The role of electron-phonon scattering in finite-temperature anomalous Hall effect is still poorly understood. In this work, we present a Boltzmann theory for the side-jump contribution from electron-phonon scattering, which is derived from the microscopic quantum mechanical theory. We show that the resulting phonon side-jump conductivity generally approaches different limiting values in the high and low temperature limits, and hence can exhibit strong temperature dependence in the intermediate temperature regime. Our theory is amenable to ab initio treatment, which makes quantitative comparison between theoretical and experimental results possible.

I. INTRODUCTION

Electron-phonon scattering plays a key role in electronic transport in crystalline solids [1, 2]. For longitudinal transport, electron-phonon scattering limits the intrinsic mobility, and its effect can now be well evaluated via a combination of the first-principles band structure calculation and semiclassical Boltzmann approach [3–10]. However, its role in the anomalous Hall transport is much more subtle [11–18], and a clear understanding has yet to be achieved.

Theoretical study of the anomalous Hall transport has been mostly performed with static impurities [12]. In the weak scattering regime, anomalous Hall conductivity is known to have three important contributions arising from different mechanisms in the semiclassical picture [19–20]: intrinsic contribution from Berry curvatures in band structures [21, 22], side jump from electron coordinate shift during scattering [23–24], and skew scattering from the asymmetric part of the scattering rate [25–26]. Particularly, side jump is a very peculiar contribution in that although it results from scattering, its value is found to be independent of the impurity concentration for static impurity scattering [12, 23–25].

Will phonon scattering be any different? Typically, the phonon energy scale (k_B T) is much less than the Fermi energy e_F, so the energy transfer in phonon scattering would be negligible. It seems that the phonon side jump contribution should be similar to that of static impurities, and hence it should be insensitive to temperature (T) [23–29, 30]. This speculation has gained support from experiments performed at elevated temperatures where the longitudinal resistivity shows linear in T dependence [31–33]. Recently, researchers do realize that the side-jump from phonon and impurity scattering can be different, thereby the change of their relative importance with temperature can lead to T-dependent behavior [12, 34]. However, the T-independence of the phonon side-jump contribution alone has not been doubted.

In a very recent work [35], it is realized that the phonon side jump contribution can indeed be T-dependent. The key ingredient is the T-dependent phonon occupation number, which makes the average momentum transfer, i.e., the effective range, of electron-phonon scattering T-dependent. By analogy with the recently revealed sensitivity of the anomalous Hall conductivity to the scattering range of static random impurities [36], one can understand qualitatively the T-dependence of phonon side jump.

However, we do not yet have a theory of phonon side jump with quantitative predictive power, accounting for the dynamical and inelastic nature of electron-phonon scattering. Here, we develop such a theory within the semiclassical Boltzmann framework. Surely, one may choose to construct a theory on a more fundamental level, with a fully quantum field theoretical treatment, and there were indeed a few attempts in the past [37, 38]. Unfortunately, due to the complexity in modeling phonon scattering, such transport theories are extremely complicated, lacking physical transparency, and too difficult to be combined with ab initio calculations for real materials. In comparison, the semiclassical theory presented here enjoys the advantages of being physically intuitive and easily implementable with ab initio calculations. As an application of this theory, we show that the phonon side jump conductivity generally saturates to two different values in low and high temperature limits, and the strong T-dependence naturally appears in the temperature regime in-between.

Our paper is organized as follows. In Sec. II we review the semiclassical theory for side jump from impurity scattering, and propose the new theory for phonon-induced side-jump in a heuristic way. In Sec. III, we present a general argument for the T-dependence of phonon side jump conductivity. This T-dependence is explicitly demonstrated in Sec. IV, by applying our theory to study the concrete massive Dirac model. Finally, in Sec. V, we discuss the possible experimental scheme to confirm our result and conclude this work. The detailed derivation of our theory is presented in the Appendix.
II. BOLTZMANN THEORY FOR PHONON SIDE JUMP

We start by reviewing the theory for side jump induced by impurity scattering. The semiclassical nonequilibrium distribution function \( f \) for electron wave-packets in phase space is governed by the Boltzmann equation:

\[
\left( \partial_t + \mathbf{v} \cdot \nabla + \mathbf{k} \cdot \nabla \right) f = I_{\text{coll}}[f].
\] (1)

With a uniform dc electric field and in the steady state, the linearized equation takes the form of (set \( \epsilon = \hbar = 1 \))

\[
E \cdot \mathbf{v}^0 \partial_{\ell \ell} f^0_\ell = - \sum_{\ell'} [w_{\ell \ell'} f_{\ell'} (1 - f_{\ell'}) - (\ell \leftrightarrow \ell')] \] (2a)

where the added subscript \( \ell \equiv n \mathbf{k} \) labels the Bloch state, \( \mathbf{v}^0_\ell = \partial_{\mathbf{k} \ell} \) is the band velocity, \( f^0_\ell \) is the equilibrium Fermi-Dirac distribution function, the collision term \( I_{\text{coll}}[f] \) on the right hand side is explicitly written out with a scattering-out term \( (\ell \rightarrow \ell') \) and a scattering-in term \( (\ell' \rightarrow \ell) \), and \( w \) is the corresponding scattering rate. We may write \( f_\ell = f^0_\ell + \delta f_\ell = f^0_\ell + (-\partial_{\ell \ell} f^0_\ell) g_\ell \), where the second equality indicates the fact that the nonequilibrium deviation should be around the Fermi surface and \( g_\ell \) is a smooth function of energy and momentum. In the absence of side jump, using the principle of detailed balance, namely, \( w_{\ell \ell'} f^0_{\ell'} = w_{\ell' \ell} f^0_{\ell} \) and keeping terms to linear order in \( E \), one can show that Eq. (2a) can be put into the following form for \( g_\ell \):

\[
E \cdot \mathbf{v}^0_\ell = \sum_{\ell'} \frac{1 - f^0_{\ell'}}{1 - f^0_\ell} w_{\ell' \ell} (g_{\ell'} - g_\ell). \] (2b)

Here, we emphasize that Eqs. (2a) and (2b) are valid for both static (impurity) and dynamical (phonon) disorder. For static impurities, the factor \( (1 - f^0_\ell)/(1 - f^0_{\ell'}) \) in Eq. (2b) (which may be called the Pauli factor) becomes unity, and the result reduces to the familiar one in textbooks.

Side jump refers to the coordinate shift of the electron wave-packet during scattering, for which Sinitsyn et al. have derived a general expression [24]:

\[
\delta r_{\ell \ell'} = -\mathbf{A}_{\ell'} - \partial_{\ell \ell'} \arg V_{\ell \ell'}, \]

where \( \mathbf{A}_{\ell} = i(\mathbf{u}_{\ell} \partial_{\mathbf{k} \ell} \mathbf{u}_{\ell}) \) is the Berry connection, \( |\mathbf{u}_{\ell} \rangle \) is the periodic part of the Bloch state, and \( V_{\ell \ell'} \) is the scattering matrix element.

Due to this coordinate shift, the \( E \) field does a nonzero work in scattering, which has to be accounted for in energy conservation [19]. For static impurity scattering, one then has \( \epsilon_{\ell'} = \epsilon_\ell + E \cdot \delta r_{\ell \ell'} \). Consequently, the equilibrium distribution no longer annihilate the collision term, because \( f^0_\ell - f^0_{\ell'} \approx -\partial_{\ell \ell'} f^0_\ell E \cdot \delta r_{\ell \ell'} \), and from the Boltzmann equation, this leads to an additional (anomalous) correction to the distribution function: \( \delta f^0_\ell = \left( -\partial_{\ell \ell'} f^0_\ell \right) g^0_\ell \), satisfying

\[
E \cdot \sum_{\ell'} w_{\ell' \ell} \delta r_{\ell' \ell} = - \sum_{\ell'} w_{\ell' \ell} (g^0_{\ell'} - g^0_\ell). \] (4)

Thus, the out-of-equilibrium part of the distribution is

\[
\delta f_\ell = \delta f^0_\ell + \delta f^\rho_\ell = \left( -\partial_{\ell \ell'} f^0_\ell \right) \left( g^0_\ell + g^0_{\ell'} \right), \] (5)

where the terms with superscript \( n \) refer to the “normal” contribution, satisfying Eq. (2b) without the side jump effect. Meanwhile, the side jump also corrects the electron velocity, which becomes

\[
\mathbf{v}_\ell = \mathbf{v}^0_\ell + \mathbf{v}^{bc}_\ell + \mathbf{v}^3_\ell. \] (6)

Here, \( \mathbf{v}^{bc}_\ell = \mathbf{A}_\ell \times \mathbf{E} \) is the anomalous velocity induced by Berry curvature \( \mathbf{A}_\ell = \partial_{\mathbf{k}} \times \mathbf{A}_\ell \), and

\[
\mathbf{v}^3_\ell = \sum_{\ell'} w_{\ell' \ell} \delta r_{\ell' \ell} \] (7)

is called the side jump velocity. Applying the \( E \) field in the \( x \) direction, then the intrinsic anomalous Hall current is given by \( j_{\text{AH}}^{\text{in}} = \sum_{\ell} f^0_\ell \left( \mathbf{v}^{bc}_\ell \right)_y \). The side jump induced Hall current, which is the focus of this paper, contains two terms to linear order in \( E \):

\[
j_{\text{AH}} = j_{\text{AH}}^{(1)} + j_{\text{AH}}^{(2)} = \sum_{\ell} \delta f^0_\ell \left( \mathbf{v}^{bc}_\ell \right)_y + \sum_{\ell} \delta f^\rho_\ell \left( \mathbf{v}^3_\ell \right)_y. \] (8)

Note that counting the order in relaxation time \( \tau \), \( \delta f^{\rho}_\ell \sim \tau \), \( \delta f^{\rho}_\ell \sim \tau^2 \), \( v^3_\ell \sim \tau^{-1} \), and \( v^{bc}_\ell \sim 1 \), so both terms in \( j_{\text{AH}} \) are on the order of \( \tau^0 \). For static impurities, the side jump contribution is independent of the impurity density as well as the scattering potential strength.

The above semiclassical theory was shown to be consistent with fully quantum mechanical treatment for static impurities [20]. Particularly, the side jump velocity in Eq. (7) was found to correspond to the scattering-induced band-off-diagonal elements of the out-of-equilibrium density matrix [21, 39, 40].

Now let’s turn to phonon scattering. In the following, we present a heuristic argument for the theory. First of all, we note that Eqs. (2a) and (4) apply for dynamical disorder like phonons as well. Like before, the side jump leads to an additional work done by the \( E \) field, modifying the relation between \( \epsilon_{\ell'} \) and \( \epsilon_\ell \), with

\[
\tilde{\epsilon}_{\ell'} = \epsilon_\ell + E \cdot \delta r_{\ell \ell'} \pm \omega_q. \] (9)

where the last term indicates the absorption or emission of a phonon with mode label \( q \). Then the linearized Boltzmann equation becomes (details in Appendix A)

\[
E \cdot \mathbf{v}^0_\ell = \sum_{\ell'} \frac{1 - f^0_\ell}{1 - f^0_{\ell'}} w_{\ell' \ell} (g_{\ell'} - g_\ell + E \cdot \delta r_{\ell \ell'}) \] (10)

where \( \epsilon_{\ell'} = \epsilon_\ell \pm \omega_q \). Subtracting Eq. (2b) from Eq. (10) shows that the anomalous correction to the distribution due to side jump satisfies the equation

\[
E \cdot \sum_{\ell'} \frac{1 - f^0_\ell}{1 - f^0_{\ell'}} w_{\ell' \ell} \delta r_{\ell' \ell} = - \sum_{\ell'} \frac{1 - f^0_\ell}{1 - f^0_{\ell'}} w_{\ell' \ell} (g^0_{\ell'} - g^0_\ell). \] (11)
Comparing Eq. (11) with Eq. (4) suggests that the proper definition for the phonon side jump velocity should be

$$w_{\ell}^n = \sum_{\ell'} \frac{1}{2} - f_\ell^0 \frac{1}{2} w_{\ell \ell'} \delta r_{\ell \ell'} .$$  (12)

The above three equations are the main results of this paper. Here, the main difference between Eqs. (11, 12) and Eqs. (4,7) is the appearance of the Pauli factor, which, as we have discussed before, reflects the dynamical character of phonon scattering. For static impurity scattering, the Pauli factor becomes unity, and the theory correctly describes the situation. Here, the main difference between Eqs. (11, 12) and with Eq. (12) and with $g^2 \sigma$ solved from Eq. (11), the side jump current will still be calculated with Eq. (8). This completes our semiclassical theory for phonon side jump.

This theory, albeit seemingly simple and intuitive, is in fact nontrivial. Its justification requires tedious derivation from microscopic theories of coupled electron-phonon system. We have demonstrated that the theory can be derived from two different fundamental approaches: the density matrix equation of motion approach [41] and the Lyo-Holstein’s transport theory [38, 42]. The details are relegated to Appendices C and D.

### III. TEMPERATURE DEPENDENCE OF PHONON SIDE JUMP

As we have mentioned at the beginning, for $k_B T \ll \epsilon_F$, the common belief is that the phonon side jump Hall conductivity $\sigma_{AH}^{sj}$ should be independent of the strength of disorder scattering (so its value remains the same even if the disorder density approaches zero), and hence it should have little $T$ dependence. As an application of our theory, we shall see that this naive conclusion is generally incorrect in the case where side jump arises from spin-orbit-coupled Bloch electrons scattered off phonons.

Consider the low-$T$ limit, which is specified by $T \ll T_D$, where $T_D$ is the Debye temperature (Note that in this discussion, $\epsilon_F$ is always assumed to be the largest energy scale). For such case, the scattering is dominated by long wavelength acoustic phonons, which is short ranged in momentum space. Hence, the coordinate shift reduces to $\delta r_{\ell \ell'} \approx \Omega_{\ell} \times (\mathbf{k'} - \mathbf{k})$. From Eq. (11), we find that $g^2 = \mathbf{E} \cdot (\Omega_{\ell} \times \mathbf{k})$, whose contribution to the Hall conductivity (corresponding to $j_{AH}^{\sigma_1(2)}$) is $\sigma_{AH}^{\sigma_1(2)} = -\sum_\ell (\Omega_{\ell} \times \mathbf{k}) \cdot \partial_{\mathbf{k}_y} f_\ell^0$. Meanwhile, straightforward calculation of $j_{AH}^{\sigma_1(1)}$ yields $\sigma_{AH}^{\sigma_1(1)} = \sum_\ell (\Omega_{\ell} \times \mathbf{k}) \cdot \partial_{\mathbf{k}_x} f_\ell^0$.

Thus, the phonon side jump Hall conductivity in the low-$T$ limit can be put into a compact form of

$$\sigma_{AH}^{\sigma_1} = -\sum_\ell \left[ (\Omega_{\ell} \times \mathbf{k}) \times \partial_{\mathbf{k}_y} f_\ell^0 \right]_z .$$  (13)

For two-dimensional systems, the Berry curvature has only $z$-component $\Omega_{\ell} \times \hat{z}$, so the above result can be further simplified as

$$\sigma_{AH}^{\sigma_1} = \sum_\ell \Omega_{\ell} \cdot \mathbf{k} \cdot \partial_{\mathbf{k}_y} f_\ell^0 .$$  (14)

In the high-$T$ limit with $T \gg T_D$, we find that the major $T$ dependence comes from the scattering rate, which can be approximated as

$$w_{\ell \ell'} \approx 4\pi |\langle \mathbf{u}_{\ell} | \mathbf{u}_{\ell'} \rangle|^2 |V_{k'k}^0|^2 \frac{k_B T}{\omega_q} \delta (\epsilon_k - \epsilon_{k'}).$$  (15)

Here, we have written $\mathbf{V}_{\ell \ell'} = V_{k'k}^0 (\mathbf{u}_{\ell} | \mathbf{u}_{\ell'} \rangle$, with $V_{k'k}^0$ the plane-wave part of the electron-phonon scattering matrix element, and we have used the relation that $N_q = (N_q + 1) \approx k_B T / \omega_q$ in the high-$T$ limit, where $N_q$ is the Bose-Einstein distribution for the phonon mode $q$. Hence in the high-$T$ limit, we have $g^2 \sim T^{-1}$, $v^2 \sim T$, $g^2 \sim T^0$, and thus $\sigma_{AH}^{\sigma_1}$ should saturate to a $T$-independent constant value. Although we cannot write down a compact analytical expression for this limiting value (because of the complicated model-dependent interband scattering processes), it is clear that this value should generally be different from the low-$T$ limit value in Eq. (14). This analysis demonstrates that the phonon side jump conductivity $\sigma_{AH}^{\sigma_1}$ approaches different values in the low-$T$ and high-$T$ limits, therefore pronounced $T$ dependence must exist in the intermediate range when the two limiting values differ by a significant amount.

### IV. APPLICATION TO MASSIVE DIRAC MODEL

In this section, we illustrate the above points by a concrete model calculation using our theory. We take the two-dimensional massive Dirac model

$$\mathcal{H}_0 = v (k_x \sigma_x + k_y \sigma_y) + \Delta \sigma_z ,$$  (16)

which is considered as the minimal model for studying anomalous Hall effect. Here, $v$ and $\Delta$ are model parameters, and the $\sigma$’s are the Pauli matrices representing the two Dirac bands. Recalling that we work under the condition $k_B T \ll \epsilon_F$, hence, to proceed analytically, we neglect the phonon energy in the scattering, such that $k = k'$ for the two electronic states before and after scattering [4]. We consider the metallic regime $\epsilon_F > \Delta$ with low carrier density such that the Fermi surface is much smaller than the size of Brillouin zone. Thus the Umklapp process does not occur. We assume the scattering is dominated by acoustic phonons, and the electron-phonon interaction is treated perturbatively.

Using the density matrix equation of motion approach, we find that the side jump Hall conductivity $\sigma_{AH}^{\sigma_1}$ becomes

$$\sigma_{AH}^{\sigma_1} = \sum_\ell (\Omega_{\ell} \times \mathbf{k}) \cdot \partial_{\mathbf{k}_x} f_\ell^0 .$$ (17)

This can be further simplified in the low-$T$ limit to

$$\sigma_{AH}^{\sigma_1} = k_B T \sum_\ell \Omega_{\ell} \cdot \mathbf{k} \cdot \partial_{\mathbf{k}_x} f_\ell^0 .$$ (18)

In the high-$T$ limit with $T \gg T_D$, we find that the major $T$ dependence comes from the scattering rate, which can be approximated as

$$w_{\ell \ell'} \approx 4\pi |\langle \mathbf{u}_{\ell} | \mathbf{u}_{\ell'} \rangle|^2 |V_{k'k}^0|^2 \frac{k_B T}{\omega_q} \delta (\epsilon_k - \epsilon_{k'}).$$ (19)

Here, we have written $\mathbf{V}_{\ell \ell'} = V_{k'k}^0 (\mathbf{u}_{\ell} | \mathbf{u}_{\ell'} \rangle$, with $V_{k'k}^0$ the plane-wave part of the electron-phonon scattering matrix element, and we have used the relation that $N_q = (N_q + 1) \approx k_B T / \omega_q$ in the high-$T$ limit, where $N_q$ is the Bose-Einstein distribution for the phonon mode $q$. Hence in the high-$T$ limit, we have $g^2 \sim T^{-1}$, $v^2 \sim T$, $g^2 \sim T^0$, and thus $\sigma_{AH}^{\sigma_1}$ should saturate to a $T$-independent constant value. Although we cannot write down a compact analytical expression for this limiting value (because of the complicated model-dependent interband scattering processes), it is clear that this value should generally be different from the low-$T$ limit value in Eq. (14). This analysis demonstrates that the phonon side jump conductivity $\sigma_{AH}^{\sigma_1}$ approaches different values in the low-$T$ and high-$T$ limits, therefore pronounced $T$ dependence must exist in the intermediate range when the two limiting values differ by a significant amount.
coupling can be described by the deformation potentials (details in Appendix B). The coordinate shift for this model can be found as

\[ (\delta r^\prime_{k^\prime k})_{y} = -\frac{\Delta \epsilon^2}{2(\Delta^2 + (\epsilon k)^2)^{3/2}} \left( \frac{k^\prime_{x} - k_{x}}{|\langle u_{k^\prime} | u_{k} \rangle|^2} \right), \]  

(17)

And straightforward calculation (see Appendix B for details) based on our theory leads to

\[ \sigma_{AH}^{sj} = \frac{1}{4\pi} \frac{\Delta}{\epsilon_F} \left[ 1 - \left( \frac{\Delta}{\epsilon_F} \right)^2 \right] \mathcal{R}(\epsilon_F, T), \]  

(18)

where the temperature dependence is dumped into the factor \( \mathcal{R} \) defined as \( \mathcal{R} \equiv \tau^{tr}/\tau^{sj} \), where \( \tau^{tr} \) is the transport relaxation time with

\[ (\tau^{tr})^{-1} = \sum_{k^\prime} \frac{1}{1 - \frac{f_{k^\prime}^{0}}{f_{k}^{0}}} w_{k^\prime k} \left( 1 - \cos \phi_{kk^\prime} \right), \]  

(19)

\( \tau^{sj} \) is defined as

\[ (\tau^{sj})^{-1} = \sum_{k^\prime} \frac{1}{1 - \frac{f_{k^\prime}^{0}}{f_{k}^{0}}} \frac{w_{k^\prime k}}{|\langle u_{k^\prime} | u_{k} \rangle|^2} \left( 1 - \cos \phi_{kk^\prime} \right), \]  

(20)

and \( \phi_{kk^\prime} \) is the angle between \( k \) and \( k^\prime \). In the low-\( T \) and high-\( T \) limits, we have respectively

\[ \mathcal{R} \to 1 \quad \text{and} \quad \mathcal{R} \to 4[1 + (\Delta/\epsilon_F) \left( \Delta/\epsilon_F \right)^2]^{-1}. \]  

(21)

This demonstrates clearly that the phonon side jump contribution approaches different values in the low-\( T \) and high-\( T \) limits. This behavior is illustrated in Fig. 1 where the \( T \)-dependence in the intermediate regime is obtained by assuming isotropic Debye spectrum \( \omega_q = c_s q \) (\( c_s \) is the sound velocity). The \( T \)-dependence of the phonon side-jump contribution becomes apparent when \( T < T_{BG}/2 \). Note that in the same regime, one can show that the phonon-limited longitudinal resistivity also departs from the linear-\( T \) scaling (see the inset of Fig. 1). Here \( T_{BG} = 2\hbar c_s k_{F}/k_{B} \) is the Bloch-Gruneisen temperature, which marks the lower boundary of the high-\( T \) equipartition regime (\( \rho \sim T \)) in two-dimensional metallic systems [9].

V. DISCUSSION AND CONCLUSION

We discuss the possible experimental scheme to confirm our result. The \( d \)-band ferromagnetic transition metals such as Fe and Co offer suitable platforms, because their band splittings are much larger than room temperature, and the Curie temperatures are much higher than \( T_D \). It follows that the intrinsic Berry-curvature contribution to the anomalous Hall conductivity should be \( T \)-insensitive up to room temperature. In order to observe the electron-phonon dominated behavior at lower temperatures (where \( \rho \) deviates from the linear-in-\( T \) scaling), one needs to work with high-purity samples (the resistance ratio should be at least 100), which are experimentally accessible [2]. The skew scattering contribution due to non-Gaussian impurity correlations should be first subtracted from the data. This can be done by using the recently developed thin-film approach [15, 43]. In this approach one can limit the scattering of electrons to two main sources — the interface roughness and phonons, and achieve independent control of each one by tuning the film thickness and the temperature [43]. The aforementioned skew scattering Hall conductivity in this case is given by \( \alpha_{0}\rho_{0}/\rho^2 \), where \( \rho_{0} \) is the residual resistivity, and \( \alpha_{0} \) is a system-specific parameter independent of film thickness that can be determined by tuning film thickness in the low-\( T \) regime [15]. After subtracting the skew scattering contribution, one can verify the \( T \)-dependence of the side-jump conductivity predicted here. Quantitatively, one can further subtract the \( T \)-insensitive intrinsic contribution obtained from \textit{ab initio} method [22], and then compare the remaining to the phonon side-jump Hall conductivity yielded by the \textit{ab initio} Boltzmann approach based on our result.

In conclusion, we have proposed a semiclassical Boltzmann theory for the phonon side jump contribution in the anomalous Hall effect. This intuitive theory has been derived from microscopic quantum mechanical transport theories of coupled electron-phonon systems. We demonstrate that the phonon side jump anomalous Hall conductivity can generally be temperature-dependent, which disproves the previous common belief that this contribution is \( T \)-independent. The possible experimental scheme to confirm our result has been discussed. The proposed Boltzmann formalism can be easily implementable with \textit{ab initio} calculations, making quantitative comparison between theoretical and experimental results possible.

Appendix A: Heuristic argument for the side jump in the Bloch-Boltzmann equation

In the presence of a dc weak uniform electric field $E$ and weak static disorder, the conventional Boltzmann equation for charge carriers (charge $e$) in nonequilibrium steady state reads $^{1}$

$$eE \cdot v_\ell^0 \left( - \frac{\partial f_\ell^0}{\partial \epsilon_\ell} \right) = \sum_{\ell'} (w_{\ell\ell'} f_\ell - w_{\ell'\ell} f_{\ell'}).$$

(A1)

In the case of static disorder there is no room $^{29}$ for the Pauli blocking factors $(1 - f_\ell)$ and $(1 - f_{\ell'})$, which were introduced into the collision term of the Boltzmann equation phenomenologically by F. Bloch when studying phonon-limited mobility in metals in order to ensure the equilibrium Fermi distribution (rather than Bose or Boltzmann distributions) for $f_\ell^0$. In the case of dynamical disorder such as phonons, the Bloch-Boltzmann equation takes the form of Eq. (2a), where $w_{\ell\ell'}$ and $w_{\ell'\ell}$ are calculated in the quantum mechanical perturbation theory. The collision term is considered only in the linear response regime. To the lowest order in Born expansion, the principle of microscopic detailed balance holds, as can be directly verified for electron-phonon scattering. Thus $w_{\ell\ell'} = w_{\ell'\ell} e^{\beta(\epsilon_\ell - \epsilon_{\ell'})}$, and the Bloch-Boltzmann equation reads

$$eE \cdot v_\ell^0 \left( - \frac{\partial f_\ell^0}{\partial \epsilon_\ell} \right) = \sum_{\ell'} w_{\ell\ell'} \left[ f_\ell (1 - f_{\ell'}) - e^{\beta(\epsilon_\ell - \epsilon_{\ell'})} f_{\ell'} (1 - f_\ell) \right].$$

(A2)

The argument about introducing the coordinate-shift into this equation is similar to that in the case of static disorder, but is a little involved because $f_{\ell'}$ appears in both the scattering-in and scattering-out terms. In the scattering-out term $(\ell \to \ell')$ of Eq. (A2), the kinetic energy of an electron in state $\ell'$ after scattering out of state $\ell$ via absorbing (emitting) a phonon is $\epsilon_{\ell'} = \epsilon_\ell + \omega_q + eE \cdot \delta r_{\ell\ell'}$. In the scattering-in term $(\ell' \to \ell)$, the kinetic energy of an electron in state $\ell'$ before scattering into state $\ell$ via emitting (absorbing) a phonon is $\epsilon_\ell = \epsilon_{\ell'} - eE \cdot \delta r_{\ell'\ell}$. Thus in the linear response regime $(\epsilon_{\ell'} = \epsilon_\ell \pm h\omega_q)$, we have

$$\sum_{\ell'} w_{\ell\ell'} \left[ f_\ell (1 - f_{\ell'}) - e^{\beta(\epsilon_\ell - \epsilon_{\ell'})} f_{\ell'} (1 - f_\ell) \right]$$

$$= \sum_{\ell'} w_{\ell\ell'} \left\{ \left( f_0^0 (\epsilon_\ell) + \delta f_\ell \right) [1 - f_0^0 (\epsilon_{\ell'} + eE \cdot \delta r_{\ell\ell'}) - \delta f_{\ell'}] \right.$$

$$- e^{\beta(\epsilon_{\ell'} - \epsilon_\ell)} \left[ f_0^0 (\epsilon_{\ell'}) + eE \cdot \delta r_{\ell'\ell} \right] (1 - f_0^0 - \delta f_\ell) \left. \right\}$$

$$= \sum_{\ell'} w_{\ell\ell'} \left\{ f_0^0 (\epsilon_\ell) \left[ 1 - f_0^0 (\epsilon_{\ell'}) \right] - e^{\beta(\epsilon_{\ell'} - \epsilon_\ell)} f_0^0 (\epsilon_{\ell'}) \left( 1 - f_0^0 (\epsilon_\ell) \right) \right\}$$

(A3)

$$+ \sum_{\ell'} w_{\ell\ell'} \left\{ \left. - f_0^0 (\epsilon_{\ell'}) - e^{\beta(\epsilon_{\ell'} - \epsilon_\ell)} \left( 1 - f_0^0 (\epsilon_\ell) \right) \right| \frac{\partial f_0^0}{\partial \epsilon_{\ell'}} eE \cdot \delta r_{\ell'\ell} \right. \right\}$$

$$+ \sum_{\ell'} w_{\ell\ell'} \left\{ \delta f_\ell \left[ 1 - f_0^0 (\epsilon_{\ell'}) \right] - f_0^0 (\epsilon_{\ell'}) \delta f_{\ell'} + e^{\beta(\epsilon_{\ell'} - \epsilon_\ell)} \left[ f_0^0 (\epsilon_{\ell'}) \delta f_\ell - \delta f_{\ell'} (1 - f_0^0 (\epsilon_\ell)) \right] \right\} + O(E^2),$$

where $\delta f$ is the out-of-equilibrium distribution. On the right hand side of the last equality the first term is zero, and other two terms can be simplified, leading to the following modified Bloch-Boltzmann equation

$$eE \cdot v_\ell^0 \left( - \frac{\partial f_\ell^0}{\partial \epsilon_\ell} \right) = \sum_{\ell'} w_{\ell\ell'} \left[ \delta f_\ell \frac{1 - f_0^0 (\epsilon_{\ell'})}{1 - f_0^0 (\epsilon_\ell)} - \delta f_{\ell'} \frac{f_0^0 (\epsilon_{\ell'})}{f_0^0 (\epsilon_\ell)} \right] \frac{f_0^0 (\epsilon_\ell)}{f_0^0 (\epsilon_{\ell'})} eE \cdot \delta r_{\ell'\ell}.$$
By expressing $\delta f = g_\epsilon \left( -\frac{\partial f}{\partial \epsilon} \right)$, we arrive at Eq. [10] in the main text.

**Appendix B: Calculation details in the 2D massive Dirac model**

In the two-dimensional massive Dirac model, $\Omega_k = -\frac{\Delta^2}{2(\Delta^2 + (\epsilon - \omega_q)^2)^{3/2}}$ is the Berry-curvature in the positive band. Thus the side-jump velocity and the anomalous distribution are given by

$$v_{s,j}^i = -\frac{\Omega_k k_x}{\tau_{s,j}^i} \quad \text{and} \quad g_{k}^i = -eE_x \Omega_k k_y \frac{\tau_{s,j}^i}{\tau_{k}^i}. \quad (B1)$$

By using the identity

$$\frac{1 - f^0(\epsilon + \omega_q)}{1 - f^0(\epsilon)} N(\omega_q) + \frac{1 - f^0(\epsilon - \omega_q)}{1 - f^0(\epsilon)} \left[ N(\omega_q) + 1 \right] = \frac{f^0(\epsilon - \omega_q) - f^0(\epsilon + \omega_q)}{f^0(\epsilon) [1 - f^0(\epsilon)]} N(\omega_q) \left[ N(\omega_q) + 1 \right], \quad (B2)$$

the slight inelasticity of acoustic phonon scattering renders

$$\frac{1 - f_k^0}{1 - f_k^0} w_{k',k}^{q} = \frac{2\pi}{\hbar} |\langle u_{k'}|u_k \rangle|^2 |V_{k',k}^{q}|^2 \frac{2\hbar q}{k_BT} N_q \left( N_q + 1 \right) \delta(\epsilon_k - \epsilon_{k'}), \quad (B3)$$

where $q = 2k \sin \frac{1}{2} \phi_{kk'}$. Thus

$$\frac{\tau_{s,j}^{tr}}{\tau_{s,j}^i} = \frac{\int d\phi_{kk'} W_{\phi_{kk'}} (1 - \cos \phi_{kk'})}{\int d\phi_{kk'} |\langle u_{k'}|u_k \rangle|^2 W_{\phi_{kk'}} (1 - \cos \phi_{kk'})}, \quad (B4)$$

where

$$W_{\phi_{kk'}} = \lambda^2 k_BT \left( \frac{\hbar q}{k_BT} \right)^2 N_q \left( N_q + 1 \right), \quad (B5)$$

and $\lambda$ is the so-called electron-phonon coupling constant for the deformation-potential treatment of the electron-phonon coupling $[9, 45]: 2 |V_{k,k'}^{q}|^2 / \hbar q = \lambda^2$.

In the high-$T$ regime $W = \lambda^2 k_BT$ is uniformly distributed on the Fermi circle, and drops out of both the numerator and denominator of $\tau_{s,j}^{tr}/\tau_{s,j}^i$, thus $\sigma_{AH}^q$ takes the same $T$-independent value similar to that due to scalar zero-range impurities. While at low temperatures the temperature dependence of $N_q$ influences the integrals in $\tau_{s,j}^{tr}/\tau_{s,j}^i$, and $\sigma_{AH}^q$ becomes $T$-dependent. In the low-$T$ limit $W/k_BT$ is highly peaked around $\phi_{kk'} = 0$ hence $|\langle u_{k'}|u_k \rangle|^2 \rightarrow 1$, $\tau_{s,j}^{tr}/\tau_{s,j}^i \rightarrow 1$ and $\sigma_{AH}^q$ coincides with that due to long-range scalar-impurities $[46]$. 

**Appendix C: Generalized Bloch-Boltzmann formalism from the density matrix approach**

To prove the validity of Eqs. [10] – [12] in the main text, in the following two sections, we provide the microscopic formalism for the Boltzmann formalism in weakly coupled electron-phonon systems. Firstly, the density-matrix equation-of-motion approach $[39, 40]$ is applied to the many-particle density matrix for the whole electron-phonon system $[41]$. The quantum Liouville equation is analyzed in the occupation number representation perturbatively with respect to the coupling parameter. Aside from the usual assumption that the phonon system remains approximately in thermal equilibrium $[11, 42, 44]$, a basic statistical assumption is needed, which is analogous to the assumption of molecular chaos made in deriving the classical Boltzmann equation from the classical Liouville equation $[47]$. We also show that the side jump contribution is connected to the scattering-induced interband-coherence responses in the microscopic transport theory, similar to the case of static disorder $[19, 24]$. This clearly goes beyond the relaxation time treatment where the effect of phonons is embodied only in an inelastic lifetime of electrons $[13]$.

For discussing problems in a quantum many-particle system, the second quantized formalism is a common starting point. We introduce the notation $\hat{A}$ to denote the representation of an operator $A$ in the second-quantized formalism. For a single-particle operator, i.e., $\hat{A} = \sum_i \hat{A}_i$ where $\hat{A}_i$ depends only on the dynamical variables of the $i$-th carrier, we write $\hat{A} = \sum_{\ell \ell'} A_{\ell \ell'} a_{\ell'}^\dagger a_{\ell}$ where $A_{\ell \ell'}$ is the corresponding matrix elements in the $\ell$ representation, $a_{\ell}^\dagger$ and $a_{\ell}$ are the
creation and annihilation operators for the single-electron state \( |\ell\rangle \). The original version of Kohn-Luttinger density-matrix approach \[39\] rests on the existence of a single-electron Hamiltonian which contains all the information in the case of independent electrons interacting with static disorder. In the case of dynamical disorder such as phonons and magnons, as first pointed out by Argyres \[41\], one can apply the Kohn-Luttinger treatment to the many-body density matrix approach \[39\] which retains theRemember to replace the placeholder with the appropriate text.

\[ H_T = \hat{H}_e + \hat{H}' + \hat{H}_F + \hat{H}_s, \]  

(\text{C1})

where \( \hat{H}_e = \sum_{m,n} a_{m}^\dagger a_{n} \) is the electron Hamiltonian in the absence of external electric fields and scattering, and \( \hat{H}_F = \sum_{m,n} a_{m}^\dagger a_{n} \) is the external-electric-field perturbation with \( \hat{H}_F = \hat{H}_1 e^{\ast t} (\hat{H}_1 = -e\mathbf{E} \cdot \mathbf{r}) \) turned on adiabatically from the remote past. The electric field is turned on much more slowly than the scattering time \( (s \rightarrow 0^+) \) \[39, 49\]. \( \hat{H}_s \) is the Hamiltonian of the scattering system, and \( \hat{H}' = \lambda \hat{N} \) is the interaction of electrons with the scattering system, where \( \lambda \) is a dimensionless parameter used for analyzing the order in the perturbative analysis and is set to 1 eventually. \( (\hat{H}')_{m,n} \) is still an operator in the Hilbert space of the scattering system. In the occupation number representation \( \{ |nN\rangle \} \), \( \hat{H}_e |nN\rangle = \sum_{\varepsilon} \varepsilon \hat{n}_\varepsilon |nN\rangle = E_n |nN\rangle \) and \( \hat{H}_s |nN\rangle = E_N |nN\rangle \). Hereafter we set \( E_{nN} = E_n + E_N \), and \( n \) and \( N \) are the many-particle state indices for the electron system and scattering system, respectively. \( \hat{n}_\varepsilon = a_{\varepsilon}^\dagger a_{\varepsilon} \) and its eigenvalue \( n_\varepsilon \) denotes the electron number on the Bloch state marked by the index \( \ell \) with single-electron eigenenergy \( \varepsilon_\ell \). In the linear response regime the total many-particle density matrix reads

\[ \hat{\rho}_T = \hat{\rho} + \hat{F} e^{\ast t}, \]  

(C2)

where \( \hat{\rho} \) is the equilibrium many-particle density matrix for the whole system, and \( \hat{F} \) is linear in the electric field. The quantum Liouville equation

\[ i\hbar \frac{\partial}{\partial t} \hat{\rho}_T = [\hat{H}_T, \hat{\rho}_T] \]  

(C3)

becomes \( \mathbf{i} \hbar \hat{\rho}_T = \left[ \hat{H}_0 + \hat{H}_s + \hat{H}', \hat{F} \right] + \left[ \hat{H}_1, \hat{\rho} \right] \). In the occupation number representation \( \{ |nN\rangle \} \) one has

\[ (E_{nN} - E_{n'N'} - i\hbar s) \hat{F}_{nN,n'N'} = \sum_{n',n''} (\hat{F}_{nN,n''N'} \hat{H}_{n''N'',n'N'} - \hat{H}_{nN,n''N'} \hat{F}_{n''N'',n'N'}) + \hat{C}_{nN,n'N'}, \]  

(C4)

where \( \hat{C}_{nN,n'N'} = \left[ \hat{\rho}, \hat{H}_1 \right]_{nN,n'N'} \). Hereafter we sometimes use the notation \( L = nN \), \( L' = n'N' \) to simplify expressions.

The linear response of an observable \( A \) is \( \delta A = \text{Tr} (\hat{F} \hat{A}) = \sum_{LL'} \hat{F}_{LL'} \hat{A}_{L'L} = \sum_{LL'} \hat{F}_{LL'} \hat{A}_{L'L} \) where \( \text{Tr} \) denotes the trace operation in the occupation-number space, and the notation \( \sum' \) means that all the index equalities in the summation are avoided. Here we first outline the main results of the following detailed derivation. The linear response of the velocity of electrons is

\[ \delta \mathbf{v} = \text{Tr} \left( \hat{F} \hat{\mathbf{v}} \right) = \sum_L \hat{F}_L \hat{\mathbf{v}}_{LL} + \sum_{LL'} \hat{F}_{LL'} \hat{\mathbf{v}}_{L'L}. \]  

(C5)

To obtain \( \hat{F}_L \) and \( \hat{F}_{LL'} \) in the weakly coupled system we make a perturbative analysis of Eq. \( (\text{C4}) \) with respect to the coupling parameter. The off-diagonal elements \( \hat{F}_{LL'} \) can be expressed in terms of the diagonal ones \( \hat{F}_L \), resulting in an equation for \( \hat{F}_L \). Because by definition \( \hat{f}_{\ell} = \text{Tr} \left( \hat{n}_\ell \hat{\rho} \right) = \sum_L n_\ell \hat{\rho}_L \) and

\[ \delta f_{\ell} = \text{Tr} \left( \hat{n}_\ell \hat{F} \right) = \sum_L n_\ell \hat{F}_L, \]  

(C6)

we derive the modified Bloch-Boltzmann equation \( (10) \) of the main text based on the equation for \( \hat{F}_L \). According to Eq. \( (\text{C6}) \) one has

\[ \sum_L \hat{F}_L \hat{\mathbf{v}}_{LL} = \sum_L \hat{F}_L \sum_\ell \mathbf{v}_0 \hat{n}_\ell = \sum_\ell \delta f_\ell \mathbf{v}_0. \]  

(C7)
Whereas $\sum_{LL'} \tilde{F}_{LL'} \tilde{\nu}_{LL'}$ is proven to yield the transport contributions from the Berry-curvature anomalous velocity and the side-jump velocity:

$$
\sum_{LL'} \tilde{F}_{LL'} \tilde{\nu}_{LL'} = \sum_{\ell} f_{\ell}^0 \nu_{\ell}^{bc} + \sum_{\ell} \delta f_{\ell}^n \left[ \sum_{\ell'} \frac{1 - f_{\ell'}^0}{1 - f_{\ell}^0} w_{\ell'\ell} \delta r_{\ell'\ell} \right],
$$

(8)

where $\delta r_{\ell'\ell}$ is given by Eq. (3) of the main text. We also show that the side-jump velocity $\nu_{\ell}^3 = \sum_{\ell'} \frac{1 - f_{\ell'}^0}{1 - f_{\ell}^0} w_{\ell'\ell} \delta r_{\ell'\ell}$ arises from scattering-induced interband-coherence, so does the anomalous distribution function $g_{\ell}^1$. (Eqs. (11) and (12)).

1. Perturbative analysis of the quantum Liouville equation

We split the quantum Liouville equation into diagonal and off-diagonal parts in the $|nN\rangle$-representation:

$$
(E_{nN} + \tilde{H}_{nN'} - E_{n'N'} - i\hbar s) \tilde{F}_{nN,n'N'} = \sum_{n''N''}^{'} \left( \tilde{F}_{nN,n''N''} \tilde{H}_{n''N''} + \tilde{F}_{nN,n''N''} \tilde{F}_{n''N'',n'N'} \right)
+ \left( \tilde{F}_{nN} - \tilde{F}_{n'N'} \right) \tilde{H}_{nN,n'N'} + \tilde{C}_{nN,n'N'},
$$

(9)

for $nN \neq n'N'$, and

$$
- i\hbar s \tilde{F}_{nN} = \sum_{n'N'}^{'} \left( \tilde{F}_{nN,n'N'} \tilde{H}_{n'N',nN} + \tilde{F}_{nN,n'N'} \tilde{F}_{n'N',nN} \right) + \tilde{C}_{nN}.
$$

(10)

According to the spirit of the Boltzmann theory, the first-order energy shift $\tilde{H}_{nN}$ is incorporated into the renormalization of the band energy and henceforth neglected $^{39, 40}$. To solve these two equations in the weak coupling regime we make the standard order-by-order analysis with respect to the coupling parameter of the interaction with disorder:

$$
\tilde{F}_{nN} = \tilde{F}_{nN}^{(-2)} + \tilde{F}_{nN}^{(-1)} + \tilde{F}_{nN}^{(0)} + \ldots,
$$

$$
\tilde{F}_{nN,n'N'} = \tilde{F}_{nN,n'N'}^{(-1)} + \tilde{F}_{nN,n'N'}^{(0)} + \tilde{F}_{nN,n'N'}^{(1)} + \tilde{F}_{nN,n'N'}^{(2)} + \ldots,
$$

(11)

Hereafter the superscript $(i)$ denotes the order in $\lambda$.

For Eq. (9) one can obtain: in $O (\lambda^{-1})$

$$
(E_{nN} - E_{n'N'} - i\hbar s) \tilde{F}_{nN,n'N'}^{(-1)} = \left[ \tilde{F}_{nN}^{(-2)} - \tilde{F}_{n'N'}^{(-2)} \right] \tilde{H}_{n'N'},
$$

(12)

in $O (\lambda)$

$$
[ E_{nN} - E_{n'N'} - i\hbar s ] \tilde{F}_{nN,n'N'}^{(0)} = \sum_{n''N''}^{'} \left[ \tilde{F}_{nN,n''N''}^{(-1)} \tilde{H}_{n''N'',n'N'} - \tilde{H}_{nN,n''N''} \tilde{F}_{n''N'',n'N'}^{(-1)} \right]
+ \left[ \tilde{F}_{nN}^{(-1)} - \tilde{F}_{n'N'}^{(-1)} \right] \tilde{H}_{nN,n'N'} + \tilde{C}_{nN,n'N'},
$$

(13)

in $O (\lambda)$

$$
[ E_{nN} - E_{n'N'} - i\hbar s ] \tilde{F}_{nN,n'N'}^{(1)} = \sum_{n''N''}^{'} \left[ \tilde{F}_{nN,n''N''}^{(0)} \tilde{H}_{n''N'',n'N'} - \tilde{H}_{nN,n''N''} \tilde{F}_{n''N'',n'N'}^{(0)} \right]
+ \left[ \tilde{F}_{nN}^{(0)} - \tilde{F}_{n'N'}^{(0)} \right] \tilde{H}_{nN,n'N'} + \tilde{C}_{nN,n'N'},
$$

(14)

For Eq. (9) one can obtain: in $O (\lambda)$

$$
0 = \sum_{n'N'}^{'} \left[ \tilde{F}_{nN,n'N'}^{(-1)} \tilde{H}_{n'N',nN} - \tilde{H}_{nN,n'N'} \tilde{F}_{n'N',nN}^{(-1)} \right] + \tilde{C}_{nN},
$$

(15)
in $O(\lambda)$

$$0 = \sum_{n', n''} \left[ \tilde{F}_{nN,n',n''} \tilde{H}_{n',n''} - \tilde{H}_{nN,n',n''} \tilde{F}_{nN,n',n''} \right] + \tilde{C}^{(1)}_{nN}. \quad (C16)$$

in $O(\lambda^2)$

$$0 = \sum_{n', n''} \left[ \tilde{F}_{nN,n',n''} \tilde{H}_{n',n''} - \tilde{H}_{nN,n',n''} \tilde{F}_{nN,n',n''} \right] + \tilde{C}^{(2)}_{nN}. \quad (C17)$$

For simplicity we assume the bosonic quasi-particles of the dynamical scattering systems, e.g., phonons and/or magnons, can be approximately thought to be in thermal equilibrium. Although this standard assumption after F. Bloch [11] can only be clearly justified at high temperatures, it was shown to work well in many cases beyond that regime [11 9 30]. Here we adopt it to simplify the derivation (which is still quite tedious even after making this assumption).

The off-diagonal (with respect to $L$) elements $\tilde{F}_{LL'}$ can be expressed in terms of the diagonal ones $\tilde{F}_{L}$, and $\tilde{F}_{L}$ are related to the diagonal (in the single-electron Bloch representation) elements of the single-electron density matrix (Eq. [C0]). Thus the Bloch-Boltzmann theory formulated in the single-electron Bloch representation can be derived from the microscopic transport theory presented in the occupation number representation.

2. Perturbative calculation of $C_{LL'}$

Applying the Karplus-Schwinger expansion [31]

$$e^{\hat{A} + \hat{B}} = e^{\hat{A}} + \int_0^1 d\lambda e^{(1-\lambda)\hat{A}} \hat{A} e^{\lambda \hat{A}} + \int_0^1 d\lambda e^{(1-\lambda)\hat{A}} \hat{B} e^{\lambda \hat{A}} \int_0^\lambda d\lambda' e^{-\lambda' \hat{A}} \hat{B} e^{\lambda' \hat{A}} + ... \quad (C18)$$

up to the second order of $B$ one can calculate the equilibrium density matrix $\hat{\rho} = Z^{-1} e^{\hat{A} + \hat{B}} (\hat{A} = -\beta \left( \hat{H}_e - \mu \hat{N}_e + \hat{H}_s \right), \hat{B} = -\beta \hat{H}')$ in weakly coupled systems. The partition function is given by $Z^{-1} \approx Z_0^{-1} (1 + \gamma)$, where $Z_0 = \sum_L e^{\hat{A}_L}$ and $\gamma \sim o(B^2)$. We have ($\hat{\rho}^{(0)} = Z_0^{-1} e^{\hat{A}}$)

$$\tilde{C}^{(0)} = \left[ \tilde{\rho}^{(0)}, \hat{H}_1 \right] = Z_0^{-1} (-eE) \cdot \exp (-\beta \hat{H}_s) \left[ \exp \left( -\beta \sum_j \hat{H}_e \left( j \right) \right), \sum_i \tilde{\hat{r}}_i \right]$$

$$= (-eE) \cdot \tilde{\rho}^{(0)} \sum_{\ell \ell'} \exp (\beta \epsilon \ell) \left[ \exp (-\beta \hat{H}_e), \tilde{\hat{r}} \right] a^\dagger_{\ell \ell'} a_{\ell \ell'}$$

$$= i \tilde{\rho}^{(0)} eE \cdot \left\{ \sum_{\ell \ell'} J_{\ell \ell'} \left[ \exp \left( -\beta (\epsilon_{\ell'} - \epsilon_\ell) \right) - 1 \right] a_{\ell \ell'} a^\dagger_{\ell \ell'} + (-\beta) \sum_{\ell} \frac{\partial \epsilon \ell}{\partial \tilde{\ell}} \tilde{\rho}^{(0)} \right\},$$

then

$$\tilde{C}^{(0)}_{\ell \ell', n, n'} = i eE \cdot \sum_{\ell \ell'} J_{\ell \ell'} \left( e^{-\beta (\epsilon_{\ell'} - \epsilon_\ell) - 1} \right) \tilde{\rho}^{(0)}_{nN} \left( a_{\ell}^\dagger a_{\ell'} \right)_{n, n'} (1 - \delta_{n, n'}) + (-\beta) \sum_{\ell} \frac{\partial \epsilon \ell}{\partial \tilde{\ell}} \tilde{\rho}^{(0)} \delta_{n, n'}. \quad (C19)$$

Next we look at

$$\tilde{C}^{(1)} = \left[ \tilde{\rho}^{(1)}, \hat{H}_1 \right] = \frac{1}{Z_0} \left[ \int_0^1 d\lambda e^{(1-\lambda)\hat{A}} \hat{B} e^{\lambda \hat{A}}, \hat{H}_1 \right]$$

$$= \frac{1}{Z_0} \int_0^1 d\lambda \sum_{\ell \ell'} e^{(1-\lambda)(\hat{R}_e + \tilde{\ell})} e^{\lambda \hat{R}_e + \tilde{\ell}} a^\dagger_{\ell \ell'} a_{\ell \ell'} e^{(1-\lambda)(\hat{R}_e + \hat{H}_e)} e^{-\lambda \hat{A}_I} \left[ e^{\lambda \hat{R}_e}, \hat{H}_1 \right]_{\ell \ell'}$$

$$+ e^{(1-\lambda)(\hat{R}_e + \hat{H}_e)} e^{-(1-\lambda)\hat{A}_I} e^{(1-\lambda)\hat{H}_e} e^{\lambda \hat{R}_e} \left[ e^{(1-\lambda)\hat{H}_e}, \hat{H}_1 \right]_{\ell \ell'} a^\dagger_{\ell \ell'} a_{\ell \ell'} e^{\lambda \hat{R}_e}.$$
There are so many terms that one should have some guiding principle to simplify the analysis. According to the insight we obtained in the discussion of static-disorder case [40], some trivial renormalization effects can be neglected and only the diagonal (in the Bloch representation for electrons) elements of electric-field perturbation survive in the final contribution to $\tilde{C}_{\ell\ell}^{(\prime)}$, which appears in the following Eq. (C34) as an anomalous driving term [39,40]. Thus, we obtain

$$
\tilde{C}_{nN,n'N'}^{(1)} = \sum_{\ell \ell'} i e E \left[ (J_{\ell} - J_{\ell'}) \tilde{H}_{\ell e',\ell' e}^{(0)} + i H_{\ell e',\ell' e}^{(0)} \tilde{D} \arg H_{\ell e',\ell' e}^{(0)} \right] \left( a^\dagger_{n' e'} a_{n e} \right) \frac{\rho^{(0)}_{n' N'} - \rho^{(0)}_{n N}}{E_{n' N'} - E_{n N}}.
$$

where $\tilde{D} = \delta_{k} + \delta_{k'}$, $J_{\ell} = (u_{\ell} | \delta_{k} | u_{\ell'})$ and $J_{\ell e'} = \delta_{k \ell e} (u_{\ell} | \delta_{k} | u_{\ell'})$. Meanwhile the anomalous driving term that will appear in Eq. (C34)

$$
\tilde{C}_{nN} = \sum_{n' N'} \left[ \tilde{C}_{nN,n'N'}^{(1)} \tilde{H}_{n' N',n N}^{(0)} - \text{c.c.} \right]
$$

only contains nontrivial correction to the driving term of the transport equation with $\tilde{C}_{LL}^{(1)}$ given by Eq. (C20). One can verify that $\tilde{C}_{nN,n'N'}^{(1)} = -\tilde{C}_{n'N',nN}^{(1)}$. Henceforth $\tilde{d}_{nN,n'N'}^{(0)} = E_{n N} - E_{n' N'} \mp i \hbar \omega$. In the above derivation we used $[\hat{\rho}, \hat{r}]_{\ell e'} = -i \sum_{e''} (J_{\ell e''} \rho_{e'' e'} - \rho_{e' e''} J_{e'' e'}) - i \tilde{D} \rho_{e' e''}$ for $\ell \neq \ell'$ and $[\hat{\rho}, \hat{r}]_{\ell \ell} = -i \sum_{e''} (J_{\ell e''} \rho_{e'' e} - \rho_{e' e''} J_{e'' e'}) - i \frac{\partial}{\partial \epsilon_{\ell}} \rho_{e' e}$. 

3. Conventional Bloch-Boltzmann equation

In the zeroth order of electron-disorder interaction one has

$$
0 = \tilde{C}_{L}^{(0)} + i h \sum_{L'} \tilde{\omega}_{LL'}^{(2)} \left[ \tilde{F}_{L}^{(0)} - \tilde{F}_{L'}^{(0)} \right]
$$

with $\tilde{\omega}_{LL'}^{(2)} = 2 \pi \frac{E}{\hbar} \left| \tilde{H}_{LL'}^{(0)} \right|^2 \delta (E_{n N} - E_{n' N'})$. Then

$$
0 = \sum_{n N} n_{e} \tilde{C}_{nN}^{(0)} + 2 \pi i \sum_{n' N' \ell \ell'} \left| \tilde{H}_{\ell e',\ell' e}^{(0)} \right|^2 \delta (E_{n N} - E_{n' N'}) \left( n_{\ell} - n'_{\ell} \right) F_{n N}^{(2)},
$$

where

$$
\sum_{n N} n_{e} \tilde{C}_{nN}^{(0)} = i e E \cdot (-\beta) \sum_{e'} \sum_{N} \frac{\partial f_{e'}}{\partial k} \sum_{n} n_{e} \rho_{n e}^{(0)} = (-\beta) i e E \cdot \sum_{e'} \frac{\partial f_{e'}}{\partial k} \sum_{n} n_{e} \rho_{n e}^{(0)}
$$

$$
= i e E \cdot \frac{\partial f_{e'}}{\partial k} \left( 1 - f_{e'}^{0} \right) = i e E \cdot \frac{\partial f_{e}}{\partial k} = i e E \cdot \frac{\partial f}{\partial k}.
$$

and

$$
2 \pi i \sum_{n' N' \ell \ell'} \left| \tilde{H}_{\ell e',\ell' e}^{(0)} \right|^2 \delta (E_{n N} - E_{n' N'}) \left( n_{\ell} - n'_{\ell} \right) F_{n N}^{(2)}
$$

$$
= 2 \pi i \sum_{n' N' \ell \ell'} \sum_{e''} \left| \tilde{H}_{\ell e',\ell' e}^{(0)} \right|^2 n_{\ell} \left( 1 - n_{e'} \right) \delta_{e'' = e'} \delta_{n_{\ell} - 1 = n'_{\ell}} \delta_{n_{e'} + 1 = n'_{e'}} \delta (E_{N} - E_{N'} + \epsilon_{\ell} - \epsilon_{e'}) \left( n_{k} - n'_{k} \right) F_{n N}^{(2)}
$$

$$
= i \hbar \sum_{n' N' \ell' e'} \left[ \omega_{kn e'}^{2} n_{k} \left( 1 - n'_{\ell'} \right) - \omega_{kn e'}^{2} \left( 1 - n_{\ell} \right) \right] F_{n N}^{(2)}.
$$

In the derivation one uses

$$
\left( a_{n e}^\dagger a_{n' e'} \right)_{n', n} = \delta_{k \ell} \delta_{e' e} n_{\ell} \left( 1 - n_{e'} \right) \delta_{n_{\ell} - 1 = n'_{\ell}} \delta_{n_{e'} + 1 = n'_{e'}}.
$$

(C25)
Thus we obtain \[ (26) \]
\[
e E \cdot \frac{\partial f_0^0}{\hbar \partial k} + \sum_{nN,N'} \sum_{\ell} \left[ \omega_{2N,N'}^2 n_\ell (1-n_{\ell'}) - \omega_{2N,N'}^2 n_{\ell'} (1-n_\ell) \right] \tilde{F}_{nN}^{(-2)} = 0,
\]
where \( \omega_{2N,N'}^2 = \frac{2\pi}{\hbar^2} \left| H'_{N,N'} \right|^2 \delta \left( E_N - E_{N'} + \epsilon_\ell - \epsilon_{\ell'} \right) \). Since the bosonic quasi-particles of the dynamical scattering systems (e.g., phonons or magnons) are assumed to remain in equilibrium, we introduce the following assumption for factorizing the entire many-particle density matrix \[ (27) \]
\[
\tilde{F}_{nN}^{(-2)} = f_0^0 \tilde{F}_{nN}^{(-2)},
\]
then
\[
\sum_{nN,N'} \sum_{\ell} \left[ \omega_{2N,N'}^2 n_\ell (1-n_{\ell'}) - \omega_{2N,N'}^2 n_{\ell'} (1-n_\ell) \right] \tilde{F}_{nN}^{(-2)} = \sum_{\ell} \left[ \omega_{\ell}^2 n_\ell (1-n_{\ell'}) - \omega_{\ell'}^2 n_{\ell'} (1-n_\ell) \right] \tilde{F}_{nN}^{(-2)},
\]
where
\[
\omega_{\ell}^2 = \sum_{N,N'} f_0^0 \omega_{2N,N'} \sum_{\ell} \left| H'_{N,N'} \right|^2 \delta \left( E_N - E_{N'} + \epsilon_\ell - \epsilon_{\ell'} \right),
\]
\[
\omega_{\ell'}^2 = \sum_{N,N'} f_0^0 \omega_{2N,N'} \sum_{\ell} \left| H'_{N,N'} \right|^2 \delta \left( E_{N'} - E_N + \epsilon_\ell - \epsilon_{\ell'} \right).
\]

Now one has to introduce another basic statistical assumption, i.e.,
\[
\sum_n n_\ell n_{\ell'} \tilde{F}_{nN}^{(-2)} = \left[ f_\ell f_{\ell'} \right]^{(-2)} = f_\ell^0 f_{\ell'}^{(-2)} + f_\ell^0 f_{\ell'} - f_\ell^0 f_{\ell'}^2,
\]
which is analogous to the assumption of molecular chaos introduced in deriving the classical Boltzmann equation from the classical Liouville equation (BBGKY hierarchy) \[ (29) \]. Therefore, under the assumptions \[ (27) \] and \[ (29) \], one arrives at the Boltzmann equation for \( f^{(-2)}_\ell \):
\[
e E \cdot \frac{\partial f_\ell^0}{\hbar \partial k} + \sum_{\ell'} \left[ \omega_{\ell\ell'}^2 \left( f^{(-2)}_\ell - \left[ f_\ell f_{\ell'} \right]^{(-2)} \right) - \omega_{\ell'\ell}^2 \left( f^{(-2)}_{\ell'} - \left[ f_\ell f_{\ell'} \right]^{(-2)} \right) \right] = 0,
\]
which is just the linearized Bloch-Boltzmann equation. Utilizing the microscopic detailed balance that can be verified directly in the lowest order perturbation theory, one has
\[
\omega_{\ell\ell'}^2 f_\ell^0 \left( 1-f_{\ell'}^0 \right) = \omega_{\ell'\ell}^2 f_{\ell'}^0 \left( 1-f_\ell^0 \right)
\]
and \( \delta f_\ell \equiv f_\ell - f_{\ell'}^0 \)
\[
\delta f_\ell \left( 1-f_{\ell'}^0 \right) + f_{\ell'}^0 \left( 1-f_\ell \right) - f_\ell^0 \left( 1-f_{\ell'}^0 \right) + f_{\ell'}^0 \left( 1-f_\ell \right) = \delta f_\ell \frac{1-f_{\ell'}^0}{1-f_\ell^0} = \delta f_{\ell'} \frac{1-f_\ell^0}{1-f_{\ell'}^0}
\]
thus
\[
e E \cdot \frac{\partial f_\ell^0}{\hbar \partial k} + \sum_{\ell'} \omega_{\ell\ell'}^2 \left[ f^{(-2)}_\ell \left( 1-f_{\ell'}^0 \right) - f^{(-2)}_{\ell'} \left( 1-f_\ell^0 \right) \right] = 0,
\]
which is just the practical form of the Bloch-Boltzmann equation, i.e., Eq. \[ (2b) \] in the main text (note that \( \omega_{\ell\ell'}^2 \equiv \omega_{\ell'}^2 \) and \( f^{(-2)}_\ell = \delta f_\ell^0 \)).

In the case of static disorder, the conventional skew scattering appears in the Boltzmann equation in the first order of disorder potential \[ (30) \]. The harmonic approximation is assumed for the scattering system, then one has
\[
\omega_{LL'}^0 = \omega_{LL'}^0 = 0, \quad C_L^{(1)} = 0 \quad \text{and} \quad C_{LL'}^{(0)} = C_{LL'}^{(1)} = 0.
\]
Thus \( \tilde{F}_{L}^{(-1)} = 0 \) and \( f_\ell^{(-1)} = 0 \). This leads to vanishing conventional skew scattering due to phonons, as pointed out in Refs. \[ (15) \] \[ (29) \] \[ (38) \] and experimentally confirmed in Refs. \[ (11) \] \[ (15) \].
4. Anomalous distribution function

In the second order of disorder potential the transport equation for $\tilde{F}_L^{(0)}$ can be decomposed into

$$0 = \tilde{C}'' + i\hbar \sum_{L'} \tilde{\omega}^{(2)}_{LL'} \left[ \tilde{F}^{(0),a}_L - \tilde{F}^{(0),a}_{L'} \right]$$

(C34)

and $0 = \sum_{L'} \tilde{\omega}^{(2)}_{LL'} \left[ \tilde{F}^{(0),n}_L - \tilde{F}^{(0),n}_{L'} \right] + i\hbar \sum_{L'} \left[ \tilde{\omega}^{(4)}_{LL'} \tilde{F}^{(2)}_{LL'} - \tilde{\omega}^{(4)}_{LL'} \tilde{F}^{(-2)}_{LL'} \right]$, where $\tilde{F}^{(0)}_L = \tilde{F}^{(0),n}_L + \tilde{F}^{(0),a}_L$ and $\tilde{C}''$ is given by Eq. (C21). Here we only analyze the equation for $\tilde{F}^{(0),a}_L$, yielding the anomalous distribution that is related to the side jump effect. $\tilde{F}^{(0),n}_L$ is related to the so-called intrinsic skew scattering, which is not likely to have an intuitive generic description in the case of dynamical disorder (38).

Utilizing

$$\sum_{nN} n_k \sum_{n'N'} \left[ \tilde{C}^{(1)}_{nN,n'N'} H_{n'N',nN}/d_{nN,n'N'} + c.c. \right] = \sum_{nN} \left( n_k - n'_k \right) \tilde{C}^{(1)}_{nN,n'N'} H_{n'N',nN}/d_{nN,n'N'}$$

and Eq. (C25) and similar techniques to those in deriving the conventional Bloch-Boltzmann equation, we get

$$\sum_{nN} \sum_{n'N'} \frac{1}{\eta} \left[ \omega^{(2)}_{\ell\ell'} f^{(0)} (1 - f^{(0)}_0) \right] = \sum_{nN} \left[ \frac{1}{\eta} \omega^{(2)}_{\ell\ell'} \right] \partial f^{(0)}_0 \partial \epsilon \ell \ell'$$

(C35)

By Eq. (C31), we obtain

$$\sum_{nN} \sum_{n'N'} \frac{1}{\eta} \left[ \omega^{(2)}_{\ell\ell'} f^{(0)} (1 - f^{(0)}_0) \right] = -i\hbar \mathbf{E} \cdot \sum_{\ell' \ell''} \left[ \omega^{(2)}_{\ell\ell'} \delta \mathbf{r}_{\ell' \ell''} \left( 1 - f^{(0)}_0 \right) \right]$$

(C36)

Then we treat the collision term by employing the basic assumption

$$\tilde{F}^{(0),a}_n = F^{(0)}_n \tilde{F}^{(0),a}_n$$

(C37)

and the “assumption of molecular chaos”

$$\sum_{nN} n_k n'_k \tilde{F}^{(0),a}_n = \left[ f_{\ell} f^{(0),a}_{\ell'} \right]_n \equiv f^{(0),a}_\ell f^{(0),a}_{\ell'} + f^{(0),a}_\ell f^{(0),a}_{\ell'}$$

(C38)

yielding the Boltzmann equation for $f^{(0),a}_\ell$:

$$0 = -\epsilon \mathbf{E} \cdot \sum_{\ell'} \left[ \frac{1 - f^{(0),a}_{\ell'}}{1 - f^{(0),a}_{\ell'}} \omega^{(2)}_{\ell\ell'} \delta \mathbf{r}_{\ell' \ell} \right] \partial f^{(0),a}_\ell \partial \epsilon \ell + \sum_{\ell'} \left[ \omega^{(2)}_{\ell\ell'} \left[ f_{\ell} \left( 1 - f^{(0),a}_{\ell'} \right) \right] - \omega^{(2)}_{\ell\ell'} \left[ f_{\ell'} \left( 1 - f^{(0),a}_{\ell} \right) \right] \right]$$

(C39)

Utilizing Eqs. (C31) and (C32), we get

$$0 = -\epsilon \mathbf{E} \cdot \sum_{\ell'} \left[ \frac{1 - f^{(0),a}_{\ell'}}{1 - f^{(0),a}_{\ell'}} \omega^{(2)}_{\ell\ell'} \delta \mathbf{r}_{\ell' \ell} \right] \partial f^{(0),a}_\ell \partial \epsilon \ell + \sum_{\ell'} \omega^{(2)}_{\ell\ell'} \left[ f^{(0),a}_{\ell} \frac{1 - f^{(0),a}_{\ell'}}{1 - f^{(0),a}_{\ell'}} f^{(0),a}_{\ell'} \right]$$

(C40)

This is exactly the same Boltzmann equation for the anomalous distribution function $f^{(0),a}_\ell$ as we obtained via phenomenological arguments in the main text.
5. Berry curvature anomalous velocity and side-jump velocity

For the observables of interest, \( \hat{A} \) is diagonal with respect to \( N \), hence \( \tilde{F}_{LL'}^{(-1)} \) does not contribute to the off-diagonal response, and the off-diagonal response \( \sum_{LL'}^{t} \tilde{F}_{LL'} A_{LL'} \) is equal to

\[
\sum_{LL'}^{t} \tilde{F}_{LL'}^{(0)} \hat{A}_{LL'} = \delta^{in} A + \delta^{3} A, \tag{C41}
\]

where

\[
\delta^{in} A \equiv \sum_{LL'}^{t} C_{LL'}^{(0)} \frac{\hat{A}_{LL'}}{E_{L} - E_{L'} - i\hbar s} \tag{C42}
\]

is the intrinsic part, whereas

\[
\delta^{3} A \equiv \sum_{LL'}^{t} \tilde{F}_{LL'}^{(-2)} \left[ \left( \frac{H_{LL'}^{LL'} H_{LL'}^{LL'} \hat{A}_{LL'}}{d_{LL'} \bar{d}_{LL'}} + \text{c.c.} \right) + \frac{H_{LL'}^{LL'} H_{LL'}^{LL'} \hat{A}_{LL'}}{d_{LL'} \bar{d}_{LL'}} \right] \tag{C43}
\]

is the disorder-dependent part.

a. Intrinsic contribution: electric-field induced interband-coherence

Due to Eqs. \[ \text{(C19)} \] and \[ \text{(C25)} \], we have \( \langle \hat{\rho}_{nN}^{(0)} = P_{N}^{(0)} \hat{\rho}_{nN}^{(0)} \rangle \)

\[
\delta^{in} A = i e \mathbf{E} \cdot \sum_{n,n'}^{t} \mathbf{J}_{\ell\ell'} \left( e^{-\beta (\epsilon_{\ell'} - \epsilon_{\ell})} - 1 \right) \hat{\rho}_{nN}^{(0)}(a_{\ell}^\dagger a_{\ell'})_{n,n'} \frac{\hat{A}_{n'nN,nN}}{E_{n} - E_{n'} - i\hbar s} \]

\[
= \sum_{n,n'}^{t} i e \mathbf{E} \cdot \sum_{\ell\ell'} \mathbf{J}_{\ell\ell'} A_{\ell\ell'} \left( -\hat{\rho}_{nN}^{(0)} \right) \frac{\hat{A}_{n'nN,nN}}{\epsilon_{\ell} - \epsilon_{\ell'} - i\hbar s} \left[ n_{\ell} \left( 1 - n_{\ell'} \right) \delta_{n_{\ell}-1=n_{\ell}} \delta_{\epsilon_{\ell}+1=n_{\ell}} - n_{\ell} \left( 1 - n_{\ell'} \right) \delta_{n_{\ell}-1=n_{\ell}} \delta_{\epsilon_{\ell}+1=n_{\ell}} \right],
\]

where we used \( \hat{\rho}_{nN}^{(0)} \left[ e^{-\beta (E_{n'} - E_{n})} - 1 \right] = \delta^{(0)}_{nN} - \hat{\rho}_{nN}^{(0)}. \) Notice that for fermions

\[
n_{\ell} \left( 1 - n_{\ell'} \right) \delta_{n_{\ell}-1=n_{\ell}} \delta_{\epsilon_{\ell}+1=n_{\ell}} = (1 - n_{\ell}) n_{\ell} \delta_{n_{\ell}-1=n_{\ell}} \delta_{\epsilon_{\ell}+1=n_{\ell}},
\]

we get

\[
\delta^{in} A = -i e \mathbf{E} \cdot \sum_{n,n'}^{t} \mathbf{J}_{\ell\ell'} A_{\ell\ell'} \left( -\hat{\rho}_{nN}^{(0)} \right) \frac{\hat{A}_{n'nN,nN}}{\epsilon_{\ell} - \epsilon_{\ell'} - i\hbar s} \left[ n_{\ell} \left( 1 - n_{\ell'} \right) - n_{\ell} \left( 1 - n_{\ell} \right) \right] = \sum_{\ell\ell'}^{t} C_{\ell\ell'}^{(0)} A_{\ell\ell'}, \tag{C44}
\]

where \( C_{\ell\ell'}^{(0)} = i e \mathbf{E} \cdot \mathbf{J}_{\ell\ell'} (f_{\ell}^{\ell'} - f_{\ell}^{\ell}). \) This is just the intrinsic contribution \( \delta^{in} A \equiv \sum_{\ell} A_{\ell}^{(0)} \delta^{in} A_{\ell} \) to linear response with respect to the uniform and time-independent electric field. Here we use \( \mathbf{v}_{\ell\ell'} \delta_{\ell\ell'} = -\frac{1}{\hbar} \left( \epsilon_{\ell} - \epsilon_{\ell'} \right) \mathbf{J}_{\ell\ell'} \) for \( \ell \neq \ell' \), and \( \delta^{in} A_{\ell} \) is just the intrinsic correction to \( A_{\ell} \) in the semiclassical Boltzmann formulation \[ \text{(52)} \]. In the case of \( A = j = e \mathbf{v}, \) \( \delta^{in} \mathbf{v}_{\ell} = \mathbf{v}_{\ell}^{bc} \) is the Berry-curvature anomalous velocity.

b. Side-jump velocity: scattering-induced interband-coherence

Now we analyze \( \delta^{3} A \). Here

\[
\sum_{nN,n'n'N',n''N''} \tilde{F}_{nN}^{(-2)} \frac{H_{nN,n'n'}^{n'n'N',nN} \hat{A}_{n'n'N',nN}}{(E_{nN} - E_{n'N'}) \left( E_{nN} - E_{n'N''} + i\hbar s \right)}
\]

\[
= \sum_{n,N',n''N'} \sum_{n,N''} \tilde{F}_{nN}^{(-2)} \sum_{\ell\ell'} \sum_{kk} \sum_{jji} H_{nN,\ell'}^{\ell',N',nN} \hat{A}_{n'n',nN} \left( a_{j}^\dagger a_{j'} \right)_{n',n''} \left( a_{k}^\dagger a_{k'} \right)_{n',n''},
\]

\[
\left( E_{nN} - E_{n'N'} - i\hbar s \right) \left( E_{nN} - E_{n'N''} + i\hbar s \right)
\]
since \( N' = N'' \) and then \( n' \neq n'' \) and thus \( j \neq j' \). Using

\[
(a^i_\ell a^j_\ell)_{n',n''} (a^i_\ell a^j_\ell)_{n',n''} = \delta_{\ell k} \delta_{j' k} \delta_{\ell \ell'} \delta_{n \ell} (1 - n_j) (1 - n_{j'}) \delta_{n_k - 1 = n''} \delta_{n_j + 1 = n'} \delta_{n_{j'} + 1 = n''} \delta_{n_j} \delta_{n_{j'}} \delta_{n_k} \delta_{n_{j''}}
\]

we get

\[
\sum_{n,N,n',N',n''} \tilde{P}^{(-2)}_{nN} \frac{\tilde{H}^{\prime}_{nN,n',N',nN'} \tilde{H}^{\prime}_{n',N''n',nN'} \tilde{A}^{n',n''}}{(E_{nN} - E_{n',N'}) \epsilon - i \hbar s} (E_{nN} - E_{n',N'} + i \hbar s)
\]

\[
= \sum_{n,N,N'} \sum_{n',N'} \tilde{P}^{(-2)}_{nN} \sum_{\ell j' j} \sum_{n,N,N'} p^{(0)}_{N} H^{\prime}_{\ell N,j' j,NN} H^{\prime}_{j' j,N',\ell N} A_{\ell j} n_{\ell} (1 - n_j) (1 - n_{j'}) \left( \frac{E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s}{(E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s)} \right) - \delta_{\ell j} \delta_{j' j} \delta_{\ell \ell'} \delta_{n j} (1 - n_{j'}) \delta_{n_{j'} + 1 = n'} \delta_{n' - 1 = n''} \delta_{n_j} \delta_{n_{j'}} \delta_{n_{j''}} \delta_{n_{j''}}.
\]

where we have applied the assumption \([C27]\). In the case of \( A = \nu, v_{j,j'} = \frac{1}{\hbar} r_{j,j'} (\epsilon_j - \epsilon_{j'}) \) thus

\[
\sum_{n,N,n',N',n''} \tilde{P}^{(-2)}_{nN} \frac{\tilde{H}^{\prime}_{nN,n',N',nN'} \tilde{H}^{\prime}_{n',N''n',nN'} \tilde{A}^{n',n''}}{(E_{nN} - E_{n',N'}) \epsilon - i \hbar s} (E_{nN} - E_{n',N'} + i \hbar s)
\]

\[
= 2 \Re \sum_{\ell j' j} \sum_{n,T} \tilde{P}^{(-2)}_{nN} (1 - n_j) \sum_{N,N'} p^{(0)}_{N} H^{\prime}_{\ell N,j' j,NN} H^{\prime}_{j' j,N',\ell N} E_{nN} \epsilon + \epsilon_j - \epsilon_{j'} - i \hbar s \left( \frac{E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s}{(E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s)} \right)
\]

\[
- 2 \Re \sum_{\ell j' j} \sum_{n,T} \tilde{P}^{(-2)}_{nN} (1 - n_j) \sum_{N,N'} p^{(0)}_{N} H^{\prime}_{\ell N,j' j,NN} H^{\prime}_{j' j,N',\ell N} E_{nN} \epsilon + \epsilon_j - \epsilon_{j'} - i \hbar s \left( \frac{E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s}{(E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s)} \right)
\]

The reason for writing the last term in this form will be clear soon. Thus we get

\[
\sum_{n,N,n',N',n''} \tilde{P}^{(-2)}_{nN} \frac{\tilde{H}^{\prime}_{nN,n',N',nN'} \tilde{H}^{\prime}_{n',N''n',nN'} \tilde{A}^{n',n''}}{(E_{nN} - E_{n',N'}) \epsilon - i \hbar s} (E_{nN} - E_{n',N'} + i \hbar s)
\]

\[
= 2 \Re \sum_{\ell j' j} \sum_{n,T} \tilde{P}^{(-2)}_{nN} (1 - n_j) \sum_{N,N'} p^{(0)}_{N} H^{\prime}_{\ell N,j' j,NN} H^{\prime}_{j' j,N',\ell N} E_{nN} \epsilon + \epsilon_j - \epsilon_{j'} - i \hbar s \left( \frac{E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s}{(E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s)} \right) + c.c.
\]

\[
- 2 \Re \sum_{\ell j' j} \sum_{n,T} \tilde{P}^{(-2)}_{nN} (1 - n_j) \sum_{N,N'} p^{(0)}_{N} H^{\prime}_{\ell N,j' j,NN} H^{\prime}_{j' j,N',\ell N} E_{nN} \epsilon + \epsilon_j - \epsilon_{j'} - i \hbar s \left( \frac{E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s}{(E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s)} \right) + c.c.
\]

Besides, we have

\[
\sum_{n,N,n',N',n''} \tilde{P}^{(-2)}_{nN} \left[ H^{\prime}_{nN,n',N',nN'} \tilde{A}^{n',n''} \right] \frac{E_{nN} - E_{n',N'} + i \hbar s}{(E_{nN} - E_{n',N'} + i \hbar s)} + c.c.
\]

\[
= \sum_{n,N} \sum_{N,N'} \tilde{P}^{(-2)}_{nN} \left[ \sum_{\ell j} H^{\prime}_{j N,j',N',NN} A_{\ell j} n_{\ell} (1 - n_j) (1 - n_{j'}) \right] \left( \frac{E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s}{(E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s)} + c.c. \right)
\]

\[
- \sum_{n,N} \sum_{N,N'} \tilde{P}^{(-2)}_{nN} \left[ \sum_{\ell j} H^{\prime}_{j N,j',N',NN} A_{\ell j} n_{\ell} (1 - n_j) n_{j'} \right] \left( \frac{E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s}{(E_{nN} - E_{n',N'} + \epsilon + \epsilon_j - \epsilon_{j'} + i \hbar s)} + c.c. \right).
\]
In the case of $A = \mathbf{v}$, \( v_{j'j} = \frac{1}{\pi \hbar} r_{j'j} (\epsilon_j - \epsilon_{j'}) \) thus

\[
\sum_{LL',LL''} \tilde{F}_L^{(-2)} \left[ \frac{\tilde{H}_L' \tilde{H}_L'' \tilde{A}_{LL'}}{(E_L - E_{L''} + i\hbar s)(E_L - E_{L'} + i\hbar s)} + \text{c.c.} \right] = -2 \Re \sum_{i,j,j'} \frac{i}{\hbar} \sum_{n} \tilde{F}_n^{(-2)} n_\ell (1 - n_j) \sum_{N,N'} P_N^{(0)} \frac{H_{NN,jN'}^i H_{jN'}'j'N'_{j''} j''}{E_N - E_{N'} + \epsilon_\ell - \epsilon_j - i\hbar s}
\]

\[
+ 2 \Re \sum_{i,j,j'} \frac{i}{\hbar} \sum_{n} \tilde{F}_n^{(-2)} n_\ell (1 - n_j) n_{j'} \sum_{N,N'} P_N^{(0)} \frac{H_{jN'}^{i}j'N'_{j''} j'' + r_{j'j} H_{jN'}^{i}j'N'_{j''} j''}{E_N - E_{N'} + \epsilon_\ell - \epsilon_j - i\hbar s}.
\]

Together with Eq. (C45), we obtain (the $D |\tilde{H}_j'N',\ell N|^2$ term is neglected as trivial renormalization effect, as in Ref. [52])

\[
\sum_{LL',LL''} \tilde{F}_L^{(-2)} \left[ \frac{\tilde{H}_L' \tilde{H}_L'' \tilde{A}_{LL'}}{(E_L - E_{L''} + i\hbar s)(E_L - E_{L'} + i\hbar s)} + \text{c.c.} \right] + \sum_{LL',LL''} \tilde{F}_L^{(-2)} \frac{H_{LL',LL''}'}{(E_L - E_{L'} + i\hbar s)(E_L - E_{L''} + i\hbar s)}
\]

\[
= -2 \Re \sum_{i} \frac{i}{\hbar} \sum_{n} \tilde{F}_n^{(-2)} n_\ell (1 - n_j) \sum_{N,N'} P_N^{(0)} \frac{2\pi}{\hbar} |H_{NN,jN'}^{i}|^2 \delta (E_N - E_{N'} + \epsilon_\ell - \epsilon_j) \left[ |iJ_j - iJ_j - D \arg H_{jN',\ell N}^i|^2 \right],
\]

which is equal to

\[
\sum_{n} \sum_{i,j,j'} \tilde{F}_n^{(-2)} n_\ell (1 - n_j) \sum_{N,N'} P_N^{(0)} \frac{2\pi}{\hbar} |H_{NN,jN'}^{i}|^2 \delta (E_N - E_{N'} + \epsilon_\ell - \epsilon_j) \left[ iJ_j - iJ_j - D \arg H_{jN',\ell N}^i \right] \]

\[
= \sum_{\ell} \tilde{f}_\ell^{(-2)} \left[ \sum_{e} \omega_{e\ell}^{(2)} \frac{1 - f_{\ell}^0}{1 - f_{e\ell}^0} \delta \mathbf{r}_{e\ell} \right].
\]

Here we used $\omega_{e\ell}^{(2)} = \sum_{N,N'} P_N^{(0)} \omega_{e'\ell'N',\ell'N}^{2\pi} = \frac{2\pi}{\hbar} \sum_{N,N'} P_N^{(0)} \left| H_{NN',\ell'N'}^{i} \right|^2 \delta (E_N - E_{N'} + \epsilon_\ell - \epsilon_{e'})$ and $\omega_{e\ell}^{(2)} f_{\ell}^0 \left( 1 - f_{e\ell}^0 \right) - \omega_{e\ell}^{(2)} f_{e\ell}^0 \left( 1 - f_{\ell}^0 \right) = 0$.

Summarizing, in the case of $A = \mathbf{v}$ we get

\[
\delta^{(3)} \mathbf{v} = \sum_{\ell} \tilde{f}_\ell \left( 1 - f_{\ell}^0 \right) \left( \sum_{e} \omega_{e\ell}^{(2)} \delta \mathbf{r}_{e\ell} \right) = \sum_{\ell} \tilde{f}_\ell^{(-2)} \left[ \sum_{e} \frac{1 - f_{\ell}^0}{1 - f_{e\ell}^0} \omega_{e\ell}^{(2)} \delta \mathbf{r}_{e\ell} \right],
\]

where we have used Eqs. (C28) and (C31) as well as the two statistical assumptions (C27) and (C29), and applied the techniques used in Appendix A of Ref. [52]. This result confirms our heuristic argument on the “proper definition” of the semiclassical side-jump velocity $\mathbf{v}_{\ell}^{(3)} = \sum_{e} \frac{1 - f_{\ell}^0}{1 - f_{e\ell}^0} \omega_{e\ell}^{(2)} \delta \mathbf{r}_{e\ell}$ in the case of dynamical disorder in the main text (note that $\omega_{e\ell}^{(2)} = w_{e\ell}$ and $\tilde{f}_\ell^{(-2)} = \delta f_{\ell}^0$).

Similar to the case of static disorder, the interband-coherence nature of $\mathbf{v}_{\ell}^{(3)}$ and thus that of the anomalous distribution function $g_{\ell}^0$ are not quite obvious when $\mathbf{v}_{\ell}^{(3)}$ is expressed in terms of $\delta \mathbf{r}_{e\ell}$. Therefore, in the following we provide some more information about scattering-induced interband-coherence response $\delta^{(3)} A$ when $A$ is not necessarily the current [40] [52]. In the following derivation the interband-coherence nature of $\mathbf{v}_{\ell}^{(3)}$ is apparent. In general cases of
\[ A, \text{ we have} \]
\[ \sum_{nN,n',N',n''N''} \tilde{F}^{(-2)}_{Nn} \frac{H''_{nN',n''nN}\tilde{A}_{n',n''}}{(E_{nN} - E_{n'N'} - \text{i} h\omega)(E_{nN} - E_{n''N''} + \text{i} h\omega)} \]
\[ = 2 \text{Re} \sum_{\ell j'j''} \sum_n \sum_{N,N'} \tilde{F}^{(-2)}_{nN} n_\ell (1 - n_j) \frac{H'_{\ell N,j'N'}A_{j'j''}H'_{j''N',\ell N}}{\epsilon_\ell - \epsilon_{j'} - \text{i} h\omega} \frac{1}{(E_{N'} - E_{N''} + \epsilon_\ell - \epsilon_{j''} - \text{i} h\omega)} \]
\[ - 2 \text{Re} \sum_{\ell j'j''} \sum_n \sum_{N,N'} \tilde{F}^{(-2)}_{nN} n_\ell (1 - n_j) \frac{H'_{\ell N,j'N'}A_{j'j''}H'_{j''N',\ell N}}{\epsilon_\ell - \epsilon_{j'} - \text{i} h\omega} \frac{1}{(E_{N'} - E_{N''} + \epsilon_\ell - \epsilon_{j''} - \text{i} h\omega)} \]
\[ + 2 \text{Re} \sum_{\ell j'j''} \sum_n \sum_{N,N'} \tilde{F}^{(-2)}_{nN} n_\ell n_{j'} \frac{H'_{\ell N,j'N'}H'_{j''N',j''N}A_{j'j''}}{\epsilon_\ell - \epsilon_{j'} - \text{i} h\omega} \frac{1}{(E_{N'} - E_{N''} + \epsilon_\ell - \epsilon_{j''} - \text{i} h\omega)} \]

and
\[ \sum_{nN,n',N',n''N''} \tilde{F}^{(-2)}_{nN} \left[ \frac{H''_{nN',n''nN}\tilde{A}_{n',n''}}{(E_{nN} - E_{n'N'} + \text{i} h\omega)(E_{nN} - E_{n''N''} + \text{i} h\omega)} + \text{c.c.} \right] \]
\[ = 2 \text{Re} \sum_{\ell j'j''} \sum_n \sum_{N,N'} \tilde{F}^{(-2)}_{nN} n_\ell (1 - n_j) \left( 1 - n_{j'} \right) \frac{H'_{\ell N,j'N'}H'_{j''N',\ell N}A_{j'j''}}{(\epsilon_\ell - \epsilon_{j'} - \text{i} h\omega)(E_{N'} - E_{N''} + \epsilon_\ell - \epsilon_{j''} - \text{i} h\omega)} \]
\[ - 2 \text{Re} \sum_{\ell j'j''} \sum_n \sum_{N,N'} \tilde{F}^{(-2)}_{nN} n_\ell (1 - n_j) n_{j'} \frac{H'_{\ell N,j'N'}H'_{j''N',\ell N}A_{j'j''}}{\epsilon_\ell - \epsilon_{j'} - \text{i} h\omega} \frac{1}{(E_{N'} - E_{N''} + \epsilon_\ell - \epsilon_{j''} - \text{i} h\omega)} \]

thus by some permutation of indices we get
\[ \delta^3 A = 2 \text{Re} \sum_{\ell j'j''} \sum_n \sum_{N,N'} \tilde{F}^{(-2)}_{nN} n_\ell (1 - n_j) \frac{1}{E_{N'} - E_{N''} + \epsilon_\ell - \epsilon_{j'} - \text{i} h\omega} \frac{H'_{\ell N,j'N'}}{\epsilon_\ell - \epsilon_{j'}} \frac{H'_{j''N',\ell N}A_{j'j''}}{\epsilon_\ell - \epsilon_{j''}} \]
\[ = 2 \text{Re} \sum_{\ell j'j''} \left[ (1 - f_\ell^0) \sum_{N,N'} P_{N'}^{(0)} + f_\ell^0 \sum_{N,N'} P_{N'}^{(0)} \right] \frac{H'_{\ell N,j'N'}}{E_{N'} - E_{N''} + \epsilon_\ell - \epsilon_{j'} - \text{i} h\omega} \frac{H'_{j''N',\ell N}A_{j'j''}}{\epsilon_\ell - \epsilon_{j''}} \frac{A_{j'j''}H'_{j''N',\ell N}}{\epsilon_\ell - \epsilon_{j'}}, \quad (C47) \]

i.e., \[ \delta^3 A = \sum \delta n^{(-2)} \delta^3 A_{\ell} \] with
\[ \delta^3 A_{\ell} = 2 \text{Re} \sum_{j'j''} \left[ (1 - f_\ell^0) \sum_{N,N'} P_{N'}^{(0)} + f_\ell^0 \sum_{N,N'} P_{N'}^{(0)} \right] \frac{H'_{\ell N,j'N'}}{E_{N'} - E_{N''} + \epsilon_\ell - \epsilon_{j'} - \text{i} h\omega} \frac{H'_{j''N',\ell N}A_{j'j''}}{\epsilon_\ell - \epsilon_{j''}} \frac{A_{j'j''}H'_{j''N',\ell N}}{\epsilon_\ell - \epsilon_{j'}} \]

(\text{C48})

From the interband matrix elements \[ A_{j'j''} \] and \[ A_{j'j''} \] (the momenta of the two states denoted by the subscripts are equal) one can see that the interband-coherence plays a role in both terms.

For static impurities, the state of the scattering system remains unchanged thus \[ N = N' \], and
\[ \sum_{N,N'} P_{N'}^{(0)} H'_{\ell N,j'N',\ell N} H'_{j''N',j'N'} = \sum_{N} P_{N}^{(0)} H'_{\ell N,j'N',\ell N} H'_{j''N',j'N} = \left< H'_{\ell \ell'} H'_{j'j''} \right> \]

(\text{C49})
is just the average over the disorder configurations. Therefore, after some algebra we obtain
\[ \delta^3 A = \sum_{\ell} \delta n^{(-2)} \left[ \sum_{j'j''} \left< H'_{\ell j'j''} \right> \frac{A_{j'j''}}{\epsilon_{j'} - \epsilon_{j''} - \text{i} h\omega} \right] + 2 \text{Re} \sum_{\ell \ell' \ell''} \left< H'_{\ell \ell'} H'_{\ell''} \right> A_{\ell \ell''} \]

(\text{C50})

which just reproduces the result obtained in the single-particle T-matrix formalism in the case of static disorder [10] [22].
Appendix D: Generalized Bloch-Boltzmann formalism from the Lyo-Holstein transport theory

The Lyo-Holstein theory [38, 42] takes into account the many-body effects in weakly-coupled electron-phonon systems. Lyo [38] split the electron coordinate operator into intra-cell and inter-cell parts and considered separately the resulting four components of the velocity-velocity correlation function. The theory thus contains some non-gauge-invariant quantities which are difficult to interpret. Partly because of these complications, the theory has not found wide applications. The main theoretical results of Lyo are his Eqs. (3.39) and (3.43). The latter representing the invariant quantities which are difficult to interpret. Partly because of these complications, the theory has not found wide applications. We focus on Lyo’s Eq. (3.39), which contains the contents of Lyo’s Eqs. (3.25) – (3.27), (3.37) and (3.38). We show that, Lyo’s Eq. (3.39) includes the intrinsic and side jump anomalous Hall conductivities. The proof of the equivalence are outlined as the following four steps:

(I) Lyo’s transport equation (3.27) is our Eq. (2b) in the main text for $g_\ell^a$, i.e., the conventional Bloch-Boltzmann equation.

(II) The opposite of the anomalous velocity defined by Lyo’s Eq. (3.26) is the last term of our side-jump velocity:

$$v_{\ell'}^{s,\text{Lyo}} = \sum_{\ell'} w_{\ell'\ell} \frac{1 - f^0_{\ell'}}{1 - f^0_\ell} \left( -\hat{D} \arg V_{\ell'} \right).$$  

Here $w_{\ell'\ell}$ is the electron-phonon scattering rate taking the same form as the lowest-Born-order expression in the density matrix approach, but with all the quantities renormalized by many-body effects (RPA-type renormalizations). For example, $w_{\ell'\ell}^{(2)}$ is proportional to $|V_{\ell'\ell}|^2$ with the renormalized electron-phonon coupling $V_{\ell'\ell}$. But Lyo’s anomalous velocity is not gauge invariant (under the gauge transformation $|u_\ell| \rightarrow e^{f^0_\ell}|u_\ell|$).

(III) Lyo’s transport equation (3.37) corresponds to our Eq. (11) in the main text for the anomalous distribution function $g_\ell^a$, but has a different form

$$\epsilon E \cdot v_{\ell'}^{s,\text{Lyo}} = -\sum_{\ell'} w_{\ell'\ell} \frac{1 - f^0_{\ell'}}{1 - f^0_\ell} \left( g_\ell^{a,\text{Lyo}} - g_{\ell'}^{a,\text{Lyo}} \right),$$

because Lyo defined his transport function as

$$g_\ell^{a,\text{Lyo}} = g_\ell^0 - \epsilon E \cdot A_\ell,$$

with $A_\ell$ the Berry connection. The so-defined transport function is not gauge invariant and not a real distribution function.

(IV) Combining (I) – (III), we recognize that Lyo’s Eqs. (3.25) and (3.38), whose sum gives his (3.39), take the following form in our notations:

$$(j^e)^{Lyo-sj(1)}_y = \epsilon \sum_{\ell} \left( -\epsilon f^0_{\ell} \right) g_\ell^{a,\text{Lyo}} \left( v_{\ell'}^{s,\text{Lyo}} \right)_y,$$

$$(j^e)^{Lyo-sj(2)}_y = \epsilon \sum_{\ell} \left( -\epsilon f^0_{\ell} \right) g_\ell^{a,\text{Lyo}} \left( v_{\ell'}^{0} \right)_y.$$  

Both of them are gauge dependent. But we show that the sum of them is gauge invariant. In fact we show

$$(j^e)^{sj(1)}_y = (j^e)^{Lyo-sj(1)}_y - \epsilon^2 E_x \sum_{\ell} \left( -\epsilon f^0_{\ell} \right) \left( A_\ell \right)_y \left( v_{\ell'}^{0} \right)_x,$$

and

$$(j^e)^{sj(2)}_y = (j^e)^{Lyo-sj(2)}_y + \epsilon^2 E_x \sum_{\ell} \left( -\epsilon f^0_{\ell} \right) \left( A_\ell \right)_x \left( v_{\ell'}^{0} \right)_y,$$

thus

$$(j^e)^{Lyo-sj(1)}_y + (j^e)^{Lyo-sj(2)}_y = (j^e)^{sj(1)}_y + (j^e)^{sj(2)}_y + (j^e)^{im}_y.$$  

\[D\]
As an example we provide the derivation of Eq. (D6):

\[
(j^e)^{y(1)} - (j^e)^{L_{y0}} = \sum_{\ell, \ell'} \left( - \frac{\partial f^0}{\partial \epsilon_\ell} \right) g^0_{\ell' \ell} \left( 1 - f^0(\epsilon_{\ell'}) \right) \left[ - \left( A_{y} \right)_{\ell} \right] + e \sum_{\ell, \ell'} \delta f^0_{\ell'} w_{\ell' \ell} \left( 1 - f^0(\epsilon_{\ell}) \right) \left( A_{y} \right)_{\ell}
\]

\[
= e \sum_{\ell} \left( - \frac{\partial f^0}{\partial \epsilon_\ell} \right) (A_{y})_{\ell} \sum_{\ell'} w_{\ell' \ell} \left( 1 - f^0(\epsilon_{\ell'}) \right) \left[ g^0_{\ell'} - g^0_{\ell} \right]
\]

\[
= -e^2 E_x \sum_{\ell} \left( - \frac{\partial f^0}{\partial \epsilon_\ell} \right) (A_{y})_{\ell} \left( v_{\ell} \right)_{x}^2.
\]

where the interchange of \( \ell \) and \( \ell' \) is used in the first step and the conventional Bloch-Boltzmann equation of the main text is used in the last step.
