Abstract: Three new furanocembranoids—briaviodiol F (1) and briaviotriols A (2) and B (3)—along with a known analogue, briaviodiol A (4), were obtained from a cultured-type octocoral *Briareum violaceum*. The structures of cembranoids 1–3 were elucidated by using spectroscopic methods. In vitro study demonstrated that compounds 2 and 4 exerted inhibition effects on inducible nitric oxide synthase (iNOS) release from RAW 264.7, a macrophage cell line that originated from a mouse monocyte macrophage, stimulated with lipopolysaccharides.

Keywords: *Briareum violaceum*; briaviodiol; briaviotriol; anti-inflammatory; iNOS
1. Introduction

*Briareum violaceum* (Quoy and Gaimard, 1883) is a soft coral of the family Briareidae [1,2], which has been found to contain cembrane-type diterpenoids in abundance [3–10]. Diterpenoids of this type have been reported to have complicated structures and possess a variety of bioactivities [3–10]. Recently, in our research into the chemical constituents and properties of a cultured octocoral *B. violaceum*, we have isolated three previously unreported furanocembranoids—briaviodiol F (1), and briaviodiols A (2) and B (3)—along with a known analogue, briaviodiol A (4) [9] (Figure 1). A pro-inflammatory suppression assay was employed to assess the activities of these isolated compounds against the release of inducible nitric oxide synthase (iNOS) from macrophage cells.

![Figure 1. Structures of briaviodiol F (1), briaviodiols A (2) and B (3), and briaviodiol A (4), and a picture of the octocoral *B. violaceum*.](image)

2. Results and Discussion

Briaviodiol F (1) was isolated as a colorless oil. Compound 1 displayed a pseudomolecular ion at *m/z* 403.20886 in the (+)-HRESIMS, which indicated its molecular formula was C21H32O6 + Na (calcd. for C21H32O6 + Na, 403.20911), suggesting six degrees of unsaturation. Additionally, IR absorptions at 3497 and 1754 cm⁻¹ indicated that 1 contained hydroxy and ester groups. As shown in Table 1, DEPT and $^{13}$C NMR spectra indicated that a suite of $^{13}$C resonances at $\delta_C$ 172.1 (C-17), 154.3 (C-1), 127.2 (C-15), 109.5 (C-2), and 9.2 (CH₃-16) were due to an $\alpha$-methyl-$\gamma$-butenolide moiety by comparison with the data of known cembranoids briaviodiol A (4) [9] and pachyclavulariolide F [6]. Moreover, resonances at $\delta_C$ 127.1 (C-4) and 135.1 (CH-5), and the olefinic proton at $\delta_H$ 5.30 (1H, dd, J = 8.0, 5.6 Hz, H-5) (Table 1), indicated an additional unsaturated functionality, suggesting the presence of a trisubstituted olefin. In the HSQC spectrum, an $sp^2$ carbon (δC 135.1) correlated with the methine proton (δH 5.30). This proton had $^3$J-correlations with H₂-6 (δH 1.93–1.99, 2H, m) in the $^1$H−$^1$H COSY spectrum, and had $^3$J-correlations with C-3 and C-18 in the HMBC spectrum (Table 1), further confirming the existence of a trisubstituted olefin. In light of the $^1$H and $^{13}$C NMR data, together with the degrees of unsaturation, 1 was determined as a tricyclic cembrane diterpene.

The $^1$H NMR coupling information in the COSY spectrum of 1 enabled the determination of the proton sequences between H-5/H₂-6/H₂-7/H-8/H₂-10/H₂-11 and H-8/H₂-19 (Table 1). The carbon skeleton of 1 was elucidated based on the key HMBC from H-3β, H-13, H-14, H₃-16 to C-1; H₂-3, H-14 to C-2; H₂-3, H₃-18 to C-4; H-10β, H-11α, H-13, H-14, H₂-20 to C-12; H-14, H₃-16 to C-15; and H₃-16 to C-17. The presence of a vinyl methyl group on C-4 was supported by HMBC from H₃-18 to C-3, C-4, C-5; H-3α (δH 2.78) to C-18 and H-5 to C-18. Furthermore, HMBC from OH-13 to C-13, C-14 and OH-14 to C-1, C-13, C-14 suggested the existence of hydroxyl groups at C-13 and C-14, respectively. Therefore, the methoxy group was on C-2, since the HMBC spectrum exhibited a correlation between the singlet at δH 3.39 (OMe) and C-2 (δC 109.5). Taking into account the molecular formula, the remaining oxygen atom must be part of the tetrahydrofuran ring located between C-9 and C-12.
Based on NOESY correlations and further information provided by MM2 forcefield calculations [11], the relative stereochemistry of 1 with the stable conformation is shown in Figure 2 (Supplementary Figures S1–10). When H-9 was α-oriented in 1, a correlation between H-9 and H3-19 was observed, suggesting that these protons were on the α-face, and H-8 was β-oriented. H-8 correlated with H-13, and the hydroxy proton OH-13 correlated with H3-20, suggesting that the hydroxy group at C-13 and the Me-20 at C-12 were α-oriented. H-14 exhibited a NOESY correlation with H-13, and no coupling constant was detected between H-13 and H-14 in the 1H NMR spectrum, implying that the dihedral angle located between H-13 and H-14 was about 90°, and the 14-hydroxy group was β-oriented. Correlations between H-5 and H-3, and H-14 and H-3 (δH 2.78) suggested that this proton is α, and the proton at δH 3.04 is 3β. Additionally, the proton signal of a methoxy group displayed NOESY correlations with both H-3α/β, which indicated that the methoxy group at C-2 was α-oriented. H3-18 was found to show a NOESY correlation with H-3β, but not with H-5, and H-5 was shown to be correlated with H-3α and H-14, which suggested an E-configuration of the C-4/5 double bond. The aforementioned results enabled establishment of the relative configuration of 1, and therefore its stereogenic carbons were assigned as 2R*,8R*,9S*,12R*,13S*, 14R*.

Briaviotriol A (2) was found to have the molecular formula C$_{21}$H$_{32}$O$_7$, as established by (+)-HRESIMS at $m/z$ 419.20377 (calc. for C$_{21}$H$_{32}$O$_7$ + Na, 419.20402). The $^1$H and $^{13}$C NMR spectra of 2 were very similar to those of 1. Comparison between the $^1$H and $^{13}$C NMR data of 2 (Table 2) and those of 1 suggested that the double bond is located between C-4 and C-18 in 2 instead of C-4 and C-15 in 1. HMBC from H$_2$-18 to C-3, C-4, C-5; and from H$_2$-3 and H-5 to C-18, corroborated the existence of an exocyclic double bond at C-4. In the HSQC spectrum, an oxymethine carbon ($\delta$C 69.1) correlated with the methine proton ($\delta$H 4.57), and this proton had $^3$J-$^3$J-correlations with H$_2$-6 ($\delta$H 1.81, 1H, m and 1.93, 1H, m) in the $^1$H–$^1$H COSY spectrum, demonstrating that a hydroxy group was attached to C-5.

| OH-13    | 2.42 br d (5.6)     |                 | H-13 |      |
| OH-14    | 2.29 br d (4.4)     |                 | H-14 |      |

The stereochemistry of 2 was established from the correlations observed in the NOESY spectrum (Figure 3 and Supplementary Figures S2–10). In addition, in the NOESY spectrum H-9 was correlated with H$_3$-19, which suggested that these protons were positioned on the same face and were assigned as $\alpha$ protons, as H-8 was $\beta$-oriented. H-13 correlated with H-8 and H-14, but no coupling between H-13 and H-14 was observed, demonstrating that the hydroxy groups at C-13 and C-14 were $\alpha$- and $\beta$-oriented, respectively. Correlations between an oxygen-bearing methyl ($\delta$H 3.26) and H-13 suggested that the C-2 methoxy group was situated on the $\beta$ face. Additionally, correlation between H-5 and H-8 supported a $\beta$-orientation of H-5. Based on the aforementioned results, the relative configurations of the stereogenic carbons of 2 were determined as 2S*, 5S*, 8R*, 9S*, 12R*, 13S*, 14R*. 

Table 2. $^1$H (400 MHz, CDCl$_3$) and $^{13}$C (100 MHz, CDCl$_3$) NMR, COSY, HMBC data for 2.
Compound 3 has a molecular formula C_{21}H_{32}O_{7} according to its (+)-HRESIMS m/z 419.20399 (calcd. for C_{21}H_{32}O_{8} + Na, 419.20402). The {^1}H and {^{13}}C NMR features of 3 resemble those of 1; comparison of the {^1}H and {^{13}}C NMR chemical shifts of the sp^2 methine proton and its respective carbon (δ_{H} 5.29, 1H, d, J = 8.4 Hz; δ_{C} 133.5, CH-5), and the sp^3 quaternary carbon (δ_{C} 131.0, C-4) of 3 (Table 3) with those of 1 (δ_{H} 5.30, 1H, dd, J = 8.0, 5.6 Hz; δ_{C} 135.1, CH-5; δ_{C} 127.1, C-4) (Table 1), as well as a NOESY correlation between H-5 and H_{2}-18, indicated the Z-configuration of the C-4/5 double bond (Figure 4 and Supplementary Figure S3–10). Furthermore, the HSQC spectrum showed that an oxymethine carbon (δ_{C} 68.7) was correlated with a methine proton (δ_{H} 4.86; H-6), and this proton exhibited ^{3}J-correlations with the olefinic proton H-5 (δ_{H} 5.29) and H_{2}-7 (δ_{H} 1.34, 1H, m; 1.80, 1H, m) in the COSY spectrum, which confirmed a hydroxy group at C-6. As H-6 showed a NOESY correlation with H-3β, this suggested that the C-6 hydroxy group was α-oriented. Based on a NOESY experiment (Figure 4 and Supplementary Figures S3–10), 3 was identified to have the stereogenic centers 2R*,6S*,8R*,9S*,12R*,13S*,14R*. Since 3 has never been previously reported, it was named briaviotriol B.

Table 3. {^1}H (400 MHz, CDCl_{3}) and {^{13}}C (100 MHz, CDCl_{3}) NMR, and COSY, HMBC data for 3.

Compound 4 was identified as briaviodiol A (Figure 1), by comparison of its $^1$H and $^{13}$C NMR data with those in the literature [9]. Using an in vitro pro-inflammatory suppression assay, the effects of 1–4 on the release of iNOS protein from lipopolysaccharide (LPS)-stimulated RAW 264.7 macrophage cells were assessed. First, alamar blue cell viability assessment revealed that 1–4 did not have significant cytotoxic effects in RAW 264.7 cells. The results of the in vitro pro-inflammatory suppression assay showed that 2 and 4 at 10 μM suppressed the release of iNOS to 67.7 and 61.9%, respectively, when compared with results of the cells stimulated with only LPS (Table 4). Compound 1 showed no suppression effect on iNOS release.

Table 4. Effects of 1–4 on LPS-induced pro-inflammatory iNOS release in RAW 264.7 cells at a concentration of 10 μM. The data presented are the relative intensity normalized to the LPS-stimulated group. Compounds 2 and 4 were found to have the higher inhibition effects on LPS-induced iNOS expression in macrophages expression.

|   | iNOS Expression (% of LPS) |
|---|---------------------------|
| LPS | 100.0 ± 7.0               |
| 1   | 109.0 ± 19.2              |
| 2   | 67.7 ± 2.4                |
| 3   | 79.5 ± 9.4                |
| 4   | 61.9 ± 7.3                |

3. Experimental Section

3.1. General Experimental Procedures

The JEOL NMR spectrometer (model ECZ400S, Tokyo, Japan) was used to record the spectra with the solvent peak of CHCl$_3$ ($\delta_{H}$ 7.26 ppm) and CDCl$_3$ ($\delta_{C}$ 77.1 ppm) as internal references for $^1$H NMR and $^{13}$C NMR, respectively. ESIMS and HRESIMS were obtained from the Bruker mass spectrometer with 7 Tesla magnets (model: Solarix FTMS system) (Bremen, Germany). Column chromatography, IR spectra and optical rotation were performed according to our earlier research [10].
3.2. Animal Material

Specimens of *B. violaceum* used for this study were collected in December 2016 from the cultivation tank (capacity = 270 tons) at the National Museum of Marine Biology and Aquarium (NMMBA) in Southern Taiwan. For its identification, this coral species was compared to reliable sources published earlier [1,2]. A voucher specimen was deposited in the NMMBA (voucher no.: NMMBA‐CSC‐005).

3.3. Extraction and Isolation

Sliced bodies (wet/dry weight = 358.7/144.5 g) of the coral specimen were prepared and extracted with a 1:1 mixture of MeOH and CH$_2$Cl$_2$ to give 17.2 g of crude extract which was partitioned between EtOAc and H$_2$O to obtain 6.3 g of the EtOAc extract. The EtOAc extract was then applied onto a silica gel column and eluted with gradients of *n*-hexane/EtOAc (100% *n*-hexane – 100% EtOAc, stepwise), to furnish 14 fractions (fractions: A – N). Fraction G was further chromatographed on a silica gel column and eluted with gradients of *n*-hexane/Me$_2$CO (20:1 – 100% Me$_2$CO, stepwise) to afford 11 subfractions (fractions: G1 – G11). Fraction G4 was applied onto a silica gel column and eluted with gradients of *n*-hexane and Me$_2$CO (20:1 – 100% Me$_2$CO, stepwise) to give 12 subfractions (fractions: G4A – G4L). Afterwards, fraction G4E was then separated by normal-phase HPLC (NP‐HPLC) using a mixture of *n*-hexane and Me$_2$CO (5:1) as solvent to obtain 5 subfractions (fractions: G4E1 – G4E5). Then, fraction G4E1 was separated by NP‐HPLC using a mixture of CH$_2$Cl$_2$ and Me$_2$CO (with volume: volume = 80:1; at a flow rate = 3.0 mL/min) to afford 1 (62.7 mg). Fraction G4H was separated by NP‐HPLC using a mixture of *n*-hexane and Me$_2$CO (with volume: volume = 4:1; at a flow rate = 2.0 mL/min) to afford 4 (17.0 mg). Fraction G4J was repurified by NP‐HPLC using a mixture of *n*-hexane and Me$_2$CO (with volume: volume = 3:1; at a flow rate = 2.0 mL/min) to afford 3 (0.9 mg). Fraction G8 was separated by NP‐HPLC using a mixture of *n*-hexane and Me$_2$CO (3:1) to obtain 6 subfractions G8A – G8F. Fraction G8F was repurified by reverse-phase HPLC (RP‐HPLC) using a mixture of MeCN and H$_2$O (with volume: volume = 1:1; at a flow rate = 1.0 mL/min) to yield 2 (1.2 mg).

Briaviodiol F (1): Colorless oil; [α]$_D^{21}$ +223 (c 1.48, CHCl$_3$); IR (neat) $\nu_{max}$ 3497, 1754 cm$^{-1}$; $^1$H and $^{13}$C NMR data (see Table 1); ESIMS: $m/z$ 403 [M + Na]$^+$; HRESIMS: $m/z$ 403.20868 (calcd. for C$_{21}$H$_{32}$O$_6$ + Na, 403.20911).

Briaviotriol A (2): Colorless oil; [α]$_D^{22}$ −68 (c 0.06, CHCl$_3$); IR (neat) $\nu_{max}$ 3424, 1749 cm$^{-1}$; $^1$H and $^{13}$C NMR data (see Table 2); ESIMS: $m/z$ 419 [M + Na]$^+$; HRESIMS: $m/z$ 419.20377 (calcd. for C$_{21}$H$_{32}$O$_7$ + Na, 419.20402).

Briaviotriol B (3): Colorless oil; [α]$_D^{23}$ −39 (c 0.04, CHCl$_3$); IR (neat) $\nu_{max}$ 3424, 1749 cm$^{-1}$; $^1$H and $^{13}$C NMR data (see Table 3); ESIMS: $m/z$ 419 [M + Na]$^+$; HRESIMS: $m/z$ 419.20399 (calcd. for C$_{21}$H$_{32}$O$_7$ + Na, 419.20402).

Briaviodiol A (4): Colorless crystal; [α]$_D^{21}$ −52 (c 0.85, CHCl$_3$) (Reference [9]; [α]$_D^{23}$ −31 (c 0.14, CHCl$_3$)); IR (neat) $\nu_{max}$ 3467, 1747 cm$^{-1}$; $^1$H and $^{13}$C NMR data were found to be in absolute agreement with previous study [9]; ESIMS: $m/z$ 403 [M + Na]$^+$.

3.4. Molecular Mechanics Calculations

The molecular models were generated by implementing the MM2 force field [11] in ChemBio 3D Ultra software (ver. 12.0) which was created by CambridgeSoft (PerkinElmer, Cambridge, MA, USA).

3.5. In Vitro Anti-Inflammatory Assay

The pro-inflammatory suppression assay was performed using a murine macrophage cell line, RAW 264.7, which was purchased from the American Type Culture Collection (ATCC cell line no. TIB-71; Manassas, VA, USA). Untreated or LPS-induced RAW 264.7 cells were used to determine the anti-inflammatory activities of cembranoids 1–4 by assessing the inhibition of pro-inflammatory iNOS release from macrophage cells. The iNOS protein levels were measured by using western blotting.
Mar. Drugs 2019, 17, 214

analysis [12–14]. Briefly, in the control group, macrophages were incubated in compound-free medium with LPS (10 µM) alone for 16 h; and in the cembranoid-treated groups, the cells were pre-treated with cembranoids 1–4 (10 µM) for 10 min followed by an LPS challenge for 16 h. After the incubation, cell lysates were collected, and equal amounts of the total protein samples were subjected to western blot analysis. The immunoreactivities were calculated based on the optical densities of the corresponding iNOS bands of each group on the membrane, and the cells with LPS treatment alone were set to be 100%. Viability of macrophage cells of different groups was determined after treatment with alamar blue (Invitrogen, Carlsbad, CA, USA), a chemical of tetrazolium dye that is reduced by living cells to a fluorescent substance. The assay has been shown to have accurate measurement in determining the survival of RAW 264.7 cells [15,16], which is based on a mechanism similar to that of an assay using 3-(4,5-dimethylthiazol-2-yl)-2,5- diphenyltetrazolium bromide. Data analyses were firstly performed using one-way analysis of variance (ANOVA), and further analyzed by the Student-Newman-Keuls post hoc test for multiple comparison. All the data with a p-value of < 0.05 were considered as a significant difference.

4. Conclusions

*B. violaceum* has been demonstrated to have a wide structural diversity of interesting diterpenoids that possess various pharmacological properties [17]. This specimen was encrusted on different species of scleractinian hard corals in the Indo-Pacific coral reef system [18]. In our continued study of *B. violaceum*, three previously unreported furanocembranoids 1–3 were isolated, together with the previously described briaviodiol A (4). In the present study, the anti-inflammatory activities of 1–4 were assessed using inhibition of pro-inflammatory iNOS release from macrophages. The results indicated that briaviotriol A (2) and briaviodiol A (4) showed the most potent suppressive effects on iNOS release.

**Supplementary Materials:** The Supplementary Materials are available online at http://www.mdpi.com/1660-3397/17/4/214/s1. ESIMS, HRESIMS, IR, 1D (1H NMR, 13C NMR, and DEPT spectra), and 2D (COSY, HSQC, HMBC, and NOESY) spectra of new compounds 1–3 and 1H and 13C NMR spectra of 4.

**Author Contributions:** P.-C.H., W.-S.L., Z.-H.W., and P.-J.S. designed the whole experiment and contributed to manuscript preparation. B.-R.P., Y.-C.C., L.-S.F., G.-Q.L., and T.-L.H. analyzed the data and performed data acquisition.

**Funding:** This research was supported by grants from the National Museum of Marine Biology and Aquarium; the National Dong Hwa University; and the Ministry of Science and Technology, Taiwan (Grant Nos: MOST 104-2320-B-291-001-MY3 and 107-2320-B-291-001-MY3) awarded to Ping-Jyun Sung.

**Conflicts of Interest:** The authors declare no conflicts of interest.
