(October 27, 2018)

The Drude weight for the one-dimensional Hubbard model is investigated at finite temperatures by using the Bethe ansatz solution. Evaluating finite-size corrections to the thermodynamic Bethe ansatz equations, we obtain the formula for the Drude weight as the response of the system to an external gauge potential. We perform low-temperature expansions of the Drude weight in the case of half-filling as well as away from half-filling, which clearly distinguish the Mott-insulating state from the metallic state.

I. INTRODUCTION

The Mott-Hubbard metal-insulator transition (MIT) is one of the long-standing important issues in strongly correlated electron systems. The one-dimensional (1D) Hubbard model is a fundamental model which describes the MIT. This model is exactly solvable in terms of the Bethe ansatz method. Various thermodynamic quantities such as the specific heat and the spin- and charge-susceptibilities which characterize the MIT have been obtained exactly. However, the study on transport properties such as the Drude weight based upon the Bethe ansatz method was restricted to the zero temperature case. The Drude weight at finite temperatures was investigated only by using numerical methods so far. Since the Drude weight is a direct probe for the MIT, it is desirable to obtain the finite-size corrections to the thermodynamic Bethe ansatz equations. For this purpose, we generalize standard methods for finite-size corrections based on the Euler-Maclaurin formula to the case of finite temperatures, and obtain the leading temperature dependence of the Drude weight at low temperatures.

II. FINITE-SIZE CORRECTIONS TO THE THERMODYNAMIC BETHE ANSATZ EQUATIONS

In this section we consider finite-size effects on the Bethe ansatz solutions of the 1D Hubbard model at finite temperatures. Finite-size effects at zero temperature have been studied by many authors in connection with the application of conformal field theory. We generalize their method to the case of finite temperatures. The hamiltonian of the 1D Hubbard model reads,

\[ H = -\sum_{\sigma \sigma'} c_{\sigma i}^\dagger c_{\sigma' i+1} + h.c. + U \sum_{i} c_{\uparrow i}^\dagger c_{\uparrow i} c_{\downarrow i}^\dagger c_{\downarrow i}. \]
It is necessary to introduce the Aharonov-Bohm (AB) flux $\Phi$ to formulate the Drude weight as the response to an external gauge potential. Alternatively, the effect of the AB flux is incorporated into the twisted boundary condition for the wave function, $\Psi(x + L) = e^{i\Phi}\Psi(x)$. The Bethe ansatz equations in the presence of the AB flux are given by

$$e^{ik_jL} = e^{i\Phi} \prod_{\alpha=1}^{M} \frac{\sin k_j - \Lambda_\alpha + iu}{\sin k_j - \Lambda_\alpha - iu},$$

$$\prod_{j=1}^{N} \frac{\Lambda_\alpha - \sin k_j + iu}{\Lambda_\alpha - \sin k_j - iu} = -\prod_{\beta=1}^{M} \frac{\Lambda_\alpha - \Lambda_\beta + 2iu}{\Lambda_\alpha - \Lambda_\beta - 2iu}. \quad (3)$$

Here $k_j$ and $\Lambda_\alpha$ are, respectively, the rapidities for the charge and spin degrees of freedom, and we have introduced $u = U/4$. $N$ and $M$ are the total number of electrons and down spins.

Thermodynamic Bethe ansatz solution for the 1D Hubbard model was obtained by Takahashi many years ago with the use of so-called string hypothesis. The validity of the string hypothesis is justified only for the thermodynamic limit $L \to \infty$. In order to calculate the Drude weight, we should evaluate the energy for a finite-size system, because the effect of $\Phi$ vanishes in the thermodynamic limit. Thus one may worry about whether the string hypothesis can be applied to the calculation of the Drude weight. However, by recalling the following fact we can still adopt the string hypothesis for our purpose: The corrections to the string hypothesis for a finite-size system is estimated as $\sim O(e^{-cL})$, where $c$ is a constant which depends on the temperature. On the other hand, the dependence of the energy on the AB flux appears in the order of $1/L^2$. Thus the correction to the string hypothesis for the finite-size system is much smaller than the finite-size corrections to the energy spectrum which we need for the calculation of the Drude weight. This situation is analogous to that for the Kondo model or the impurity Anderson model, where the local electron correlations, which are given by the $1/L$-corrections to bulk quantities, are correctly evaluated based upon the string hypothesis.

Using the string hypothesis, we can thus write down the thermodynamic Bethe ansatz equations. After taking the logarithm of the above equations, we end up with

$$k_jL = 2\pi I_j + \Phi - \sum_{n=1}^{\infty} \sum_{\alpha=1}^{M_n} \theta \left( \frac{\sin k_j - \Lambda^n_\alpha}{nu} \right)$$

$$- \sum_{n=1}^{\infty} \sum_{\alpha=1}^{M'_n} \theta \left( \frac{\sin k_j - \Lambda'^n_\alpha}{nu} \right), \quad (4)$$

$$L(\sin^{-1}(\Lambda'^n_\alpha + i nu) + \sin^{-1}(\Lambda'^n_\alpha - i nu)) = 2\pi J'^n_\alpha + 2n\Phi + \sum_{j=1}^{N-2M'} \theta \left( \frac{\sin k_j - \Lambda'^n_\alpha}{nu} \right) + \sum_{m=1}^{\infty} \sum_{\beta} \Theta_{nm} \left( \frac{\Lambda'^n_\alpha - \Lambda'^\beta_m}{u} \right), \quad (5)$$

$$\sum_{j=1}^{\infty} \theta \left( \frac{\sin k_j - \Lambda'^n_\alpha}{nu} \right) = 2\pi J'^n_\alpha + \sum_{m=1}^{\infty} \sum_{\beta} \Theta_{nm} \left( \frac{\Lambda'^n_\alpha - \Lambda'^\beta_m}{u} \right), \quad (6)$$

with $\theta(x) = 2\tan^{-1}x$ and

$$\Theta_{nm}(x) = \begin{cases} \theta \left( \frac{x}{n-m} \right) + 2\theta \left( \frac{x}{n-m+2} \right) + \cdots + 2\theta \left( \frac{x}{n+m-2} \right) + \theta \left( \frac{x}{n+m} \right) & n \neq m \\ 2\theta \left( \frac{x}{2} \right) + \cdots + 2\theta \left( \frac{x}{2n-2} \right) + \theta \left( \frac{x}{2n} \right) & n = m. \end{cases} \quad (7)$$

Here $k_j$ is the rapidity for charge excitations which are not in bound states, $\Lambda^n_\alpha$ is that for spin excitations, and $\Lambda'^n_\alpha$ is that for bound states. $I_j$, $J^n_\alpha$, and $J'^n_\alpha$ are the corresponding quantum numbers which specify the above excitations, respectively. $M_n$ is the number of $n$-strings for spin excitations. $2M'$ is the total number of electrons which make bound states.
In order to calculate the finite-size corrections to the energy spectrum, we expand the rapidities in terms of $1/L$ following Berkovich and Murthy

\[
\begin{align*}
k_j &= k_j^\infty + \frac{f_1}{L} + \frac{f_2}{L^2} + O(1/L^3), \\
\Lambda^n_\alpha &= \Lambda^n_{\alpha\infty} + \frac{g_1 n}{L} + \frac{g_2 n^2}{L^2} + O(1/L^3), \\
\Lambda'^n_\alpha &= \Lambda'^n_{\alpha\infty} + \frac{h_1 n}{L} + \frac{h_2 n^2}{L^2} + O(1/L^3).
\end{align*}
\]  

(8)

The lowest-order contributions in $1/L$ give the conventional thermodynamic Bethe ansatz equations which read,

\[
(1 + \zeta(k))\rho(k) = \frac{1}{2\pi} + \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} \frac{d\Lambda}{\pi} \frac{nu \cos k (\sigma_n(\Lambda) + \sigma'_n(\Lambda))}{(nu)^2 + (\sin k - \Lambda)^2},
\]

(9)

\[
\eta_n(\Lambda)\sigma_n(\Lambda) + \sum_{m=1}^{\infty} A_{nm} * \sigma_m(\Lambda) = \int_{-\infty}^{\infty} \frac{dk}{\pi} \frac{nu \rho(k)}{(nu)^2 + (\sin k - \Lambda)^2},
\]

(10)

\[
\eta'_n(\Lambda)\sigma'_n(\Lambda) + \sum_{m=1}^{\infty} A_{nm} * \sigma'_m(\Lambda) = \frac{1}{\pi} \Re \frac{1}{\sqrt{1 - (\Lambda - i nu)^2}} - \int_{-\infty}^{\infty} \frac{dk}{\pi} \frac{nu \rho(k)}{(nu)^2 + (\sin k - \Lambda)^2},
\]

(11)

\[
\ln(1 + \eta_n(\Lambda)) + \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{nu \cos k}{(nu)^2 + (\sin k - \Lambda)^2} \ln(1 + \zeta^{-1}(k)) = \frac{2n\mu_0 H}{T} + \sum_{m=1}^{\infty} A_{nm} * \ln(1 + \eta^{-1}_m(\Lambda)),
\]

(13)

\[
\ln(1 + \eta'_n(\Lambda)) + \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{nu \cos k}{(nu)^2 + (\sin k - \Lambda)^2} \ln(1 + \zeta^{-1}(k)) = \frac{4\Re \sqrt{1 - (\Lambda - i nu)^2} - 2nA}{T} + \sum_{m=1}^{\infty} A_{nm} * \ln(1 + \eta'^{-1}_m(\Lambda)),
\]

(14)

where

\[
\rho(k), \sigma_n(\Lambda), \text{ and } \sigma'_n(\Lambda) \text{ are the distribution functions for the rapidities, } k_j, \Lambda^n_\alpha, \text{ and } \Lambda'^n_\alpha, \text{ respectively, and } \zeta(k) \equiv \rho^h/\rho, \eta_n(\Lambda) \equiv \sigma_n^h/\sigma_n, \eta'_n(\Lambda) \equiv \sigma'_n^h/\sigma'_n \text{ with the distribution functions for holes } \rho^h, \sigma_n^h, \text{ and } \sigma'_n^h. \text{ We have introduced an external magnetic field } H \text{ and a chemical potential } A.
\]

Using the Euler-Maclaurin formula and eqs. (8), (10) and (16), we obtain the $1/L$- and $1/L^2$-corrections to the Bethe ansatz equations which determine $f_{1,2}, g_{1,2n}$ and $h_{1,2n}$. Taking a continuum limit, we consequently have,

\[
(1 + \zeta(k))\rho(k)f_1(k) = \frac{\Phi}{2\pi} + \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} \frac{d\Lambda}{\pi} \frac{nu}{(nu)^2 + (\sin k - \Lambda)^2} (g_{1n}(\Lambda)\sigma_n(\Lambda) + h_{1n}(\Lambda)\sigma'_n(\Lambda)),
\]

(15)

\[
\sigma_n(\Lambda)\eta_n(\Lambda)g_{1n}(\Lambda) + \sum_{m=1}^{\infty} A_{nm} * \sigma_m(\Lambda)g_{1n}(\Lambda) = \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{nu \cos k}{(nu)^2 + (\sin k - \Lambda)^2} f_1(k)\rho(k),
\]

(16)
\[ \sigma'_n(\Lambda) \eta'_n(\Lambda) h_{1n}(\Lambda) + \sum_{m=1}^{\infty} A_{nm} * \sigma'_m(\Lambda) h_{1n}(\Lambda) = \frac{n \Phi}{\pi} - \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{nu \cos k}{(nu)^2 + (sin k - \Lambda)^2} f_1(k) \rho(k), \]  
(17)

\[ (1 + \zeta(k)) \rho(k) f_2(k) = \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} \frac{d\Lambda}{\pi} \frac{nu}{(nu)^2 + (sin k - \Lambda)^2} (g_{2n}(\Lambda) \sigma_n(\Lambda) + h_{2n}(\Lambda) \sigma'_n(\Lambda)) \]

\[ + \frac{1}{2} \frac{d}{dk} ((1 + \zeta(k)) \rho(k) f_2') \]

\[ + \sum_{m=1}^{\infty} \int_{-\infty}^{\infty} \frac{d\Lambda}{\pi} \frac{nu(sinh k - \Lambda)}{((nu)^2 + (sin k - \Lambda)^2)^2} (\sigma^2_n(\Lambda) \sigma_n(\Lambda) + h_{1n}(\Lambda) \sigma'_n(\Lambda)), \]  
(18)

\[ (1 + \eta_n(\Lambda)) \sigma_n(\Lambda) g_{2n}(\Lambda) = \frac{1}{2} \int_{-\infty}^{\infty} \frac{d\Lambda}{\pi} ((1 + \eta_n(\Lambda)) \sigma_n(\Lambda) g_{1n}^2(\Lambda)) \]

\[ + \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{nu \cos k}{(nu)^2 + (sin k - \Lambda)^2} f_2(k) \rho(k) + \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{nu(sinh k - \Lambda) \cos k}{((nu)^2 + (sin k - \Lambda)^2)^2} f_2'(k) \rho(k) \]

\[ - \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{nu \sin k}{(nu)^2 + (sin k - \Lambda)^2} f_2'(k) \rho(k) \]

\[ + \sum_{m=1}^{\infty} \int_{-\infty}^{\infty} \frac{d\Lambda'}{2\pi} \Theta'((\Lambda - \Lambda') \frac{g_{2m}(\Lambda') \sigma_m(\Lambda')}{u}) \]

\[ + \lim_{\lambda_0 \to \infty} \frac{1}{48\pi u} \sum_{m=1}^{\infty} \left[ \Theta'((\Lambda - \Lambda_0)/u) (1 + \eta_m(\Lambda_0)) \sigma_m(\Lambda) - \Theta'((\Lambda + \Lambda_0)/u) (1 + \eta_m(-\Lambda_0)) \sigma_m(-\Lambda) \right], \]  
(19)

\[ (1 + \eta'_n(\Lambda)) \sigma'_n(\Lambda) h_{2n}(\Lambda) = \frac{1}{2} \int_{-\infty}^{\infty} \frac{d\Lambda}{\pi} ((1 + \eta'_n(\Lambda)) \sigma'_n(\Lambda) h_{1n}^2(\Lambda)) \]

\[ - \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{nu \cos k}{(nu)^2 + (sin k - \Lambda)^2} f_2(k) \rho(k) - \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{nu(sinh k - \Lambda) \cos k}{((nu)^2 + (sin k - \Lambda)^2)^2} f_2'(k) \rho(k) \]

\[ + \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{nu \sin k}{(nu)^2 + (sin k - \Lambda)^2} f_2'(k) \rho(k) \]

\[ + \sum_{m=1}^{\infty} \int_{-\infty}^{\infty} \frac{d\Lambda'}{2\pi} \Theta'((\Lambda - \Lambda') \frac{h_{2m}(\Lambda') \sigma_m'(\Lambda')}{u}) \]

\[ + \lim_{\lambda_0 \to \infty} \frac{1}{48\pi u} \left[ \Theta'((\Lambda - \Lambda_0)/u) (1 + \eta'_m(\Lambda_0)) \sigma'_m(\Lambda) - \Theta'((\Lambda + \Lambda_0)/u) (1 + \eta'_m(-\Lambda_0)) \sigma'_m(-\Lambda) \right], \]  
(20)

where \( \Theta'(x) \) and \( \Theta''(x) \) are, respectively, the first and second derivative of \( \Theta(x) \). This gives our starting equations for the following discussions. Using these equations, we shall investigate finite-size effects to obtain the Drude weight at finite temperatures.

**III. DRUDE WEIGHT AT FINITE TEMPERATURES**

Here we derive the expression for the Drude weight at finite temperatures using the formulation in the previous section. The Drude weight at finite temperatures is given by the second derivative of the energy spectrum with respect to the AB flux \( \Phi \).

\[ D = \frac{L}{2} \left. \frac{d^2 E_n}{d\Phi^2} \right|_{\Phi=0} \]  
(21)

Here \( \langle \cdots \rangle \) is the thermal average for a canonical ensemble. Note that the above Drude weight \( D \) is different from the second derivative of the free energy, which denotes a Meissner fraction. \[ \square \]
We now consider the second-order term which is,
\[ \frac{E}{L} = - \sum_{j=1}^{N-2M'} (\cos k_j + \mu_0 H + A) + \sum_{n=1}^{\infty} \sum_{\alpha} 4\text{Re} \sqrt{1 - (\Lambda_{\alpha}^{n\Phi} - inu)^2} \]
\[ + 2\mu_0 H \sum_{n=1}^{\infty} n M_n - 2A \sum_{n=1}^{\infty} n M_n'. \]  
(22)

We then expand the energy in powers of $1/L$ using eq. (8),
\[ \frac{E}{L} = E_0 + \frac{E_1}{L} + \frac{E_2}{L^2}. \]  
(23)

The first-order correction term $E_1$ is given by
\[ E_1 = 2 \int_{-\pi}^{\pi} dk \sin kf_1(k) \rho(k) + \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} d\Lambda 4\text{Re} \frac{-(\Lambda - inu)}{\sqrt{1 - (\Lambda - inu)^2}} h_{1n}(\Lambda)\sigma'_{n}(\Lambda). \]  
(24)

Differentiating eqs. (12)-(20) with respect to rapidities, and substituting them into eq. (24), we easily find that $E_1 = 0$. We now consider the second-order term which is,
\[ E_2 = 2 \int_{-\pi}^{\pi} dk \sin kf_2(k) \rho(k) + 2 \int_{-\pi}^{\pi} dk \cos kf_2(k) \rho(k) + \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} d\Lambda 4\text{Re} \frac{-(\Lambda - inu)}{\sqrt{1 - (\Lambda - inu)^2}} h_{2n}(\Lambda)\sigma'_{n}(\Lambda) \]
\[ + \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} d\Lambda 4\text{Re} \left[ \frac{-1}{(1 - (\Lambda - inu)^2)^{3/2}} \right] h_{1n}^2(\Lambda)\sigma'_{n}(\Lambda). \]  
(25)

Using eqs. (12)-(20), we can rewrite this expression as,
\[ E_2 = \frac{T}{2} \int_{-\pi}^{\pi} dk \frac{\rho(k)f_2^2(k)}{\zeta(k)(1 + \zeta(k))} \left( \frac{d\zeta(k)}{dk} \right)^2 + \frac{T}{2} \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} d\Lambda \sigma_n(\Lambda) \frac{g_{1n}^2(\Lambda)}{\eta_n(\Lambda)(1 + \eta_n(\Lambda))} \left( \frac{d\eta_n(\Lambda)}{d\Lambda} \right)^2 \]
\[ + \frac{T}{2} \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} d\Lambda \sigma'_{n}(\Lambda) h_{1n}^2(\Lambda) \left( \frac{d\eta_n'(\Lambda)}{d\Lambda} \right) \left( \frac{d\eta_n'(\Lambda)}{d\Lambda} \right)^2. \]  
(26)

Note that the dependence on the AB flux appears only through $f_1(k), g_{1n}(\Lambda)$, and $h_{1n}(\Lambda)$. We can obtain the Drude weight by differentiating $E_2$ twice with respect to $\Phi$. We see from eqs. (15) to (17) that the equations for $df_1/d\Phi, dg_{1n}/d\Phi$ and $dh_{1n}/d\Phi$ do not depend on $\Phi$. Thus, we have
\[ \frac{d^2 f_1}{d\Phi^2} = \frac{d^2 g_{1n}}{d\Phi^2} = \frac{d^2 h_{1n}}{d\Phi^2} = 0. \]  
(27)

Then the Drude weight is given by
\[ D = \left. \frac{1}{2} \frac{d^2 E_2}{d\Phi^2} \right|_{\Phi=0} \]
\[ = \frac{1}{2} \int_{-\pi}^{\pi} dk \left( (1 + \zeta(k))\rho(k) \frac{df_1}{d\Phi} \right)^2 \frac{d}{dk} \left( \frac{-1}{(1 + e^{\epsilon(k)/T})} \right) \frac{1}{(1 + \zeta(k))\rho(k)} \frac{dn(k)}{dk} \]
\[ + \frac{1}{2} \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} d\Lambda \left( (1 + \eta(\Lambda))\sigma(\Lambda) \frac{dg_{1n}}{d\Phi} \right)^2 \frac{d}{d\Lambda} \left( \frac{-1}{(1 + e^{\epsilon_n(\Lambda)/T})} \right) \frac{1}{(1 + \eta(\Lambda))\sigma(\Lambda)} \frac{dn(\Lambda)}{d\Lambda} \]
\[ + \frac{1}{2} \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} d\Lambda \left( (1 + \eta'(\Lambda))\sigma'(\Lambda) \frac{dh_{1n}}{d\Phi} \right)^2 \frac{d}{d\Lambda} \left( \frac{-1}{(1 + e^{\epsilon_n(\Lambda)/T})} \right) \frac{1}{(1 + \eta'(\Lambda))\sigma'(\Lambda)} \frac{dn(\Lambda)}{d\Lambda}. \]  
(28)
Here we have used the conventional notations, \( \kappa(k) \equiv T \ln \zeta(k) \), \( \varepsilon_n(\Lambda) \equiv T \ln \eta_n(\Lambda) \), and \( \varepsilon'_n(\Lambda) \equiv T \ln \eta'_n(\Lambda) \). In order to simplify the expression, it is convenient to define the following quantities,

\[
\xi_c(k) \equiv 2\pi (1 + \zeta(k)) \rho(k) \frac{df_1}{d\Phi},
\]

\[
\xi_{sn}(\Lambda) \equiv 2\pi (1 + \eta(\Lambda)) \sigma(\Lambda) \frac{dg_{1n}}{d\Phi},
\]

\[
\xi_{bn}(\Lambda) \equiv 2\pi (1 + \eta'(\Lambda)) \sigma'(\Lambda) \frac{dh_{1n}}{d\Phi},
\]

\[
2\pi v_c(k) \equiv \frac{1}{1 + \zeta(k)} \rho(k) \frac{d\kappa(k)}{dk},
\]

\[
2\pi v_{sn}(\Lambda) \equiv \frac{1}{1 + \eta(\Lambda)} \sigma(\Lambda) \frac{d\varepsilon_n(\Lambda)}{d\Lambda},
\]

\[
2\pi v_{bn}(\Lambda) \equiv \frac{1}{1 + \eta'(\Lambda)} \sigma'(\Lambda) \frac{d\varepsilon'_n(\Lambda)}{d\Lambda}.
\]

These quantities have simple physical meanings: \( \xi_c \), \( \xi_{sn} \) and \( \xi_{bn} \) correspond to the dressed charges generalized to finite temperature. \( v_c \), \( v_{sn} \), and \( v_{bn} \) are the velocities for charge excitations, spin excitations, and bound states, respectively. Consequently, we end up with the simple formula for the Drude weight expressed in terms of these quantities,

\[
D = \int_{-\pi}^{\pi} \frac{dk}{4\pi} \frac{d}{dk} \left\{ \frac{1}{1 + e^{\kappa(k)/T}} \right\} \xi_c^2(k)v_c(k) + \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} \frac{d\Lambda}{4\pi} \frac{d}{d\Lambda} \left\{ \frac{1}{1 + e^{\varepsilon_n(\Lambda)/T}} \right\} \xi_{sn}^2(\Lambda)v_{sn}(\Lambda)
\]

\[
+ \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} \frac{d\Lambda}{4\pi} \frac{d}{d\Lambda} \left\{ \frac{1}{1 + e^{\varepsilon'_n(\Lambda)/T}} \right\} \xi_{bn}^2(\Lambda)v_{bn}(\Lambda).
\]

Note that at finite temperatures not only the charge degrees of freedom but also the spin degrees of freedom contribute to the Drude weight. The above formula is the one of our main results in this paper.

To conclude this section, we check that the above formula reproduces the known results by taking zero temperature limit \( T \to 0 \). Since \( \varepsilon_n(\Lambda) > 0 \) for \( n = 2, 3, \ldots \) and \( \varepsilon'_n(\Lambda) > 0 \) for \( n = 1, 2, 3, \ldots \), the contributions from spin excitations with \( n > 1 \) and bound states to the Drude weight vanish for \( T \to 0 \). Moreover from eqs. (13) and (16) we have \( \xi_{1}(\pm B) = 0 \) for \( T \to 0 \) where \( \pm B \) is zeros of \( \varepsilon_1(\Lambda) \). Thus only the contribution from the charge degrees of freedom to the Drude weight survives,

\[
D = \int d\kappa \delta(\kappa) \xi_c^2(k)v_c(k) = K_c v_c.
\]

Here \( K_c = \xi_c^2(k_0)/2 \), and \( v_c = v_c(k_0) \) with \( \kappa(\pm k_0) = 0 \). Then we reproduce the well-known result for zero temperature.

**IV. LOW TEMPERATURE EXPANSION**

**A. Case of half-filling**

In this section, we explicitly derive the temperature dependence of the Drude weight in the case of half-filling at low temperatures. In this case, the system is in the Mott insulating state with the charge excitation gap. Thus we immediately find \( D = 0 \) at zero temperature. However, at finite temperatures it can have finite values as we will see momentarily. We consider the case that \( 2n - A \geq 0 \), \( \mu_0H < 2(\sqrt{1 + w^2} - u) \), and \( 2 - \mu_0H - A \leq 0 \), i.e. the charge excitation is gapful, whereas the spin excitation is gapless. In order to obtain the temperature dependence of the Drude weight, we need to take a thermal average over a canonical ensemble and consider the temperature dependence of the chemical potential \( A \). However, in the presence of the Mott-Hubbard gap, the temperature dependence of \( A \) appears only through that of the Mott-Hubbard gap, which gives a subleading contribution to the temperature dependence of the Drude weight, as is shown below. Thus we can safely ignore the temperature dependence of \( A \).

Following Takahashi’s method, we perform low-temperature expansions. As a result, we find that at low temperatures the Drude weight is mainly controlled by the contributions from the charge excitation, the spin excitation with \( n = 1 \) and the bound-state excitation with \( n = 1 \). At low temperatures eqs. (12), (13) for \( n = 1 \) and (14) for \( n = 1 \) are rewritten as,
\[ \kappa(k) = -2 \cos k - \mu_0 H A + \int_{-B}^{B} \frac{d\Lambda}{\pi} \frac{u}{u^2 + (\sin k - \Lambda)^2} \varepsilon_1(\Lambda) + C_1 T^\gamma, \]  
\tag{37}

\[ \varepsilon_1(\Lambda) = 2\mu_0 H - 4(\text{Re} \sqrt{1 - (\Lambda - iu)^2} - u) - \int_{-B}^{B} \frac{d\Lambda'}{\pi} \frac{2u}{4u^2 + (\Lambda - \Lambda')^2} \varepsilon_1(\Lambda') + C_2 T^\gamma, \]  
\tag{38}

\[ \varepsilon'_1(\Lambda) = 4u - 2A - C_3 T^\gamma e^{\kappa(\pi)/T} \frac{u}{u^2 + \Lambda^2} + C_4 T^\gamma e^{-(4u - 2A)/T}, \]  
\tag{39}

where \( \gamma = 2 \) for \( H \neq 0 \) and \( \gamma = 3/2 \) for \( H = 0 \). \( B \) is defined by the condition \( \varepsilon_1(\pm B) = 0 \). In the absence of magnetic fields, \( H = 0, B \to +\infty \). \( \varepsilon_1(\Lambda) \) is obtained from eq.(38) by using the Wiener-Hopf method. Substituting the solution into eqs.(37) and (39), we obtain \( \kappa(k) \) and \( \varepsilon'_1(\Lambda) \). The generalized dressed charges \( \xi_c, \xi_{s1} \) and \( \xi_{b1} \) are now determined by the derivative of eqs.(47), (46), and (45) with respect to \( \Phi \), which are given in the low temperature limit,

\[ (1 + e^{\kappa(k)/T}) \xi_c(k) = 1 + \int_{-B}^{B} \frac{d\Lambda}{\pi} (\xi_{s1}(\Lambda) + \xi_{b1}(\Lambda)), \]  
\tag{40}

\[ (1 + e^{\varepsilon_1(\Lambda)/T}) \xi_{s1}(\Lambda) = \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{u \cos k}{u^2 + (\sin k - \Lambda)^2} \xi_c(k) - \int_{-B}^{B} \frac{d\Lambda'}{\pi} \frac{2u}{4u^2 + (\Lambda - \Lambda')^2} \xi_{s1}(\Lambda). \]  
\tag{41}

\[ (1 + e^{\varepsilon_1(\Lambda)/T}) \xi_{b1}(\Lambda) = 2 + \int_{-\pi}^{\pi} \frac{dk}{\pi} \frac{u \cos k}{u^2 + (\sin k - \Lambda)^2} \xi_c(k) - \int_{-B}^{B} \frac{d\Lambda'}{\pi} \frac{2u}{4u^2 + (\Lambda - \Lambda')^2} \xi_{b1}(\Lambda). \]  
\tag{42}

Solving these equations we have \( \xi_c(k) = 1 \) and

\[ \xi_{s1}(\Lambda) \sim D_1 \sqrt{T} e^{(2 - \mu_0 H - A + \Delta(B))/T}, \]  
\tag{43}

\[ \xi_{b1}(\Lambda) \sim D_2 e^{-\varepsilon'_1(\Lambda)/T}, \]  
\tag{44}

where

\[ \Delta(B) = \int_{-B}^{B} \frac{d\Lambda}{\pi} \frac{u}{u^2 + \Lambda^2} \varepsilon_1(\Lambda). \]  
\tag{45}

The distribution functions for rapidities, \( \rho(k) \) and \( \sigma_1(\Lambda) \) are given by those for zero temperature. Also, \( \sigma'_1(\Lambda) \) is estimated as

\[ \sigma'_1(\Lambda) \sim C' \sqrt{T} e^{(2 - \mu_0 H - A + \Delta(B))/T} e^{-\varepsilon'_1(\Lambda)/T}. \]  
\tag{46}

Using eqs.(43) and (47)-(48), we finally end up with

\[ D = \frac{\sqrt{T}}{\sqrt{\pi} \tilde{\rho}} e^{-\Delta_{\text{MH}}/T} + O(T e^{2(2 - \mu_0 H - A + \Delta(B))/T}) + O(T^{3/2} e^{-(4u - 2A)/T} e^{(2 - \mu_0 H - A + \Delta(B))/T}), \]  
\tag{47}

where \( \Delta_{\text{MH}} \equiv -2 + \mu_0 H + A - \Delta(B) \) is nothing but the Mott-Hubbard gap, and

\[ \tilde{\rho} = \frac{1}{2\pi} - \int_{-B}^{B} \frac{d\Lambda}{\pi} \frac{u \sigma_0(\Lambda)}{u^2 + \Lambda^2}, \]  
\tag{48}

\[ \sigma_0(\Lambda) = \int_{-\pi}^{\pi} \frac{dk}{8\pi u \cosh \frac{\pi(\Lambda - \sin k)}{2u}}. \]  
\tag{49}

Here the first term of eq.(47), which is most dominant, comes from the charge degrees of freedom, whereas the second and third terms are the contributions from spin degrees of freedom and bound states, respectively. As seen from the above equations, the Drude weight vanishes exponentially at half-filling at low temperatures, reflecting the presence of the Mott-Hubbard gap.
B. Case away from half-filling

We next consider the case away from half-filling in the absence of magnetic fields, i.e. $\kappa(\pi) > 0$. We first estimate the contribution from the charge degrees of freedom. Since we are concerned with a canonical ensemble, we must take into account the temperature dependence of the chemical potential $\mu$ or $k_0$ in the case that the number of electrons

$$\frac{N}{L} = \int_{-\pi}^{\pi} dk \rho(k) + \sum_{n=1}^{\infty} 2n \int_{-\infty}^{\infty} d\Lambda \sigma_n'(\Lambda),$$  \hspace{1cm} (50)$$

is fixed. At low temperatures eq.(50) is approximated by

$$\frac{N}{L} \approx \int_{-\pi}^{\pi} dk \frac{\rho_0(k)}{1 + e^{\epsilon(k)/T}},$$

$$\approx \frac{k_0}{\pi} + 2 \int_{-\infty}^{\infty} \frac{\Lambda}{\pi} \tan^{-1} \frac{\sin k_0 - \Lambda}{U} \sigma_1(\Lambda) + \frac{\pi^2 T^2}{3} \frac{\partial}{\partial \kappa} \left( \frac{\rho_0(k)}{\kappa'(k)} \right) \bigg|_{k = k_0},$$  \hspace{1cm} (51)$$

where $\rho_0(k)$ is the distribution function for $k$ at $T = 0$. Thus we have the temperature dependence of $k_0$,

$$\delta k_0 = k_0 - \tilde{k}_0 = -\frac{\pi^2 T^2}{6 \rho_0(k_0)} \frac{\partial}{\partial \rho_0(k_0)} \left( \frac{\rho_0(k)}{\kappa'(k)} \right) \bigg|_{k = k_0}. \hspace{1cm} (52)$$

Here $\tilde{k}_0$ is $k_0$ at $T = 0$. Then using eq.(53), we obtain the contribution from the charge degrees of freedom to the Drude weight at low temperatures,

$$D_{\text{charge}} \approx \frac{\xi^2_{c}(k_0)v_c(k_0) \pi T^2}{2 \pi} \frac{\partial^2}{\partial \kappa^2} \left( \xi^2_{c}(k)v_c(k) \right) \bigg|_{k = k_0} \approx \frac{K_c v_c}{\pi} + \frac{\delta k_0}{2 \pi} \frac{\partial}{\partial k_0} \left( \xi^2_{c}(k_0)v_c(k_0) \right) \bigg|_{k_0 = \tilde{k}_0} + \frac{\pi T^2}{12} \frac{\partial^2}{\partial \kappa^2} \left( \xi^2_{c}(k)v_c(k) \right) \bigg|_{k = \tilde{k}_0},$$  \hspace{1cm} (53)$$

where the coefficient of the quadratic term is

$$C = \frac{\pi}{12} \left[ \frac{\partial^2}{\partial \kappa^2} \left( \xi^2_{c}(k)v_c(k) \right) \right]_{k = \tilde{k}_0} - \frac{1}{\rho_0(k_0)} \frac{\partial}{\partial \rho_0(k_0)} \left( \frac{\rho_0(k)}{\kappa'(k)} \right) \bigg|_{k = \tilde{k}_0} \frac{\partial}{\partial k_0} \left( \xi^2_{c}(k_0)v_c(k_0) \right) \bigg|_{k_0 = \tilde{k}_0}. \hspace{1cm} (54)$$

Here $\xi_c(k)$ and $v_c(k)$ are calculated at $T = 0$.

In a similar manner, we can evaluate the contributions from the spin degrees of freedom as well as from the bound states. As a consequence we find that they are subdominant compared to the contribution from the charge degrees of freedom at low temperatures. Therefore the leading term of the Drude weight is given by eq.(53). We expect that the expression and its temperature dependence $\sim D(0) + CT^2$ may be general for all integral models with massless excitations.

V. SUMMARY

By using the Bethe ansatz solution, we have obtained the formula for the Drude weight of the Hubbard model at finite temperatures. The present general formulation is not restricted to the Hubbard model, but also applicable to any other integrable models. We have then performed low-temperature expansions both in the case of half-filling as well as away from half-filling. In the case of half-filling, the Drude weight decreases exponentially, as the temperature is lowered, reflecting the presence of the Mott-Hubbard gap. In the case away from half-filling, it behaves like $\sim D(0) + CT^2$, with the coefficient $C$ expressed in terms of the velocity for charge excitations, the dressed charge and their derivatives. Although the essential properties of the Drude weight can be seen through the present low-temperature expansion, it is interesting to obtain its full-temperature dependence by solving the integral equations numerically, which should be done in the future study.
