Stent Retriever Thrombectomy in Patients Who Are Ineligible for Intravenous Thrombolysis: A Multicenter Retrospective Observational Study

F. Dorn, S. Prothmann, M. Patzig, H. Lockau, C. Kabbasch, O. Nikoubashman, T. Liebig, C. Zimmer, H. Brückmann, M. Wiesmann, H. Stetefeld, H. Poppert, A. Reich, L. Kellert, and G. Fesl

ABSTRACT

BACKGROUND AND PURPOSE: Intravenous thrombolysis with rtPA is the standard of care for patients with acute ischemic stroke within 4.5 hours after symptom onset. However, a considerable number of patients are ineligible for IV thrombolysis due to various contraindications. Recent studies have proved the superiority of mechanical thrombectomy for patients with large-vessel occlusions in combination with IV rtPA compared with IV rtPA alone. We aimed to demonstrate the efficacy of mechanical thrombectomy for patients who are ineligible for IV rtPA.

MATERIALS AND METHODS: Patients from the stroke registries of 4 dedicated centers who were treated with mechanical thrombectomy from January 2010 to October 2014 were retrospectively evaluated. Inclusion criteria were the following: acute stroke due to proved large-artery occlusion, ineligibility for IV thrombolysis, and a timeframe of ≤4.5 hours between stroke and the start of mechanical thrombectomy. Recanalization success, periprocedural complications, clinical outcome, and hemorrhages were evaluated.

RESULTS: One hundred thirty endovascular recanalization procedures were identified. The locations were the following: proximal ICA in 17 (13.1%), terminus ICA in 25 (19.2%), M1 segment in 77 (59.2%), and M2 segment in 11 (8.5%). TICI 2b/3 results were achieved in 101 (77.7%), and an mRS score of 0–2 in 47 patients (37.9%). There was a significant correlation between TICI 2b/3 results and good clinical outcomes (87.2% versus 6.8%; P = .048). A good clinical result was most frequent when recanalization was achieved within 4.5 hours (37/74 = 50% versus 10/50 = 20.0%; P = .001). Symptomatic hemorrhage occurred in 13.1% of patients; mortality was 24.2%. Periprocedural complications were recorded in 10 patients (7.7%).

CONCLUSIONS: Mechanical thrombectomy can achieve good clinical outcomes in patients with acute large-artery occlusion ineligible for IV thrombolysis, in particular when recanalization is reached early.

ABBREVIATIONS: ESCAPE = Endovascular Treatment for Small Core and Anterior Circulation Proximal Occlusion With Emphasis on Minimizing CT to Recanalization Times; EXTEND IA = Extending the Time for Thrombolysis in Emergency Neurologic Deficits–IntraArterial; MR CLEAN = Multicenter Randomized Clinical Trial of Endovascular Treatment for Acute Ischemic Stroke in the Netherlands; SWIFT PRIME = Solitaire With the Intention for Thrombectomy as Primary Endovascular Treatment Trial; REVASCAT = Randomized Trial of Revascularization with the Solitaire FR Device Versus Best Medical Therapy in the Treatment of Acute Stroke Due to Anterior Circulation Large Vessel Occlusion Presenting within Eight Hours of Symptom Onset.

Intravenous treatment with recombinant tissue-plasminogen activator has been proved effective and has been the standard therapy for patients with acute ischemic stroke within 4.5 hours after symptom onset for many years. However, the percentage of patients eligible for treatment with IV thrombolysis is limited, not only because of the restricted time window but also due to various medical conditions such as recent surgery, anticoagulation, coagulation abnormalities, and history of intracranial hemorrhage.

Patients with acute stroke symptoms secondary to a large-artery occlusion are at high risk of poor clinical outcome. Furthermore, they are known to respond poorly to IV rtPA alone.

During the past decade, several endovascular techniques have been established to improve the success of recanalization and thus the clinical outcomes of these patients, including intra-arterial thrombolysis, mechanical thrombectomy, and permanent stent angioplasty. Fully retrievable stent-based thrombectomy devices (stent retrievers) were introduced in 2008 and today are available.
the technical standard of care for endovascular recanalization treatment in most stroke centers. While several studies and case series have shown high recanalization success of >80%–90%,

the first randomized trials proving a clear clinical benefit compared with sole IV therapy were published only recently. The aim of this study was to complement the existing data by proving the efficacy of endovascular treatment for the subgroup of patients with large-artery occlusions located in the anterior circulation who are ineligible for primary IV thrombolysis within a time window of 4.5 hours.

MATERIALS AND METHODS

Patient Selection

From the stroke registries of 4 stroke centers, we retrospectively evaluated all patients who underwent endovascular therapy between January 2010 and October 2014 and met the following criteria: acute stroke symptoms secondary to large-artery occlusion and contraindications for IV thrombolysis despite a time from symptom onset to the start of endovascular therapy of ≤4.5 hours. One-hundred eight patients (83.1%) underwent the CT stroke protocol, and 22 patients (16.9%), MR imaging.

The decision for treatment for all patients was based on the clinical presentation and the imaging findings. A team of stroke neurologists examined all patients on admission, and the National Institutes of Health Stroke Scale scores were recorded. The patients included in this series had an NIHSS score of at least 10 or fluctuating symptoms. All patients underwent CT or MR imaging before treatment. If possible, multiparametric imaging was performed by using CT/CT angiography and CT perfusion imaging or MR imaging/MR angiography, including the acquisition of FLAIR images, diffusion-weighted images, and a gradient-echo T2* sequence. Imaging criteria for exclusion from endovascular therapy were visible infarction of more than one-third of the vessel territory, no relevant mismatch on CT perfusion imaging, and evidence of hemorrhage. There was no limit to the patient age.

Procedural Data

Final reperfusion success was rated on the basis of the Thrombolysis In Cerebral Infarction scale. Successful reperfusion was defined as TICI scores 2b and 3. The start of angiography was defined as the time of the femoral artery puncture, and the first procedural step involved the following stent retrievers: Solitaire FR (Covidien, Irvine, California) in 88 (67.7%), Trevo/Trevo ProVue (Stryker, Kalamazoo, Michigan) in 32 (24.6%), pREset thrombus retriever (Phenox, Bochum, Germany) in 7 (5.4%), and a combination of Solitaire and Trevo in 3 procedures (2.3%).

Follow-Up Imaging and Clinical Outcome

All patients underwent CT and/or MR imaging at 18 ± 6 hours after the intervention. The images were rated for hemorrhagic transformation or cerebral hemorrhage. According to the criteria of the European Cooperative Acute Stroke Study III, symptomatic hemorrhage was defined as any intracranial hemorrhage with clinical deterioration, as indicated by an NIHSS score that was >4 points or more than the value at baseline.

Good clinical outcome after 3 months was defined as an mRS of 0–2.

Statistical Analysis

Statistical analysis was performed by using SPSS 22.0.0.0 (IBM, Armonk, New York). To test categoric variables for differences, the χ² test was performed. Mann-Whitney U tests and Student t tests were used for comparison of continuous variables. A P value of < .05 was statistically significant.

RESULTS

We identified 130 patients with large-vessel occlusion in the anterior circulation who underwent endovascular recanalization procedures within 4.5 hours after symptom onset and were ineligible for IV thrombolysis. Table 1 gives an overview of the relevant patient data. The mean age was 68.8 years (range, 18–90 years), 64 patients were women (49.2%), and 66 patients (50.8%) were men. The occlusions were located as follows: the proximal ICA in 17 (13.1%), ICA terminus in 25 (19.2%), proximal M1 segment in 71 (54.6%), postbifurcal M1 segment in 6 (4.6%), and M2 segment in 11 (8.5%). A TICI 2b or 3 recanalization result was achieved in 101/130 patients (77.7%). Anticoagulation with phenprocoumon was the most common contraindication for IV thrombolysis (44 patients, 33.8%). Twenty-one patients (16.2%) had a recent history of stroke with corresponding lesions on MR imaging, and 23 patients (17.7%) had a history of recent surgery. Ten patients (7.7%) with evidence for an extracranial occlusion of the ICA were not treated with IV thrombolysis but with antiplatelet medication in preparation for stent placement to reduce the risk of hemorrhage, and 6 patients (4.6%) were under full-dose heparin for numerous disorders. Two patients (1.5%) had not received IV rtPA due to epileptic onset of stroke symptoms; 5 (3.8%), because of known metastasizing cancer; 2 (1.5%), because of gastrointestinal bleeding; 2 (1.5%), because of previous trauma; 3 (2.3%), because of a history of intracranial hemorrhage; 1 (0.8%), because of diagnosed coagulative disorder; and 1 (0.8), because of an intracranial aneurysm detected by CT angiography. In 10 patients (7.7%), contraindication could not be evaluated. Table 2 gives a detailed overview of the contraindications.

The NIHSS score at admission was available in 120/130 patients (92.3%). The mean NIHSS score was 16.32 ± 6.40 (minimum, 2 with fluctuating symptoms; maximum, 34). Modified Rankin Scale scores after 3 months were available in 124/130 patients (95.4%). A good clinical outcome (mRS 0–2) was achieved.
A good recanalization was achieved within 4.5 hours compared with patients with longer recanalization times (37/74 = 50% versus 10/50 = 20.0%; P = .001). If recanalization was achieved within 6 hours from onset (n = 107), 43 patients (40.2%) had a good outcome, whereas in only 4 of 17 patients (23.5%) exceeding the time window of 6 hours was a good outcome noted (P = .085).

The mean number of passages was 3.3.1–15 A good recanalization result (TICI 2b or 3) was most likely in procedures with only 1 stent retriever passage compared with procedures with ≥2 stent retriever passages (25/27 = 92.6% versus 76/103 = 73.8%; P = .039). Furthermore, the chance for a good clinical outcome was significantly higher after a recanalization that required only 1 passage (16/26 = 61.5% versus 31/98 = 31.6%; P = .007).

Altogether, intracranial hemorrhage was detected in 37 patients (28.5%), of whom 17 had symptomatic hemorrhages (13.1%). Intracranial hemorrhage occurred in 4/44 patients (9.1%) who were under sufficient anticoagulation with phenprocoumon at the time of stroke (international normalized ratio > 1.7) and in 3/6 patients who were under effective IV heparin at the time of stroke (50.0%). The incidence of hemorrhage was 66.7% (2/3) in patients with a history of intracerebral hemorrhage, 13.0% in patients with history of recent surgery (3/23), 14.3% (3/21) in patients with recent ischemic stroke, and 20.0% (1/5) in patients who were not eligible for IV thrombolysis because of metastasizing cancer. The 1 patient with a previously diagnosed coagulative disorder did not develop hemorrhage. None of the patients who received antiplatelet medication for subsequent extra- or intracranial stent placement experienced hemorrhage. The mortality rate after 3 months was 24.2% (30/124 patients). Periprocedural complications occurred in 10 patients (7.7%): subarachnoid hemorrhage in 6 (4.6%), thrombus lost with occlusion of a previously nonaffected territory (A2 segment in 1 patient [0.8%], dissection in 1 [0.8%], and loss of the device in 2 [1.6%]).

**DISCUSSION**

To the best of our knowledge, we present the largest series of patients with acute occlusions of anterior large intracranial arteries who were ineligible for IV treatment and were primarily referred to sole endovascular therapy by using stent retrievers. So far, retrospective studies and prospective trials providing evidence for the benefit of endovascular treatment in this specific patient group are nonexistent. The Thrombectomy in Patients Ineligible for IV tPA trial (THRIll) was planned with the intention of showing a benefit of stent retriever based thrombectomy in patients who were ineligible for IV fibrinolysis, but enrollment was stopped and the results of this multicentric German/Austrian study are not available.26

Since the introduction of stent retrieval in 2008,13 several case series have proved the technical effectiveness of the method, with potentially high rates of successful recanalization in patients with acute stroke symptoms secondary to large-vessel occlusion. Furthermore, the superiority of stent retrievers in terms of revascularization abilities and clinical success in

**Table 2: Summary of contraindications against IV thrombolysis**

| Contraindication                        | No. of Patients (n = 130) |
|-----------------------------------------|----------------------------|
| Phenprocoumon (INR > 1.7)               | 44 (33.8%)                 |
| Recent surgery                          | 23 (17.7%)                 |
| Recent stroke                           | 21 (16.2%)                 |
| Emergency stentangioplasty              | 10 (7.7%)                  |
| IV heparin                              | 6 (4.6%)                   |
| Metastasizing cancer                    | 5 (3.8%)                   |
| History of ICH                          | 3 (2.3%)                   |
| Previous trauma                         | 2 (1.5%)                   |
| Epileptic onset                         | 2 (1.5%)                   |
| Gastrointestinal bleeding               | 2 (1.5%)                   |
| Coagulative disorder                    | 1 (0.8%)                   |
| Intracranial aneurysm                   | 1 (0.8%)                   |
| Not evaluable                           | 10 (7.7%)                  |

Note:—INR indicates international normalized ratio; ICH, intracerebral hemorrhage.

---

in 47/124 patients (37.9%). The recanalization was successful (TICI 2b/3) in 101/130 patients (77.7%). Forty-one (87.2%) of the 47 patients with a good clinical outcome after 3 months had TICI 2b/3 recanalization, whereas only 6 had a TICI 0–2a result (6.8%; P = .048). The mean time from stroke onset to groin puncture was 175.7 ± 45.4 minutes (minimum, 65 minutes; maximum, 270 minutes), and the mean time from stroke onset to final recanalization was 246.0 ± 71.7 minutes (minimum, 94; maximum, 432 minutes). A favorable clinical outcome was more frequent in patients with an occlusion of the M2 (5/11 patients, 45.5%) and M1 segments (30/76 patients, 40.5%) and was least frequent in patients with an occlusion of the terminus ICA (6/24, 25.0%). A good clinical result was more frequent when recanalization was achieved within 4.5 hours compared with patients with longer recanalization times (37/77 = 50% versus 10/50 = 20.0%; P = .001).
comparison with the first-generation Merci clot retriever devices (Concentric Medical, Mountain View, California) has been verified in 2 randomized studies. However, before December 2014, the only proved effective treatment for acute ischemic stroke was IV thrombolysis. This has now changed with the publication of 4 randomized studies: Multicenter Randomized Clinical Trial of Endovascular Treatment for Acute Ischemic Stroke in the Netherlands (MR CLEAN),20 Endovascular Treatment for Small Core and Anterior Circulation Proximal Occlusion With Emphasis on Minimizing CT to Recanalization Times (ESCAPE),21 Extending the Time for Thrombolysis in Emergency Neurologic Deficits–Intra-Articular (EXTEND IA),22 Solitaire With the Intention for Thrombectomy as Primary Endovascular Treatment Trial (SWIFT PRIME),23 and the Randomized Trial of Revascularization with the Solitaire FR Device Versus Best Medical Therapy in the Treatment of Acute Stroke Due to Anterior Circulation Large Vessel Occlusion Presenting within Eight Hours of Symptom Onset (REVASCAT).24 All of these studies compared endovascular treatment with IV thrombolysis alone, and all confirmed a benefit of the endovascular approach for certain patients.

Stent retriever devices were used in 82% and 86% of the interventional arms of MR CLEAN and ESCAPE, respectively, and in 100% of the interventional arms of EXTEND-IA, SWIFT PRIME, and REVASCAT. We used stent retrievers in all cases, resulting in a recanalization success of 77.7% (TICI 2b/3). This rate is within the range of ESCAPE (72.4%), EXTEND-IA (86.2%), and SWIFT PRIME (88.0%) and higher compared with the rather modest successful recanalization rate of MR CLEAN (58.7%).

The rate of good clinical outcomes varied widely in the recently published randomized trials, from 32.6% in MR CLEAN to 71.4% in EXTEND-IA. In our series, the clinical result after 3 months was available in a considerably high number of patients (95.4%), and an mRS of 0–2 was reached by 37.9% of them. Compared with the results of MR CLEAN, the higher percentage of successful recanalization certainly contributes to the better clinical outcome in our series; furthermore, the median time from stroke onset to groin puncture was shorter in our series (176 minutes) compared with MR CLEAN (260 minutes). However, the recanalization times were also shorter compared with ESCAPE (241 minutes) and EXTEND-IA, and both studies resulted in a higher percentage of patients with a favorable clinical outcome. We reason that comorbidities in our patient cohort ineligible for IV therapy contributed to the lower rate of good clinical outcomes compared with these studies.

Another parameter that should be discussed in this context is the lack of IV thrombolysis in our patient group. Intravenous thrombolytic treatment is frequently performed in patients with larger-artery occlusions before endovascular treatment by a “bridging” concept. However, the additional benefit from this regimen is unclear. Whereas the stent retriever series of Dávalos et al15 showed that patients had significantly better outcomes after IV thrombolysis and stent retriever thrombectomy compared with patients who were treated with stent retriever thrombectomy alone, this result could not be verified in the following Solitaire FR Thrombectomy for Acute Revascularisation trial (STAR)15 or other studies. Most patients in the interventional arm of MR CLEAN (87.1%), ESCAPE (72.7%), and REVASCAT (68.0%) and all of the patients in the interventional arm of EXTEND-IA and SWIFT PRIME received IV thrombolysis before endovascular treatment, whereas due to various contraindicating conditions, none of the patients in our study received IV bridging therapy. We cannot know whether additional IV thrombolysis would have changed the number of patients with a favorable clinical outcome in our series significantly, and we cannot exclude this factor contributing to the comparably low number of patients with good clinical results despite successful recanalization in our series (at least when compared with ESCAPE, EXTEND-IA and SWIFT PRIME). Certainly, further evaluation and discussion of this matter will be necessary.

The exciting results of MR CLEAN, ESCAPE, EXTEND-IA, SWIFT PRIME, and REVASCAT will potentially change the guidelines for acute stroke management regimens in the near future. Until then endovascular recanalization is limited to decisions on a case-by-case basis, and IV thrombolysis remains the recommended standard of care for all patients with ischemic stroke within a time window of 4.5 hours. Henceforth, careful selection of patients and an evidence-based definition of subgroups that most likely benefit from endovascular therapy will be necessary to allow the development of responsible decision algorithms.

Contraindications for IV thrombolysis are frequent and most commonly include anticoagulative abnormalities and a history of recent surgery. Furthermore, IV thrombolysis is avoided in patients with conceivable indications for acute stent placement (e.g., due to a dissection or stenosis) to avoid bleeding complications. According to most institutional guidelines, therapy for patients with contraindications for IV thrombolysis is limited to (noncausal) medical care, including the control of blood pressure and laboratory and vital parameters in a dedicated stroke care unit. Particularly for these patients, the chance of a (causal) endovascular treatment approach addressing the underlying pathology in the acute stroke phase may be of great benefit.

Certainly, the potential benefit of any medical therapy has to be balanced against a potential risk for adverse events. We found a periprocedural complication rate of 7.7% in our series, which is comparable with the results of the MR CLEAN and other trials and consisted of SAH, thrombus loss with subsequent infarction in previously not affected vessel territories, hemodynamically relevant dissections of extracranial arteries, and loss of devices.

Symptomatic intracranial hemorrhage after mechanical thrombectomy occurs in 4%–12% in larger case series and trials. Symptomatic hemorrhage was not increased in the interventional arm compared with the control group in MR CLEAN (7.7% versus 6.4%), ESCAPE (3.6% versus 2.7%), EXTEND-IA (0% for Solitaire, 6% for controls), SWIFT PRIME (0% versus 3.1%), and REVASCAT (1.9% in both groups). In our series, symptomatic hemorrhage occurred in 13.1% of patients; it occurred in a high percentage of patients who developed stroke under IV heparin (50%) but in <10% of patients who were under phenprocoumon at the time of stroke. However, due to the small
number of patients with IV heparin in our series, these results have to be interpreted carefully.

The present study has several limitations, and the results have to be interpreted with care. Due to its retrospective design, this multicenter study is prone to selection bias. There is no control group and no randomized patient selection. In addition, the patient cohort is not homogeneous for various reasons (eg, the included patients had acute strokes of different etiologies and with different vessel-occlusion patterns).

CONCLUSIONS

Our series indicates a potential benefit of stent retriever–based thrombectomy in patients with large-artery occlusions of the anterior circulation who are ineligible for IV thrombolysis. Successful and early recanalization was the most important factor for a good clinical outcome. Further prospective, controlled randomized studies will be necessary to prove the effectiveness of endovascular therapy for this specific patient group.
