Anti-amoeba Effect of Branched Medium Chain Fatty Acids and Their Salts on *Acanthamoeba Castellanii*

Haruna Sasaki, Toshinari Koda, and Hiroshi Morita

Abstract—*Acanthamoeba castellanii* is an organism that causes Acanthamoeba keratitis, an infectious disease. *Acanthamoeba* are protists that generally inhabiting soils, freshwater, and sea water, but can also infect the cornea due to dirty water infiltration if contaminated contact lenses are worn. In this study, we focused on four branched medium chain fatty acids—2-ethylhexanoic acid, 3,5,5-trimethylhexanoic acid along with their salts, potassium 2-ethylhexanoate, and potassium 3,5,5-trimethylhexanoate. We examined their antimicrobial effect toward *A. castellanii* and aimed to search for new drugs to be used in contact lens disinfecting solutions. The minimum inhibitory concentrations (MICs) of 2-ethylhexanoic acid and 3,5,5-trimethylhexanoic acid showed growth reduction of 4-log units (99.99% suppression) in *A. castellanii* upon 10 min incubation at 12.5 v/v%. In addition, at a diluted concentration of 6.25 v/v%, 2-ethylhexanoic acid produced a 4-log units reduction at 180 min and for 3,5,5-trimethylhexanoic acid, a 4-log units reduction at 60 min. The MICs of potassium 2-ethylhexanoate showed growth reduction of 4 log units in *A. castellanii* upon 10 min incubation at 2.50 w/v%. However, potassium 3,5,5-trimethylhexanoate showed growth reduction of 4-log units in *A. castellanii* upon 180 min incubation at 5.00 w/v%. Based on the results of MICs, a verification test of 3,5,5-trimethylhexanoic acid and potassium 2-ethylhexanoate was conducted. As a result, approximately 2.1 logarithmic growths were observed in the control consisting of 10% Tween 80 compared to the initial cell number, and the amoeba growth reduction with 3,5,5-trimethylhexanoic acid could not be confirmed up to a concentration of 0.0122 v/v%. Potassium 2-ethylhexanoate salt was not confirmed to reduce amoeba growth up to 0.625 w/v%. However, the amoeba growth reduction could not be confirmed with the tests where control pH-adjusted solution was applied, either. In the light of the above-mentioned results, it was revealed that 3,5,5-trimethylhexanoic acid exhibits the highest anti-amoeba effect among the four tested branched medium chain fatty acids. This result indicated the possibility to use it in contact lens disinfectant solutions as a novel drug against Acanthamoeba keratitis.

Index Terms—2-ethylhexanoic acid, 3,5,5-trimethylhexanoic acid, *a*canthamoeba castellanii, Anti-amoeba effect.

I. INTRODUCTION

*Acanthamoeba castellanii* is an organism that causes an infectious disease called Acanthamoeba keratitis, which was reported for the first time in the UK in 1974 [1] and in Japan in 1988 [2] where over several hundred cases are presumed to occur currently [3]. In recent years, soft contact lenses mainly used by young people, showed an increasing trend [4], [5]. *Acanthamoeba* are protists generally found in soils, freshwater, and seawater [6], yet they can contaminate contact lenses leading to corneal infections due to dirty water infiltration [7]-[9]. Patients with Acanthamoeba keratitis may experience pain presenting with photophobia, ring-like stromal infiltrate, epithelial defects, and lid edema [10]. If Acanthamoeba keratitis is not treated adequately and aggressively, it can lead to loss of vision.

Currently, cold disinfection with hydrogen peroxide solution or multi-purpose solution (MPS) is commonly used for disinfecting contact lenses [11]-[13]. Particularly in the case with MPS; cleaning, rinsing, and disinfection of soft contact lenses can all be performed with the same liquid and it also serves as a preservative solution, making it a commonly used solution [11], [12]. However, the disinfection effect of MPS is weaker than other contact lens disinfection methods, and hypersensitivity may occur, pointing to another disadvantage [12], [13]. Moreover, according to the 2009 National Consumer Center report in Japan, it was shown that anti-amoebic activity of commercially available MPS is very low [14], [15]. MPS contains polyhexanide hydrochloride as a main component [14], [16], [17], however, even after an incubation period of 8 hours, commercially available MPS decreased only 1/10 or less cells, in 4 of 8 strains [14], [15]. In addition, MPS is mainly targeted for eliminating bacteria and fungi, and is hardly considered for preventing eye infections due to amoeba.

Previous studies on anti-amoebic activity have reported antibacterial tests using straight chain fatty acids and their salts [15], in addition to antibacterial tests against fungi [18], bacteria [19] and other microbial agents. Fatty acid salts are carboxylic acid salts of chain hydrocarbons, and are surfactants formed from fatty acids and alkalis with both hydrophilic and hydrophobic properties. Even though fatty acids have no surface activity, as they are similar in structure to fatty acid salts, they have been used as comparative agents for fatty acid salts in previous studies.

However, an anti-amoeba study using branched medium chain fatty acids has not been reported so far. Therefore, in this study, we investigated anti-amoeba effects of branched medium chain fatty acids and their salts against *A. castellanii*. We focused on 2-ethylhexanoic acid and 3,5,5-trimethylhexanoic acid that are members of branched chain fatty acids. Branched chain fatty acids are characterized as colorless and transparent liquids without foreign matter, and are stable viscous liquids excellent in hydrophobicity, dispersibility, heat resistance, and low freezing point. Based...
on these characteristics, they are used in metal soaps, plasticizers, lubricants, surfactants, alkyd resins, fatty acid chlorides, and raw materials for cosmetics, and are excellent candidates for facilitating the exploration and discovery of new drugs. Based on these factors, the anti-amoeba effect of branched medium chain fatty acids and their salts against *A. castellanii* was investigated.

II. METHOD

A. Acanthamoeba Strain and Growth Medium

*Acanthamoeba castellanii* (ATCC 30010) was obtained from the ATCC (American Type Culture Collection, America), and Peptone-yeast-glucose medium (PYG, ATCC 712) was selected as the growth medium. Table I shows the medium composition. Basal medium, inorganic salt solution, and 2 M glucose stock solution were adjusted to pH 6.5 with 10% HCl and 1 M KOH.

| TABLE I: PYG MEDIUM |   |
|----------------------|--|
| **Basal Medium**     |   |
| Tryptone (Becton Dickinson): 3.56 g |   |
| Yeast extract (Becton Dickinson): 0.178 g |   |
| Distilled water: 160 ml |   |
| **Inorganic salt solution** |   |
| a) 0.4 M MgSO$_4$·7H$_2$O (Kanto Chemical Co., Inc.): 2.0 ml |   |
| b) 0.05 M CaCl$_2$ (Junsei Chemical Co., Ltd.): 1.6 ml |   |
| c) 0.005 M Fe(NH$_4$)$_2$(SO$_4$)$_3$·6H$_2$O (Alfa Aesar): 2.0 ml |   |
| d) 0.25 M Na$_2$HPO$_4$ (Kanto Chemical Co., Inc.): 2.0 ml |   |
| e) 0.25 M KH$_2$PO$_4$ (Kanto Chemical Co., Inc.): 2.4 ml |   |
| **2 M Glucose stock solution** |   |
| a) Glucose (Wako Pure Chemical Industries, Ltd.): 3.6 g |   |
| b) Sodium citrate (Nacalai Tesque Co., Ltd.): 0.2 g |   |
| c) Distilled water: 10.0 ml |   |

B. Method of Trophozoite Cultivation

The inorganic salt solution was autoclaved and added to an 300 ml Erlenmeyer flask containing 160 ml basal medium (Table I). Furthermore, 10 ml of 2 M glucose stock solution (Table I) was sterilized by filtration through a 0.25 μm filter and added to the Erlenmeyer flask. Then, 45 ml of the solution in the Erlenmeyer flask was dispensed into petri dishes (φ60 × 45), and 10-fold diluted antibiotic, anti-mycotic solution (10000 units penicillin, 10 mg streptomycin and 25 μg amphotericin B/ml) was added per 5 ml of media. Finally, 500 μl of *A. castellanii* cultivated with PYG medium (3.0 × 10$^5$ cells/ml) was cultured on these dishes for 7 to 14 days at 30°C.

|-----------------------------------------|--|
| Branched chain fatty acid | Structural formula |
| 2-ethylhexanoic acid | ![Structure](image) |
| 3,5,5-trimethylhexanoic acid | ![Structure](image) |

A. Fatty Acids and Their Salts

Two branched chain fatty acids along with their salts were tested in this study. In this study, 2-ethylhexanoic acid and 3,5,5-trimethylhexanoic acid commercial products were tested. Their structural formulae are shown in Table II. For each of the two salts, those provided by Nissan Chemical Corporation were used. As for the concentration, a concentration already adjusted to 10% was used.

B. Preparation of Cell Suspensions

The number of trophozoites from the amoeba suspension produced by using the method described above, was assessed using an optical plastic plankton counter (Matsunami Glass Ind., Ltd., Osaka, Japan). The final amoeba suspension was adjusted to approximately 5.0 x 10$^4$ cells /ml.

C. Assay of Anti-amoeba Activity

A previously prepared and adjusted amoeba suspension of 1 ml was desiccated, and 1 ml of 10% Tween 80 was mixed with 1 ml of the fatty acids with which the pellet was re-suspended. This mixture was incubated at 30°C and used as a control solution. In test solutions with fatty acid salt, a pH-adjusted solution was used instead of Tween 80. Sampling was performed in 500 μl aliquots at 10, 60, and 180 min. The samples were added to microcentrifuge tubes containing 100 μl Hanks’ Balanced Salt Solution (Invitrogen) and 400 μl 0.4% Trypan Blue Stain (Invitrogen), and incubated for 5 min. Five-fold diluted samples were added to an optical plastic plankton counter and were allowed to stand for 5 min. Due to osmotic pressure, the staining solution penetrates dead cells, which are thus stained blue. Therefore, the unstained viable cells were then counted using an optical microscope (ECLIPSE TS100; Nikon). The experiments were repeated at least thrice.

D. Assay of Minimum Inhibitory Concentrations (MICs)

MIC is the minimum concentration required to prevent the growth of microorganisms [20]. Thus, lower MIC values indicate greater drug efficacy. The MICs of fatty acids and fatty acid salts were measured to examine their anti-amoeba activity against *A. castellanii* and samples with the highest activity were determined.

Samples were prepared in 2-fold dilution series (final concentration of fatty acids: 12.5 v/v%, fatty acid salts: 1.25 w/v%), and 400 μl each of sample and amoeba suspension (final concentration of 5.0 x 10$^5$ cells/ml) was taken in a 1.5 ml tube. After 3 h, 500 μl of the sampling solution was transferred in a tube containing 100 μl Hanks’ Balanced Salt Solution and 400 μl of 0.4% Trypan Blue Stain and stained for 5 min. 300 μl of the solution was taken onto an optical plastic plankton counter, to count the number of unstained viable cells using an optical microscope. These results indicated minimum concentrations at which no viable cells were observed, providing the MICs values of each fatty acids and their salts. The experiments were repeated at least thrice.

E. Assessment with Verification Tests

Results demonstrated a higher anti-amoeba activity against *A. castellanii* in 3,5,5-trimethylhexanoic acid and potassium 2-ethylhexanoate. Therefore, verification tests using contact lenses were conducted to evaluate the effectiveness of 3,5,5-trimethylhexanoic acid and potassium.
2-ethylhexanoate in MPS.

The selected amoeba for verification tests was the trophozoite of *A. castellanii*. The “seed 2 week pure” (Seed Co., Ltd.), a type of 2-week disposable soft contact lens was selected as the test lens.

The experiment was conducted according to the method described by Borazjani and Kilvington (2005) [21] and Kilvington *et al.* (1990) [22]. The amoeba suspension (1 ml) adjusted to $3.0 \times 10^3$ cells/ml was added into 12-well plates, and a soft contact lens was immersed and allowed to stand for 2 h. Then, 2 ml of the sample to be tested (10% Tween 80, 3,5,5-trimethylhexanoic acid and pH-adjusted water, potassium 2-ethylhexanoate) was added in another plate and the soft contact lenses were transferred to these sample wells and incubated for 6 h for disinfection. The concentration of 3,5,5-trimethylhexanoic acid was 12.5 v/v%, and the concentration of potassium 2-ethylhexanoate was 1.25 w/v%. Then, the lenses were transferred to other wells containing 1 ml of the *Acanthamoeba* culture medium (PYG medium), detaching the amoeba adhering to the lenses in the wells. The number of viable cells was measured after 7 days of culture at 30°C. An anti-amoebic effect was considered sufficient when the number of viable cells was less or equal to 10 cells/ml. The experiments were repeated at least three times.

### III. RESULTS

#### A. Effect of Fatty Acids and Their MICs on *Acanthamoeba Castellanii*

Fig. 1 shows the time course of the anti-amoeba test of a 2-fold dilution series of the fatty acid, 2-ethylhexanoic acid, against *A. castellanii*.

In addition, at a diluted concentration of 6.25 v/v%, 2-ethylhexanoic acid produced a 4-log units reduction at 180 min and 3,5,5-trimethylhexanoic acid a 4-log unit reduction at 60 min.

#### A. Effect of Fatty Acid Salts and Their MICs on *Acanthamoeba Castellanii*

Fig. 4 shows the time course of the anti-amoeba test of a 2-fold dilution series of potassium 2-ethylhexanoate, the dots show the pH-adjusted solution (control) (x), potassium 2-ethylhexanoate 5.00 w/v% (○), 2.50 w/v% (+), 1.25 w/v% (△), 0.625 w/v% (△), 0.313 w/v% (○). Data were obtained from at least three independent experiments.
2-fold dilution series of fatty acid salt, potassium 2-ethylhexanoic acid, against A. castellanii. Fig. 5 shows the time course of the anti-amoeba test of a 2-fold dilution series of fatty acid salt, potassium 3,5,5-trimethylhexanoic acid, against A. castellanii.

In Fig. 6 (A), as in Fig. 3, vacuole and similar structures were observed, but both (B) and (C) were stained black and the vacuole could not be observed. The MICs of potassium 2-ethylhexanoate showed growth reduction of 4 log units in A. castellanii upon 10 min incubation at 2.50 w/v%. However, potassium 3,5,5-trimethylhexanoate showed growth reduction of 4 log units in A. castellanii upon 180 min incubation at 5.00 w/v%. The pH-adjusted solution (control) had no effect. Figure 6 shows the microscopic images of the cells after 180 min of contact with the sample.

B. Assessment of Verification Tests

Fig. 7 shows the results of verification tests using the 3,5,5-trimethylhexanoic acid. About 2.1 logarithmic growths were observed in the control consisting of 10% Tween 80 when compared to the initial cell number, but 3,5,5-trimethylhexanoic acid's anti-amoeba effect could not be confirmed up to 0.0122 v/v%.

Fig. 8 shows the results of verification tests using the potassium 2-ethylhexanoate. Potassium 2-ethylhexanoate salt could not confirm eliminating amoeba up to 0.625 w/v%. However, the anti-amoeba effect could not be confirmed with the control pH-adjusted solution.

IV. DISCUSSION

The results of this study suggest that the branched medium chain fatty acids have higher anti-amoeba effect on amoebae than their potassium salts. Previous anti-amoeba studies on A. castellanii showed a 4-log reduction in growth when treated with 175 mM potassium caprylate (C8K), potassium caprate (C10K), and potassium laurate (C12K) for 180 min [15]. In addition, cell membrane disruption was observed after mixing the amoeba suspension with C10K or C12K, and the MIC of C10K and C12K was 2.7 mM. Furthermore, in verification tests, both samples showed an anti-amoeba effect at a concentration of 5.5 mM.

In order to calculate the molarity of the sample used in this study, the weight per 1 g of the sample was measured three times, and the molarity was obtained using the average value and the molecular weight of the sample. As a result, the MIC of the anti-amoeba test in this study for 3,5,5-trimethylhexanoic acid (12.5 v/v%) was 705 mM, and for potassium 2-ethylhexanoate (2.50 w/v%) was 139 mM. MIC in the verification tests was 0.689 mM for 3,5,5-trimethylhexanoic acid (0.0122 v/v%) and 34.8 mM for potassium 2-ethylhexanoate (0.625 w/v%).

Contrary to previous ones, in this study, dead cells were confirmed even though the amoeba cell membrane was not ruptured, as shown in Figures 3 and 6. It was difficult to compare our anti-amoeba tests to others because previous studies conducted anti-amoeba tests for 180 min. However, in the verification tests, 3,5,5-trimethylhexanoic acid was found to have an anti-amoeba effect at a concentration of about 1/8 of the concentrations of C10K and C12K from the previous study. From these result, it can be deduced that the anti-amoeba effect of 3,5,5-trimethylhexanoic acid is higher than that of C10K and C12K from the previous study.

Petschow et al. showed the susceptibility of Helicobacter pylori to the bactericidal properties of medium chain monoglycerides and free fatty acids, which may also be a possible model for the mechanism of amoeba cell death [23]. They showed medium chain fatty acids, long chain fatty acids, and unsaturated fatty acids bind to the carrier of the electron transport chain while passing through the outer membrane.
enabling their entry to the cell and cause disruption of the electron transport [23]. This is thought to be due to inhibition of FabI protein, which is a part of the lipid metabolism [24].

In a study by Watanabe [25] on an antimicrobial surfactant, the anionic surfactant was found to adhere to the surface of bacteria; the adsorbed surfactant exhibits affinity to the cell surface and destroys the cell membrane suggesting permeation through the polyprotein membrane. Therefore, it is thought that this resulted in an antibacterial effect.

V. CONCLUSION

Considering the results of this study, we examined the applicability of potassium 2-ethylhexanoate and 3,5,5-trimethylhexanoic acids as agents in contact lens disinfecting solutions. As a result, it was revealed through the verification tests that 3,5,5-trimethylhexanoic acid had an anti-amoebo effect at 0.689 mM and potassium 2-ethylhexanoate at 34.8 mM. However, potassium 2-ethylhexanoate had a high pH, thus it was not possible to clarify the effect of the sample itself in the verification tests. Furthermore, both potassium 2-ethylhexanoate and 3,5,5-trimethylhexanoic acids are considered to cause skin and eye irritations, and as they would directly contact the eyes through soft contact lenses soaked in a disinfectant solution containing these fatty acids, they do not seem applicable. Therefore, this study suggests that it can be used as a disinfectant for hard contact lenses that can be placed to the eyes after rinsing with tap water, once they are disinfected with 3,5,5-trimethylhexanoic acid.
