ABSTRACT

Development of complementary and/or alternative drugs for treatment of hepatitis C virus (HCV) infection is still much needed from clinical and economic points of view. Antiviral substances obtained from medicinal plants are potentially good targets to study. Glycyrrhiza uralensis and G. glabra have been commonly used in both traditional and modern medicine. In this study, extracts of G. uralensis roots and their components were examined for anti-HCV activity using an HCV cell culture system. It was found that a methanol extract of G. uralensis roots and its chloroform fraction possess anti-HCV activity with 50%-inhibitory concentrations (IC50) of 20.0 and 8.0 μg/mL, respectively. Through bioactivity-guided purification and structural analysis, glycycoumarin, glycyrol and liquiritigenin were isolated and identified as anti-HCV compounds, their IC50 being 8.8, 7.2, 4.6 and 16.4 μg/mL, respectively. However, glycyrrhizin, the major constituent of G. uralensis, and its monoammonium salt, showed only marginal anti-HCV activity. It was also found that licochalcone A and glabridin, known to be exclusive constituents of G. inflata and G. glabra, respectively, did have anti-HCV activity, their IC50 being 2.5 and 6.2 μg/mL, respectively. Another chalcone, isoliquiritigenin, also showed anti-HCV activity, with an IC50 of 3.7 μg/mL. Time-of-addition analysis revealed that all Glycyrrhiza-derived anti-HCV compounds tested in this study act at the post-entry step. In conclusion, the present results suggest that glycycoumarin, glycyrol and liquiritigenin isolated from G. uralensis, as well as isoliquiritigenin, licochalcone A and glabridin, would be good candidates for seed compounds to develop antivirals against HCV.

Key words antiviral substance, coumarin, Glycyrrhiza uralensis, hepatitis C virus.
with the viral genome; however, the nonstructural proteins constitute the viral replication complex, where replication of the viral genome takes place. The HCV proteins also play essential roles in the pathological processes associated with HCV infection, such as carcinogenesis and glucose and lipid metabolic disorders (4, 5).

Hepatitis C virus is among the major causative agents of chronic hepatitis, hepatic cirrhosis and hepatocellular carcinoma (5–7). The global prevalence of HCV is >2.5%; thus, about 180 million people are chronically infected with this virus worldwide. A variety of standard treatment regimens using combinations of pegylated interferon, ribavirin and other direct-acting agents, such as HCV-specific inhibitors against NS3 protease and NS5A, have been adopted with considerable success. However, some clinically important issues remain unsolved, such as the emergence of drug-resistant virus and the cost of these drugs. Therefore, development of complementary and/or alternative drugs, especially those from medicinal plants, for treating HCV infection is still much needed from both clinical and economic points of view (8, 9).

Glycyrrhiza uralensis and G. glabra have been widely used as supplementary treatments in both traditional herbal medicine and modern medicine (10, 11). The radix of Glycyrrhiza spp. is commonly known as “gan cao” in Chinese and licorice in English. Bioactive constituents of Glycyrrhiza species can be classified into triterpenoids (such as glycyrrhizic acid), coumarins (such as glycycomararin, glycyrrin and glycyrol), flavones (such as liquiritin and liquiritigenin), chalcones (such as isoliquiritigenin and licochalcone A), isoflavans (such as glabridin), stilbenoids and other miscellaneous compounds (11). Glycyrrhizic acid, also known as glycyrrhizin and considered the principal component of Glycyrrhiza spp., is a glycosylated triterpenoid saponin that consists of one molecule of glycyrrhetinic acid and two molecules of d-glucuronic acid. Upon hydrolysis, the aglycone, 18β-glycyrrhetinic acid (simply called glycyrrhizinic acid), and two molecules of d-glucuronic acid are released. Glycyrrhizin and other compounds isolated from Glycyrrhiza species reportedly have antiviral activity against a variety of viruses, including HIV, herpes simplex virus, influenza virus, severe acute respiratory syndrome coronavirus, hepatitis viruses and enteroviruses (11–15). As for hepatitis viruses, glycyrrhizin has been used to treat liver diseases, including chronic hepatitis B and C (10). Although glycyrrhizin decreases serum alanine aminotransferase concentrations in HCV-infected patients, it does not significantly reduce amounts of HCV RNA (16, 17). It has been reported that a glycyrrhizin-containing preparation reduces hepatic steatosis in transgenic mice expressing the full-length HCV polyprotein (18). Recently, anti-HCV activity of glycyrrhizin in vitro was reported (19, 20). However, clear evidence for it still appears to be lacking.

In this study, we used an HCV cell culture system to examine a methanol extract and a chloroform subfraction of G. uralensis and certain isolated compounds, as well as commercially available purified compounds, such as glycyrrhizin and glycyrrhetinic acid, for their anti-HCV activity. We report here that glycycomararin, glycyrrin, glycyrol and liquiritigenin isolated from G. uralensis showed anti-HCV activity whereas glycyrrhizin showed only a marginal anti-HCV activity. We also found that some other constituents of G. uralensis or of G. inflata and G. glabra, such as isoliquiritigenin, licochalcone A and glabridin, showed anti-HCV activity.

MATERIALS AND METHODS

Cells and viruses

Huh7.5 cells and the plasmid pFL-J6/JFH1 (21) were kindly provided by Dr. C. M. Rice (Rockefeller University, New York, NY, USA). Huh7.5 cells were cultured in Dulbecco’s modified Eagle’s medium supplemented with FBS (Biowest, Nuaillé, France), non-essential amino acids (Invitrogen, Carlsbad, CA, USA), penicillin (100 IU/mL) and streptomycin (100 μg/mL) (Invitrogen) at 37 °C in a 5% CO2 incubator. A cell culture-adapted strain of HCV genotype 2a (J6/JFH1-P47) was prepared as described previously (22) and used in this study at an MOI of 2.0.

Extraction, sub-fractionation and purification of G. uralensis roots

G. uralensis roots were purchased from Tochimoto Tenkaido (Osaka, Japan). A methanol extract of G. uralensis roots was prepared and subjected to purification procedures, as described previously (23–26). In brief, G. uralensis roots were dried at room temperature and pulverized. They were then extracted with methanol at 50 °C for 6 hr. The extracts were filtered and the filtrates concentrated by using an evaporator at temperatures not exceeding 40 °C. The residues obtained were re-suspended in water and successively partitioned between chloroform and n-butanol. The chloroform extract was subjected to recycling preparative HPLC (solvent system, 100% methanol; column, GS-320 + GS-310, 21.5 mm ID × 1000 mm, flow rate; 5.0 mL/min; detection, UV 210 nm: Condition A) to afford 10 fractions (Fr.1 to Fr.10). Fr.7 was subjected to HPLC
separation (solvent system, acetonitrile–water; column, Imtakt Unison UK-C18C (Kyoto, Japan), 4.6 mm ID × 250 mm; flow rate, 2.0 mL/min; detection, UV 254 nm) to give 12 fractions (Fr.7–1 to 7–12) and glycyrrhin (2.5 mg; Fr.7–9). Fr.7–6 was purified by recycling HPLC (Condition A) to afford glycycomarin (0.7 mg). Fr.8–10 were combined and then rechromatographed by HPLC (solvent system, acetonitrile–water; column, Imtakt Unison UK-C18C, 4.6 mm ID × 250 mm; flow rate, 2.0 mL/min; detection, UV 254 nm) to give 15 fractions (Fr.8–1 to Fr.8–15). Fr.8–3 was subjected to recycling HPLC (Condition A) to give liquiritigen (1.2 mg). Fr.8–9 was purified by recycling HPLC (Condition A) to afford glycyrol (1.1 mg). The T-H- and 13C-NMR spectra were measured with a Jeol ECA 500 spectrometer (500 MHz; Tokyo, Japan). HPLC was performed on a JASCOLC-2000 plus system (Tokyo, Japan).

**Chemicals**

Glycyrrhizic acid (cat. no. 074-03481), glycyrrhizic acid mono-ammonium salt n-hydrate (cat. no. 075-02171), glycyrrhetic acid (cat. no. 072-02181) and glabridin (cat. no. 070-04821) were purchased from Wako Pure Chemical Industries (Osaka, Japan). Liquiritin (cat. no. L080502), liquiritigenin (cat. no. 78825) and licochalcone A (cat. no. 68783) were purchased from Sigma–Aldrich (Tokyo, Japan) and isoliquiritigenin (cat. no. I0822) from Tokyo Chemical Industry (Tokyo, Japan). Licorice-saponins G2 (cat. no. P2502) and H2 (cat. no. P2503), and glycyrhrhetic acid 3-O-glucuronide (cat. no. NH080502) were purchased from Funakoshi (Tokyo, Japan). Glycycomarin, glycyrol, glycyrin and liquiritigenin were isolated from *G. uralensis* extracts in this study, as described above.

**Analysis of anti-HCV activity of plant extracts and purified compounds**

Test samples were weighed and dissolved in DMSO to obtain stock solutions at 10 or 30 mg/mL. The stock solutions were stored at −20 °C until used. Huh7.5 cells were seeded in 24-well plates (1.6 × 10⁵ cells/well). HCV was mixed with serial dilutions of the test samples (100, 30, 10, 3 and 1 μg/mL) and inoculated into the cells. After 2 hr, the cells were washed with medium to remove residual virus and further incubated in medium containing the same concentrations of the samples as those during virus inoculation. In time-of-addition experiments, treatment with the samples was performed only during or after virus inoculation in order to assess the mode of action of the samples examined. Culture supernatants were collected 1 and 2 days post-infection and titrated for virus infectivity, as described below. Virus and cells treated with medium containing 0.1% DMSO served as controls. Percent inhibition of the virus infectivity for each dilution of the samples was calculated by comparison with mock-treated controls and IC₅₀ determined.

**Virus titration**

Virus samples were diluted serially 10-fold in complete medium and inoculated onto Huh7.5 cells seeded on glass coverslips in a 24-well plate. After virus adsorption for 2 hr, the cells were washed with medium to remove residual virus and cultured for 24 hr. The virus-infected cells were stained with an indirect immunofluorescence method as reported previously (27). In brief, the virus-infected cells were washed with PBS, fixed with 4% paraformaldehyde for 15 min and permeabilized with 0.1% Triton X-100 in PBS for 15 min at room temperature. After being washed three times with PBS, the cells were incubated with HCV-infected patient’s serum for 1 hr, followed by incubation with FITC-conjugated goat anti-human IgG (MBL, Nagoya, Japan). The cells were counterstained with Hoechst 33342 (Molecular Probes, Eugene, OR, USA) for 5 min and HCV-infected cells were counted under a BZ-9000 fluorescence microscope (Keyence, Osaka, Japan).

**Cytotoxicity assay**

The cytotoxicity of the samples was assessed by WST-1 assay as described previously with a slight modification (27). In brief, Huh7.5 cells in 96-well plates were treated with serial dilutions of the samples or 0.1% DMSO as a control for 48 hr. At the end of the treatment, 10 μL of WST-1 reagent (Roche, Mannheim, Germany) was added to each well and the cells cultured for 1 hr. The WST-1 reagent is absorbed by the cells and converted to formazan by mitochondrial dehydrogenases. The amount of formazan, which correlates with the number of living cells, was determined by measuring the absorbance of each well using a microplate reader at 450 and 630 nm. Percent cell viability compared to the control was calculated for each dilution of the samples and CC₅₀ were determined.

**Immunoblotting**

Cells were lysed with an SDS sample buffer, after which equal amounts of protein were subjected to SDS–polyacrylamide gel electrophoresis and transferred onto a polyvinylidene difluoride membrane (Millipore, Bedford, MA, USA), as described previously (28, 29). The membranes were incubated with the respective primary
antibodies. The primary antibodies used were mouse monoclonal antibodies against HCV NS3 and GAPDH (Millipore). Horseradish peroxidase-conjugated goat anti-mouse immunoglobulin (Invitrogen) was used to visualize the respective proteins by means of an enhanced chemiluminescence detection system (ECL; GE Healthcare, Buckinghamshire, UK).

**Real-time quantitative RT-PCR**

Real-time quantitative RT-PCR was performed as described previously (28, 29). In brief, total RNA was extracted from the cells using a ReliaPrep RNA cell miniprep system (Promega, Madison, WI, USA) according to the manufacturer’s instructions. One microgram of total RNA was reverse transcribed using a GoScript Reverse Transcription system (Promega) with random primers and subjected to real-time quantitative PCR analysis using SYBR Premix Ex Taq (TaKaRa, Kyoto, Japan) in a MicroAmp 96-well reaction plate and an ABI PRISM 7500 system (Applied Biosystems, Foster City, CA, USA). The HCV-specific primers to amplify an NS5A region of the viral genome were 5'-AGACGTATTGAGGTCCATGC-3' (sense) and 5'-CCGCAGGACGGTGCTGATA-3' (antisense). Human GAPDH gene expression was measured using primers 5'-GCCATCAATGACCCCTTCATT-3', which served as an internal control.

**RESULTS**

**Anti-HCV activity of a methanol extract and sub-fractions of G. uralensis roots**

First, we examined a crude methanol extract of *G. uralensis* roots for anti-HCV activity using the HCV J6/JFH1-P47 strain and Huh7.5 cells. The IC50 and CC50 values of the crude methanol extract were 20.0 and 300 μg/mL, respectively, the selectivity indexes (SI: CC50/IC50) being 15 (Table 1). We further partitioned the methanol extract using different solvents and found that the anti-HCV activity was concentrated into a chloroform partition, whose IC50 and CC50 were 8.0 and 93 μg/mL, respectively, the SI being 11.6.

**Table 1.** Anti-HCV activity (IC50), cytotoxicity (CC50) and selectivity index (SI) of extracts of *G. uralensis* roots

| Sample               | IC50 (μg/mL) | CC50 (μg/mL) | SI  |
|----------------------|--------------|--------------|-----|
| Methanol extract     | 20.0         | 300          | 15.0|
| Chloroform partition | 8.0          | 93           | 11.6|
| n-butanol partition  | 17.5         | 250          | 14.3|
| Water partition      | 95.0         | >500         | >5.3|

Next, we sub-fractionated the chloroform partition by using recycling HPLC and examined the sub-fractions for anti-HCV activity. We found significant anti-HCV activity with fractions 6–10, IC50 ranging between 2.9 and 4.9 μg/mL (Table 2). We further tried to purify a major component(s) in fractions 6–10 by using recycling HPLC: we identified glycycomarin (30), glycyrin (31), glycyrol (32) and liquiritigenin (33) by NMR spectrum analysis (data not shown).

**Anti-HCV activity of *G. uralensis*-derived purified compounds and related chemical compounds obtained from other *Glycyrrhiza* species**

We then examined the purified compounds obtained from the *G. uralensis* extracts (glycycomarin, glycyrin, glycyrol and liquiritigenin) and other *Glycyrrhiza*-derived chemical compounds, such as glycyrrhizin and its derivatives. We found that glycyrrhizin (glycyrrhizic acid) and its monoammonium salt (glycyrrhizic acid monoammonium), the latter being more water-soluble than the former, possessed only marginal anti-HCV activity, IC50 values being 180 and 320 μg/mL, respectively (Table 3). The aglycone of glycyrrhizin, glycyrrhetic acid, showed more significant anti-HCV activity than did glycyrrhizin, its IC50 being 40 μg/mL. It should be noted that their anti-HCV activities were weaker than those of the recycling HPLC fractions 6–10 of the *G. uralensis* extract. The monoglucuronide form of glycyrrhizin, glycyrrhetic acid 3-O-glucuronide, did not show significant anti-HCV activity at the concentration tested. These results suggest that another compound(s) in fractions 6–10 was responsible for the anti-HCV activity. Two other saponins tested in this study, licorice-saponins G2 and H2, did not show detectable anti-HCV activity. On the other hand, coumarins, such as
glycycoumarin, glycyrin and glycyrol, which were isolated in this study (purity >90%) from the G. uralensis extracts, showed potent anti-HCV activity, IC\textsubscript{50} being 4.6–8.8 mg/mL. Liquiritigenin, which was also isolated from the G. uralensis extracts, showed weaker anti-HCV activity than the coumarins. Also, isoliquiritigen, licochalcone A and glabridin exhibited potent anti-HCV activity, their IC\textsubscript{50} being 3.7, 2.5 and 6.2 \(\mu\)g/mL, respectively. It should be noted that licochalcone A and glabridin have been reported to be absent in G. uralensis but present in G. inflata and G. glabra (34).

**Mode-of-action of G. uralensis-derived isolated compounds and related compounds obtained from other Glycyrrhiza species**

To determine whether the anti-HCV effects of the compounds of Glycyrrhiza species are exerted on the entry or post-entry stage, we performed the following time-of-addition experiments.

1. HCV was mixed with a test compound and the mixture inoculated into the cells. After virus adsorption for 2 hr, the residual virus and test sample were removed and the cells re-fed with fresh medium without the test sample for 46 hr. This experiment examines the antiviral effect at the entry step.

2. HCV was inoculated into the cells in the absence of a test sample. After virus adsorption for 2 hr, the residual virus was removed and the cells treated with the test samples for 46 hr. This experiment examines the antiviral effect at the post-entry step.

3. As a positive control, HCV mixed with the test sample was inoculated into the cells. After virus adsorption for 2 hr, the residual virus and test sample were removed and the cells treated with the test samples for 46 hr.

We found that all the Glycyrrhiza species-derived compounds as well as the chloroform partition of the G. uralensis extract exerted their antiviral effects after virus inoculation (Table 4). These results suggest that all the anti-HCV compounds of Glycyrrhiza species tested in this study, namely, glycycoumarin, glycyrin, glycyrol, liquiritigenin, isoliquiritigenin, licochalcone A and glabridin, as well as the chloroform extract, act primarily at the post-entry step.

**Inhibition of HCV RNA replication and HCV protein synthesis by glycycoumarin, glycyrin, and glycyrol obtained from G. uralensis**

To further confirm that G. uralensis-derived compounds exert their anti-HCV activities at the post-entry step, Huh7.5 cells were inoculated with HCV for 2 hr, followed by treatment with each of compounds for 1–2 days. The results obtained clearly demonstrated that glycycoumarin, glycyrin and glycyrol inhibit HCV RNA replication, resulting in decreased HCV protein replication.

### Table 3. Anti-HCV activity (IC\textsubscript{50}), cytotoxicity (CC\textsubscript{50}) and selectivity index (SI) of G. uralensis- and other Glycyrrhiza spp-derived compounds

| Sample                     | IC\textsubscript{50} (\(\mu\)g/mL) | CC\textsubscript{50} (\(\mu\)g/mL) | SI  |
|---------------------------|-----------------------------------|-----------------------------------|-----|
| **Triterpenoids**         |                                   |                                   |     |
| Glycyrrhizin              | 180                               | 560                               | 3.1 |
| Glycyrrhizic acid monoammonium | 320                           | 690                               | 2.2 |

| Glycyrol (isolated)       | 4.6                               | 35.5                              | 7.7 |
| **Flavonoids**            |                                   |                                   |     |
| **Flavanones**            |                                   |                                   |     |
| Liquiritin                | 75.0                              | 570                               | 7.6 |
| Liquiritigenin            | 16.4                              | 125                               | 7.6 |
| **Chalcones**             |                                   |                                   |     |
| Isoliquiritigenin         | 3.7                               | 11.0                              | 3.0 |
| Licochalcone A\textsuperscript{†} | 2.5                        | 20.0                              | 8.0 |
| **Isoflavan**             |                                   |                                   |     |
| Glabridin\textsuperscript{†} | 6.2                          | 22.7                              | 3.7 |

\textsuperscript{†}Not detected in G. uralensis (34). \textsuperscript{‡}No detectable HCV inhibition at 30 \(\mu\)g/mL. na, not applicable.

### Table 4. Mode-of-action analysis of anti-HCV activities of G. uralensis- and other Glycyrrhiza spp.-derived compounds

| Compound                  | Conc. (mg/mL)\textsuperscript{†} | Anti-HCV activity (% inhibition) |
|---------------------------|-----------------------------------|---------------------------------|
|                          | During\textsuperscript{‡} | After\textsuperscript{‡} | During & after\textsuperscript{‡} |
| Chloroform partition      | 30 | 28.6 | 100 | 100 |
| Glycycoumarin             | 20 | 16.7 | 100 | 100 |
| Glycyrrhizin              | 15 | 18.4 | 98.3 | 99.6 |
| Glycyrol                  | 10 | 21.3 | 100 | 100 |
| Liquiritigenin            | 30 | 15.5 | 90.0 | 87.2 |
| Isoliquiritigenin         | 8  | 14.1 | 91.0 | 82.5 |
| Licochalcone A\textsuperscript{†} | 5   | 0    | 94.4 | 93.8 |
| Glabridin\textsuperscript{†} | 12  | 0    | 91.0 | 93.8 |

\textsuperscript{†}The concentrations of each compound used were 2 \(\times\) IC\textsubscript{50}. \textsuperscript{‡}Treatment with the compound was administered only during, only after or both during and after virus inoculation.
synthesis as demonstrated by both real-time quantitative RT-PCR and immunoblotting analyses (Fig. 1a, b). We also confirmed that production of HCV infectious particles is inhibited by glycycomarin, glycyrin and glycyrol at 1 and 2 days post-infection (Fig 1c).

**DISCUSSION**

*Glycyrrhiza* species possess a variety of bioactive compounds, such as: (i) triterpenoids, for example, glycyrrhizin, glycyrrhetic acid 3-0-glucuronide, glycyrrhetic acid and various licorice-saponins; (ii) coumarins, for example, glycycomarin, glycyrin and glycyrol; (iii) flavonones, for example, liquiritin and liquiritigenin; (iv) chalcones, for example, isoliquiritigenin and licochalcone; (v) isoflavans, for example, glabridin; (vi) stilbenoids, for example, dihydrostilbenes; and other miscellaneous compounds (11). In this connection, flavonones, chalcones and isoflavans are members of flavonoids.

*Fig. 1. Effects of glycycoumarin, glycyrin and glycyrol isolated from *G. uralensis* on HCV RNA replication and protein synthesis.

(a) Huh 7.5 cells infected with HCV J6/JFH1 and treated with either glycycomarin (20 μg/mL), glycyrin (15 μg/mL), glycyrol (10 μg/mL) or left untreated were subjected to western blot analysis using monoclonal antibody against the HCV NS3 protein at 1 and 2 days post-infection. GAPDH served as an internal control to verify equal amounts of sample loading. Signal intensities of NS3 were normalized to the corresponding GAPDH signal. (b) Amounts of HCV RNA in the cells described in (a) were measured by real-time quantitative RT-PCR analysis. These amounts were normalized to GAPDH mRNA expression. Data represent means ± SEM of data from two independent experiments. The value for the untreated control at 1 day post-infection is arbitrarily expressed as 1.0. *P* < 0.001, compared with the control. (c) Amounts of HCV infectious particles in the supernatants of the cultures described in (a) and (b) were determined: data for glycycomarin, glycyrin, glycyrol and the untreated control are shown. Data represent means ± SEM of data from two independent experiments. *P* < 0.05; †*P* < 0.01, compared with the untreated control; dpi, days post infection.*
Glycyrrhizin is the major constituent of *Glycyrrhiza* species, representing 1–9% of the total (14). Glycyrrhizin and other compounds isolated from *Glycyrrhiza* species reportedly possess antiviral activity against a variety of viruses (11–15). With regard to HCV, it was recently reported that glycyrrhizin inhibits HCV infection in Huh-7 cells (19, 20). On the other hand, controversial observations have been reported in clinical settings; namely, that glycyrrhizin has no significant effect on amounts of HCV RNA whereas it reduces serum alanine aminotransferase concentrations in HCV-infected patients (16, 17). These apparently contradictory findings might be explained by a membrane-stabilizing effect of glycyrrhizin; clear evidence for antiviral activity of glycyrrhizin is still lacking (10). In the present study, we observed that glycyrrhizin and glycyrrhizic acid monoafoxamine showed only marginal anti-HCV activity (Table 3). Glycyrhetic acid showed significant anti-HCV activity. However, their anti-HCV activities were significantly weaker than that of the HPLC fractions obtained from *G. uralensis* extract. On the other hand, we found that certain coumarins, such as glycyccoumarin, glycyrin and glycyrol, and a flavanone, liquiritigenin, isolated from *G. uralensis*, as well as other compounds contained in *Glycyrrhiza* species, possess potent anti-HCV activities. Mode-of-action analysis revealed that all the *Glycyrrhiza*-derived anti-HCV compounds tested act primarily at the post-entry step. Consistent with our observations, other researchers have also reported that two flavonoids, isoliquiritigenin and glycyrourmarin, extracted from *Glycyrrhiza radix*, either *G. uralensis* or *G. glabra*, inhibit replication of an HCV subgenomic RNA replicon *in vitro* (35). The IC₅₀ values of isoliquiritigenin and glycyccoumarin against HCV subgenomic replicon were 6.2 and 15.5 μg/mL, respectively. On the other hand, to the best of our knowledge, there are no published reports so far regarding anti-HCV activities of glycyrin and glycyrol. It has been reported that glycyrin, which is known to possess peroxisome proliferator-activated receptor-γ ligand-binding activity, shows antibacterial activity against *Streptococcus pyogenes*, *Haemophilus influenzae* and *Moraxella catarrhalis* (36–38). Glycyrin reportedly exerts anti-inflammatory effects by binding to calcineurin to inhibit its activity (39, 40). However, the possible antimicrobial activity of glycyrol has not been reported. Further study is needed to elucidate the detailed mechanism of anti-HCV activities of glycyrin and glycyrol, and also possible antiviral activities against viruses other than HCV.

In conclusion, our results suggest that glycycoumarin, glycyrin, glycyrol and liquiritigenin isolated from *G. uralensis*, as well as isoliquiritigenin, licochalcone A and glabridin, would be good candidates for seed compounds to develop antivirals against HCV.

**ACKNOWLEDGMENTS**

The authors are grateful to Dr. C. M. Rice (Rockefeller University, New York, NY, USA) for providing Huh7.5 cells and pFL-J6/JFH1. This study was supported in part by Science and Technology Research Partnerships for Sustainable Development (SATREPS) from Japan Science and Technology Agency (JST) and Japan International Cooperation Agency (JICA). This study was also carried out as part of the Japan Initiative for Global Research Network on Infectious Diseases (J-GRID), Ministry of Education, Culture, Sports, Science and Technology, Japan.

**DISCLOSURE**

The authors have no conflicts of interest to declare.
