ell\ell} = R_{X_c}^{\ell\ell}|_{\text{SM}} \left[ 1 + 2 \text{Re} \left\{ \frac{[C_{\nu\nu\alpha\beta}^{V,LL}]}{V_{cb}} \right\} + 0.427 \text{Re} \left\{ \frac{[C_{\nu\nu\alpha\beta}^{S,RL}]}{V_{cb}} \right\} - 2 \text{Re} \left\{ \frac{[C_{\nu\nu\alpha\beta}^{S,RL}]}{V_{cb}} \right\} \right],
\]

with \( R_{X_c}^{\ell\ell}|_{\text{SM}} = 0.212 \pm 0.003 \) and where we used the results in \( 80 \) for the scalar contributions.

The only important constraint in \( b \to u\ell\nu \) transitions is given by the \( B \to \tau \bar{\nu}_\tau \) branching fraction. For \( B_q \to \tau \bar{\nu}_\tau \) (\( q = u, c \)), we have

\[
B(B_q \to \tau \bar{\nu}) = B(B_q \to \tau \bar{\nu}_\tau)|_{\text{SM}} \sum_\rho \delta_{\rho3} + \frac{[C_{\nu\nu\rho3q}^{V,LL}]}{V_{qb}} + \frac{m_{B_q}^2}{(m_b + m_q)m_\tau} \frac{[C_{\nu\nu\rho3q}^{S,RL}]}{V_{qb}}^2.
\]

In the fit we use \( B(B \to \tau \bar{\nu}_\tau)|_{\text{SM}} = 0.807(61) \) \( 45 \) for the SM value.
weak phases of non-leptonic

A relevant constraint is obtained by time-dependent CP-violating asymmetries probing the weak phases of non-leptonic $b \rightarrow s$ amplitudes. The relevant effective Lagrangian reads

$$\mathcal{L}_{\Delta F=2}^{(b \rightarrow s L)} = -\frac{4G_F}{\sqrt{2}} \sum_a c_a O_a = -\frac{4G_F}{\sqrt{2}} \left[ [\mathcal{C}^{V,LL}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{d}_L \gamma^\mu d_L) \\
+ [\mathcal{C}^{V,LL}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{u}_L \gamma^\mu u_L) + [\mathcal{C}^{V,LR}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{d}_R \gamma^\mu d_R) + [\mathcal{C}^{V,LR}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{u}_R \gamma^\mu u_R) + [\mathcal{C}^{V,LR}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{d}_R \gamma^\mu d_R) \\
+ [\mathcal{C}^{V,LR}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{u}_R \gamma^\mu u_R) + [\mathcal{C}^{V,LR}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{d}_R \gamma^\mu d_R) \right].$$

Table D.4: List of observables involving semileptonic transitions.

**D.4 $\Delta F = 1$ non-leptonic processes**

A relevant constraint is obtained by time-dependent CP-violating asymmetries probing the weak phases of non-leptonic $b \rightarrow s$ amplitudes. The relevant effective Lagrangian reads

$$\mathcal{L}_{\Delta F=2}^{(b \rightarrow s L)} = -\frac{4G_F}{\sqrt{2}} \sum_a c_a O_a = -\frac{4G_F}{\sqrt{2}} \left[ [\mathcal{C}^{V,LL}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{d}_L \gamma^\mu d_L) \\
+ [\mathcal{C}^{V,LL}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{u}_L \gamma^\mu u_L) + [\mathcal{C}^{V,LR}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{d}_R \gamma^\mu d_R) + [\mathcal{C}^{V,LR}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{u}_R \gamma^\mu u_R) + [\mathcal{C}^{V,LR}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{d}_R \gamma^\mu d_R) \\
+ [\mathcal{C}^{V,LR}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{u}_R \gamma^\mu u_R) + [\mathcal{C}^{V,LR}]_{b s i} (\bar{b}_L \gamma^\mu s_L)(\bar{d}_R \gamma^\mu d_R) \right].$$

38
For a given exclusive transition of the type $B_{s,d} \to F$ we can write

$$\mathcal{A}(B_q \to F) \approx \mathcal{A}(B_q \to F)_{\text{SME}} e^{i\Delta\phi_q^{[F]}}, \quad \Delta\phi_q^{[F]} = \sum_{a} (b_q^{[F]})_{c_a} \times \text{Im} \left[ \frac{C_a}{V_{ts} V_{tb^*}} \right], \quad (D.30)$$

where the $(b_q^{[F]})_{c_a}$ are real parameters encoding the RG evolution from the week scale down to $m_b$ and the hadron matrix elements of various four-quark operators.

The phase shift $\Delta\phi_q^{[F]}$ is directly constrained by the CP-violating asymmetries. In particular, in the clean case of $B_d \to \psi K$ one finds

$$\left| \Delta\phi_d^{[\phi K]} \right|_{\exp} = \left| \frac{\sin(2\beta)_{\phi K} - \sin(2\beta)_{\psi K}}{\sin(2\beta)_{\psi K}} \right| = 0.07 \pm 0.15. \quad (D.31)$$

Following the analysis of Ref. [92], in this case the dominant non-vanishing coefficients are

$$(b_q^{[\phi K]})_{[c_{dd}^{V,LL}]} \approx (b_q^{[\phi K]})_{[c_{dd}^{V,LR}]} \approx -45, \quad (b_q^{[\phi K]})_{[c_{dd}^{V,LL}]} \approx -4. \quad (D.32)$$

### D.5 $\Delta F = 2$ Transitions

The Lagrangian that contributes to $\Delta F = 2$ in the down sector is given by

$$\mathcal{L}_{\Delta F=2} = -\frac{4G_F}{\sqrt{2}} \left[ [C_{dd}^{V,LL}]_{ijij} (\bar{d}_L^i \gamma^\mu d_L^i)(\bar{d}_R^i \gamma^\mu d_R^i) + [C_{dd}^{V,RR}]_{ijij} (\bar{d}_L^i \gamma^\mu d_R^i)(\bar{d}_R^i \gamma^\mu d_L^i) \right. \right.$$  

$$\left. + [C_{dd}^{V,LR}]_{ijij} (\bar{d}_L^i \gamma^\mu d_L^i)(\bar{d}_R^i \gamma^\mu d_R^i) + [C_{dd}^{V,LR}]_{ijij} (\bar{d}_L^i \gamma^\mu d_L^i)(\bar{d}_R^i \gamma^\mu T^a d_R^i) \right], \quad (D.33)$$

where $T^a$ are the generators of $SU(3)_c$. In order to study neutral meson mixing it is convenient to reexpress this operators in terms of the basis used in [93]. After fierzing the operator $O_{dd}^{V,LR}$ we find

$$\mathcal{L}_{\Delta F=2} = -\frac{4G_F}{\sqrt{2}} \left[ [C_{dd}^{V,LL}]_{ijij} [Q_1^{V LL}]_{ijij} + [C_{dd}^{V,RR}]_{ijij} [Q_1^{V RR}]_{ijij} \right. \right.$$  

$$\left. + \left( [C_{dd}^{V,LR}]_{ijij} - \frac{1}{6} [C_{dd}^{V,LR}]_{ijij} \right) [Q_1^{V LR}]_{ijij} - [C_{dd}^{V,LR}]_{ijij} [Q_2^{LR}]_{ijij} \right]. \quad (D.34)$$

**$B_{s,d} - \bar{B}_{s,d}$ mixing.** The hadronic matrix elements for the operators relevant to $B_q - \bar{B}_q$ mixing ($q = d, s$) are conventionally decomposed as follows

$$\langle \bar{B}_q^0 | Q_1^{V LL}(\mu) | B_q^0 \rangle = \frac{1}{3} m_{B_q} f_{B_q}^2 B_q^{V LL}(\mu),$$

$$\langle B_q^0 | Q_1^{V LR}(\mu) | B_q^0 \rangle = -\frac{1}{6} R_q^1(\mu) m_{B_q} f_{B_q}^2 B_q^{V LR}(\mu), \quad (D.35)$$

$$\langle \bar{B}_q^0 | Q_2^{LR}(\mu) | B_q^0 \rangle = \frac{1}{4} R_q^2(\mu) m_{B_q} f_{B_q}^2 B_q^{LR 2}(\mu).$$

Here the so-called bag parameters $B_q^a(\mu)$, which are expected to be one in the vacuum saturation approximation, can be calculated in lattice QCD. The latest lattice determinations can be found
Table D.5: Bag parameters taken from [42] [Fermilab/MILC Collaboration, 2016] and adjusted to Buras et al. operator basis.

|                  | (MS–BMU, $m_b$) |
|------------------|------------------|
| $B_{d}^{LR1}/B_{d}^{VLL}$ | 1.06(11)         |
| $B_{d}^{LR2}/B_{d}^{VLL}$ | 1.14(10)         |
| $B_{s}^{LR1}/B_{s}^{VLL}$ | 0.990(75)        |
| $B_{s}^{LR2}/B_{s}^{VLL}$ | 1.073(68)        |

Table D.5: Bag parameters taken from [42] [Fermilab/MILC Collaboration, 2016] and adjusted to Buras et al. operator basis.

The chirality factors $R_i(\mu)$ are defined as

$$R_i(\mu) = \left[ \frac{m_{B_i}}{m_b(\mu) + m_q(\mu)} \right]^2 + \frac{3}{2}, \quad R_q(\mu) = \left[ \frac{m_{B_q}}{m_b(\mu) + m_q(\mu)} \right]^2 + \frac{1}{6},$$

with $\mu$ denoting the low-energy scale.

In the SM only the operator $Q_1^{VLL}(\mu)$ contributes to the $\mathcal{M}(B_q \rightarrow \bar{B}_q) \equiv \mathcal{M}_{12}(B_q)$ amplitude. We normalize it such that the meson-antimeson mass splitting and the CP-violating phase of mixing amplitude are defined by

$$\Delta M_q = 2|\mathcal{M}_{12}(B_q)|, \quad \phi_{B_q} = \text{arg} [\mathcal{M}_{12}(B_q)].$$

The explicit expression in the SM reads

$$\mathcal{M}_{12}(B_q)^{\text{SM}} = \frac{G_F^2 M_W^2 M_{B_q}}{12\pi^2} S_0(x_t)(V_{tq} V_{ts}^*)^2 f_{B_q}^2 \hat{\eta}_B B_q^{VLL},$$

with $S_0(x_t) \approx 2.36853$ being the Inami-Lim function [95], and $\hat{\eta}_B \approx 0.842$ [93] accounting for the QCD running of the effective operator from the $m_t$ to the $m_b$ scale. In the presence of NP, the expression of $\mathcal{M}_{12}(B_q)$ is modified; factorizing the SM contribution, we can generally decompose it as

$$\mathcal{M}_{12}(B_q) = \mathcal{M}_{12}(B_q)^{\text{SM}} \left[ 1 + \frac{\mathcal{M}_{12}(B_q)^{\text{NP}}}{\mathcal{M}_{12}(B_q)^{\text{SM}}} \right].$$

The NP modifications can be written in terms of the Wilson coefficients in (D.33) as follows

$$\frac{\mathcal{M}_{12}(B_q)^{\text{NP}}}{\mathcal{M}_{12}(B_q)^{\text{SM}}} = \frac{1}{(V_{tq} V_{ts}^*)^2 P_{\text{SM}}^{\text{loop}}} \left[ \left[ \mathcal{C}_{dd}^{\text{VLL}}(\mu_t) \right]_{3q3q} + \left[ \mathcal{C}_{dd}^{\text{RR}}(\mu_t) \right]_{3q3q} \right]$$

$$+ \frac{P_{q}^{LR1}(\mu_b)}{P_{q}^{VLL}(\mu_b)} \left[ \mathcal{C}_{dd}^{\text{VIR}}(\mu_t) \right]_{3q3q} - \frac{1}{6} \left[ \mathcal{C}_{dd}^{\text{VIR}}(\mu_t) \right]_{3q3q},$$

where the SM factor reads

$$R_{\text{SM}}^{\text{loop}} = \frac{\sqrt{2} G_F M_W^2 S_0(x_t)}{16\pi^2} = 1.5987 \times 10^{-3},$$

We stress that even though [42] and [93] adopt different conventions for the definition of the hadronic matrix elements, the matching between the different definitions of bag factors is consistent and unambiguous. In particular, the bag factors in Table D.5 have a one to one matching with the ones used in Eqs. (7.28)-(7.30) of [93].

12 We stress that even though [42] and [93] adopt different conventions for the definition of the hadronic matrix elements, the matching between the different definitions of bag factors is consistent and unambiguous. In particular, the bag factors in Table D.5 have a one to one matching with the ones used in Eqs. (7.28)-(7.30) of [93].
Using the results in Table D.5 for the bag factors we find bag factors. These are given by
\[ P_m \] and Eq. (7.34) \[ (D.34) \] with \[ \alpha_i = \frac{e_i}{\mu} \] to impose the weaker constraint on the bag parameter. As far as the magnitude of the amplitude is concerned, we can limit ourselves to the simple form
\[ |\epsilon|^\text{NP} = |\epsilon|^\text{SM} + \frac{2}{3} C_K P_1^{VLL}(\mu_K) \text{Im} \left[ [C_{dd}^{VLL}]_{2121}(\mu_t) \right] , \] (D.45)
where we have used \( \text{Re}(\epsilon_K) = |\epsilon_K|/\sqrt{2} \), we have defined
\[ C_K = \frac{G_F M_K f_K^2}{M_K^{\exp}} = 4.23 \times 10^7 , \] (D.46)
and we have introduced the factor \( P_1^{VLL}(\mu_K) = 0.48 \) (D.47) that encodes QCD corrections and the bag parameter. As far as the magnitude of the amplitude is concerned, we can limit ourselves to impose the weaker constraint
\[ \frac{\Delta M_K^{\exp}}{\Delta M_K^{\text{NP}}} = \frac{8}{3 \sqrt{2}} C_K P_1^{VLL}(\mu_K) \left| [C_{dd}^{VLL}]_{2121}(\mu_t) \right| < 1 . \] (D.47)

In the case of \( D - \bar{D} \) mixing we can also neglect right-handed rotations and corresponding right-handed operators. Following the analysis of Ref. \[ 44 \], the constraint following from the non-observation of CP-violation in this system can be expressed as
\[ \text{Im}(C_1^D) = \frac{4 G_F}{\sqrt{2}} \text{Im} \left[ [C_{uu}^{VLL}]_{2121}(\mu_t) \right] = (-0.03 \pm 0.46) \times 10^{-14} \text{ GeV}^{-2} . \] (D.48)

---

\[ 13 \] Here we use the results from \[ 93 \]. In particular, Tables 1 and 2 [with \( \alpha_i(M_Z) = 0.118 \), Eqs. (7.28)-(7.30) and Eq. (7.34) [with \( m_t(\mu_b) + m_d(\mu_b) = \mu_b = 4.4 \text{ GeV} \) and \( m_H = 5.28 \text{ GeV} \)].
\[ \Delta F = 2 \text{ transitions} \]

| Observable | Experiment | SM | LEFT |
|------------|------------|----|------|
| \( \Delta M_d \) | 0.5065(19) ps\(^{-1}\) | 47 | 0.630(69) ps\(^{-1}\) | 42 |
| \( \Delta M_s \) | 17.757(21) ps\(^{-1}\) | 47 | 19.6(1.6) ps\(^{-1}\) | 42 |
| \( \sin(\phi_{B_s}) \) | \(-0.021 \pm 0.031\) | 47 | \(-0.036 \pm 0.001\) | 45 |
| \( \sin(\phi_{B_d}) \) | \(-0.680 \pm 0.023\) | 47 | \(-0.724 \pm 0.028\) | 45 |
| \( 10^3 \times |\epsilon_K| \) | 2.228 \pm 0.011 | 47 | 2.03 \pm 0.18 | 45 |
| \( 10^{14} \times \text{Im}(C_1^D) \) | \(-0.03(46) \text{ GeV}^{-2}\) | 44 | 0. | D.45 |
| \( 10^{14} \times \text{Im}(C_1^D) \) | \(-0.03(46) \text{ GeV}^{-2}\) | 44 | 0. | D.48 |

Table D.6: List of observables involving hadronic transitions.
