Abstract

The sum secure degrees of freedom (s.d.o.f.) of two fundamental multi-user network structures, the $K$-user Gaussian multiple access (MAC) wiretap channel and the $K$-user interference channel (IC) with secrecy constraints, have been determined recently as $\frac{K(K-1)}{K(K-1)+1}$ [1,2] and $\frac{K(K-1)}{2K-1}$ [3,4], respectively. In this paper, we determine the entire s.d.o.f. regions of these two channel models. The converse for the MAC follows from a middle step in the converse of [1,2]. The converse for the IC includes constraints both due to secrecy as well as due to interference. Although the portion of the region close to the optimum sum s.d.o.f. point is governed by the upper bounds due to secrecy constraints, the other portions of the region are governed by the upper bounds due to interference constraints. Different from the existing literature, in order to fully understand the characterization of the s.d.o.f. region of the IC, one has to study the 4-user case, i.e., the 2 or 3-user cases do not illustrate the generality of the problem. In order to prove the achievability, we use the polytope structure of the converse region.

In both MAC and IC cases, we develop explicit schemes that achieve the extreme points of the polytope region given by the converse. Specifically, the extreme points of the MAC region are achieved by an $m$-user MAC wiretap channel with $K-m$ helpers, i.e., by setting $K-m$ users’ secure rates to zero and utilizing them as pure (structured) cooperative jammers. The extreme points of the IC region are achieved by a $(K-m)$-user IC with confidential messages, $m$ helpers, and $N$ external eavesdroppers, for $m \geq 1$ and a finite $N$. A byproduct of our results in this paper is that the sum s.d.o.f. is achieved only at one extreme point of the s.d.o.f. region, which is the symmetric-rate extreme point, for both MAC and IC channel models.
1 Introduction

In this paper, we consider two fundamental multi-user network structures under secrecy constraints: $K$-user multiple access channel (MAC) and $K$-user interference channel (IC). Information-theoretic security of communication was first considered by Shannon in [5] via a noiseless wiretap channel. Noisy wiretap channel was introduced by Wyner who showed that information-theoretically secure communication was possible if the eavesdropper was degraded with respect to the legitimate receiver [6]. Csiszar and Korner generalized Wyner’s result to arbitrary, not necessarily degraded, wiretap channels, and showed that information-theoretically secure communication was possible even when the eavesdropper was not degraded [7]. Leung-Yan-Cheong and Hellman extended Wyner’s setting to a Gaussian channel, which is degraded [8]. This line of research has been extended to many multi-user scenarios, for both general and Gaussian channel models, see e.g., [9–30]. The secrecy capacity regions of most of these multi-user channels remain open problems even in simple Gaussian settings.

In the absence of exact secrecy capacity regions, the behaviour of the secrecy rates at high signal-to-noise ratio (SNR) regimes have been studied by focusing on the secure degrees of freedom (s.d.o.f.), which is the pre-log of the secrecy rates, in [1–4, 31–45]. In this paper, we focus on the $K$-user Gaussian MAC wiretap channel and the $K$-user Gaussian IC with secrecy constraints. The secrecy capacity regions of both of these models remain open. The sum s.d.o.f. of both of these models have been determined recently as $K(K-1)\frac{K(K-1)}{2K-1}$ [1–2] and $K(K-1)\frac{K(K-1)}{2K-1}$ [3,4], respectively. In this paper, we determine the entire s.d.o.f. regions of these channel models.

We start with the MAC wiretap channel, where multiple legitimate transmitters wish to have secure communication with a legitimate receiver in the presence of an eavesdropper; see Figure 1. The converse for the sum s.d.o.f. is developed in [1,2] using two lemmas: the secrecy penalty lemma and the role of a helper lemma, which, respectively, quantify the rate penalty due to the existence of an eavesdropper, and quantify the impact of a helper (interferer) on the rate of another legitimate transmitter. The achievability for the sum s.d.o.f. in [1,2] is based on real interference alignment [46,47] and structured cooperative jamming [18] with an emphasis on simultaneous alignments at both the legitimate receiver and the eavesdropper. We develop the converse for the entire region by starting from a middle step in the converse proof of [1,2]. While [1,2] developed asymmetric upper bounds for the secure rates, since the sum s.d.o.f. was achieved by symmetric rates, [1,2] summed up the asymmetric upper bounds to get a single symmetric upper bound to match the achievability. We revisit the converse proof in [1,2] and develop a converse for the entire region by keeping the developed asymmetric upper bounds. Therefore, the converse proofs developed in [1,2] to obtain a converse for the sum s.d.o.f. suffice to obtain a tight converse for the entire region.

The converse region for the s.d.o.f. problem has a general polytope structure, as opposed to the non-secrecy counterpart for the MAC which has a polymatroid structure [18]. Polytope is a bounded polyhedron, which is an intersection of a finite number of half-spaces. Such
definition is called a half-space representation, which is exactly the way our converse is expressed. In order to show the achievability of the polytope region, we need to show the achievability of boundaries of all of the half-spaces, which is inefficient. We use Minkowski theorem [49, Theorem 2.4.5] which states that the polytope region discussed in this paper can be represented by the convex hull of all of its extreme points, which there are only finitely many. We, therefore, first determine the extreme points of this converse (polytope) region, and then develop an achievable scheme for each extreme point of the converse region; the achievability of the entire region then follows from time-sharing. In particular, each extreme point of the converse region is achieved by an $m$-user MAC wiretap channel with $K - m$ helpers, for $m = 1, \ldots, K$, i.e., by setting $K - m$ users’ secure rates to zero and utilizing them as pure (structured) cooperative jammers.

We then consider the IC with secrecy constraints; see Figure 2. In particular, we consider three different secrecy constraints in a unified framework as in [3,4]: 1) $K$-user IC with one external eavesdropper (IC-EE), where $K$ transmitter-receiver pairs wish to have secure communication against an external eavesdropper. 2) $K$-user IC with confidential messages (IC-CM), where there are no external eavesdroppers, but each transmitter-receiver pair wishes to secure its communication against the remaining $K - 1$ receivers. 3) $K$-user IC with confidential messages and one external eavesdropper (IC-CM-EE), which is a combination of the previous two cases, where each transmitter-receiver pair wishes to secure its communication against the $K - 1$ receivers and the external eavesdropper. The converse for the sum s.d.o.f. (the sum s.d.o.f. is the same for all three models) was developed in [3,4] by using the secrecy penalty lemma and the role of a helper lemma in a certain way, and then by summing up the obtained asymmetric upper bounds into a single symmetric upper bound. The achievability for the sum s.d.o.f. in [3,4] is based on asymptotical real interference alignment [46] to enable simultaneous alignment at multiple receivers.

In order to develop a converse for the entire region for the IC case, similar to the MAC
Figure 2: $K$-user interference channel (IC) with secrecy constraints.

case, we start by re-examining the converse proof in [3,4] for the sum s.d.o.f. However, unlike the MAC case, the original steps used for the sum s.d.o.f. are not tight for the characterization of the entire region. There are two reasons for this: First, in the case of the MAC wiretap channel, since there is a single legitimate receiver, each transmitter (helper/interferer) impacts the total rate of all other legitimate transmitters at the legitimate receiver, and therefore, there is a single manner in which the role of a helper lemma is applied. In the IC case, there are many different ways in which the role of a helper lemma can be invoked as there are multiple receivers. In this case, by pairing up helpers (interferers) and the receivers we obtain $(K-1)^K$ upper bounds; even after removing the redundancies, we get $\binom{K}{K-1} = \binom{2K-2}{K-1}$ upper bounds. In order to obtain the tightest subset of these upper bounds, we choose the most binding pairing of the helpers/interferers and the receivers. In particular, we do not apply the next one (i.e., $k = i - 1$ and $k = i + 1$) selection of helpers/interferers as we have done in [3, Eqns. (24) and (45)]. Instead, we choose all of the transmitters as interfering with a single transmitter-receiver pair; see (112) and (128) in this paper. This yields the tightest upper bounds. Second, we observe that, when we study the s.d.o.f. region, we need to consider the non-secrecy upper bounds for the underlying IC [50,51] as additional upper bounds. We note that such upper bounds are not binding for the case of MAC wiretap channel s.d.o.f. region, or the MAC and IC sum s.d.o.f. converses. In fact, such non-secrecy upper bounds for the IC are not binding even for the cases of $K = 2$ or $K = 3$. We observe that these upper bounds are needed for the IC with secrecy constraints starting with $K \geq 4$. To the best of our knowledge, this is the first time in network information theory that $K = 2$ or $K = 3$ do not capture the most generality of the problem, and we need to study $K = 4$ to observe a certain multi-user phenomenon to take effect.

The converse region for the IC with secrecy constraints has a polytope structure as well, and similar to the MAC wiretap channel case, we need to determine the extreme points of this polytope region. However, different from the MAC wiretap channel case, the converse region consists of two classes of upper bounds, due to secrecy and due to interference. This makes it difficult to identify the extreme points of the converse polytope. Finding the extreme points is related to finding full-rank sub-matrices from an overall matrix of size
Since there are approximately \( K^K \) such matrices, an exhaustive search is intractable, and therefore we investigate the consistency of the upper bounds, which reduces the possible number of sub-matrices to examine. After determining the extreme points of the converse polytope, we develop an achievable scheme for each extreme point. In particular, each extreme point of the converse region is achieved by a \((K - m)\)-user IC-CM with \( m \) helpers and \( N \) independent external eavesdroppers, for \( m \geq 1 \) and finite \( N \).

Finally, after characterizing the entire s.d.o.f. regions of the MAC and IC with secrecy constraints, as a byproduct of our results in this paper, we note that the sum s.d.o.f. is achieved only at one extreme point of the s.d.o.f. region, which is the symmetric-rate extreme point, for both MAC and IC channel models.

## 2 System Model, Definitions and the Result

### 2.1 \( K \)-user Gaussian MAC Wiretap Channel

The \( K \)-user Gaussian MAC wiretap channel (see Figure 1) is:

\[
Y_1 = \sum_{i=1}^{K} h_i X_i + N_1
\]

\[
Y_2 = \sum_{i=1}^{K} g_i X_i + N_2
\]

where \( Y_1 \) is the channel output of the legitimate receiver, \( Y_2 \) is the channel output of the eavesdropper, \( X_i \) is the channel input of transmitter \( i \), \( h_i \) and \( g_i \) are the channel gains of transmitter \( i \) to the legitimate receiver and the eavesdropper, respectively, and \( N_1 \) and \( N_2 \) are independent Gaussian random variables with zero-mean and unit-variance. All the channel gains are independently drawn from continuous distributions, and are time-invariant throughout the communication session. We further assume that all \( h_i \) and \( g_i \) are non-zero. All channel inputs satisfy average power constraints, \( \mathbb{E}[X_i^2] \leq P \), for \( i = 1, \ldots, K \).

Each transmitter \( i \) has a message \( W_i \) intended for the legitimate receiver. For each \( i \), message \( W_i \) is uniformly and independently chosen from set \( \mathcal{W}_i \). The rate of message \( i \) is \( R_i \overset{\Delta}{=} \frac{1}{n} \log |\mathcal{W}_i| \). Transmitter \( i \) uses a stochastic function \( f_i: \mathcal{W}_i \to \mathbf{X}_i \), where the \( n \)-length vector \( \mathbf{X}_i \overset{\Delta}{=} X_i^n \) denotes the \( i \)th user’s channel input in \( n \) channel uses. All messages are needed to be kept secret from the eavesdropper. A secrecy rate tuple \((R_1, \ldots, R_K)\) is said to be achievable if for any \( \epsilon > 0 \) there exist \( n \)-length codes such that the legitimate receiver can decode the messages reliably, i.e., the probability of decoding error is less than \( \epsilon \)

\[
\Pr\left[(W_1, \ldots, W_K) \neq (\hat{W}_1, \ldots, \hat{W}_K)\right] \leq \epsilon
\]
and the messages are kept information-theoretically secure against the eavesdropper

$$\frac{1}{n} H(W_1, \ldots, W_K | Y_2) \geq \frac{1}{n} H(W_1, \ldots, W_K) - \epsilon$$ \hspace{1cm} (4)$$

where $\hat{W}_1, \ldots, \hat{W}_K$ are the estimates of the messages based on observation $Y_1$, where $Y_1 \triangleq Y_1^n$ and $Y_2 \triangleq Y_2^n$.

The s.d.o.f. region is defined as:

$$D = \left\{ d : (R_1, \ldots, R_K) \text{ is achievable and } d_i \triangleq \lim_{P \to \infty} \frac{R_i}{\frac{1}{2} \log P}, \ i = 1, \ldots, K \right\}$$ \hspace{1cm} (5)$$

The sum s.d.o.f. is defined as:

$$D_{s, \Sigma} \triangleq \lim_{P \to \infty} \sup \sum_{i=1}^{K} R_i \frac{1}{\frac{1}{2} \log P}$$ \hspace{1cm} (6)$$

where the supremum is over all achievable secrecy rate tuples $(R_1, \ldots, R_K)$. The sum s.d.o.f. of the $K$-user Gaussian MAC wiretap channel is characterized in the following theorem.

**Theorem 1** ([1, Theorem 1]) *The sum s.d.o.f. of the $K$-user Gaussian MAC wiretap channel is $rac{K(K-1)}{K(K-1)+1}$ for almost all channel gains.*

In this paper, we characterize the s.d.o.f. region of the $K$-user Gaussian MAC wiretap channel in the following theorem.

**Theorem 2** *The s.d.o.f. region $D$ of the $K$-user Gaussian MAC wiretap channel is the set of all $d$ satisfying

\[
K d_i + (K - 1) \sum_{j=1, j \neq i}^{K} d_j \leq K - 1, \quad i = 1, \ldots, K
\]

\[
d_i \geq 0, \quad i = 1, \ldots, K
\]

for almost all channel gains.*
2.2 $K$-user Gaussian IC with Secrecy Constraints

The $K$-user Gaussian IC with secrecy constraints (see Figure 2) is:

\[ Y_i = \sum_{j=1}^{K} h_{ji}X_j + N_i, \quad i = 1, \ldots, K \]  
\[ Z = \sum_{j=1}^{K} g_jX_j + N_Z \]

where $Y_i$ is the channel output of receiver $i$, $Z$ is the channel output of the external eavesdropper (if there is any), $X_i$ is the channel input of transmitter $i$, $h_{ji}$ is the channel gain of the $j$th transmitter to the $i$th receiver, $g_j$ is the channel gain of the $j$th transmitter to the eavesdropper (if there is any), and $\{N_1, \ldots, N_K, N_Z\}$ are mutually independent zero-mean unit-variance Gaussian random variables. All the channel gains are independently drawn from continuous distributions, and are time-invariant throughout the communication session. We further assume that all $h_{ji}$ are non-zero, and all $g_j$ are non-zero if there is an external eavesdropper. All channel inputs satisfy average power constraints, $E [X_i^2] \leq P$, for $i = 1, \ldots, K$.

Each transmitter $i$ intends to send a message $W_i$, uniformly chosen from a set $\mathcal{W}_i$, to receiver $i$. The rate of message $i$ is $R_i \triangleq \frac{1}{n} \log |\mathcal{W}_i|$, where $n$ is the number of channel uses. Transmitter $i$ uses a stochastic function $f_i : \mathcal{W}_i \rightarrow X_i$ to encode the message, where $X_i \sim X_i^n$ is the $n$-length channel input of user $i$. The legitimate receiver $j$ decodes the message as $\hat{W}_j$ based on its observation $Y_j$. A secrecy rate tuple $(R_1, \ldots, R_K)$ is said to be achievable if for any $\epsilon > 0$, there exist joint $n$-length codes such that each receiver $j$ can decode the corresponding message reliably, i.e., the probability of decoding error is less than $\epsilon$ for all messages,

\[ \max_j \Pr \left[ W_j \neq \hat{W}_j \right] \leq \epsilon \]  

and the corresponding secrecy requirement is satisfied. We consider three different secrecy requirements:

1) In IC-EE, Figure 3(a), all of the messages are kept information-theoretically secure against the external eavesdropper,

\[ \frac{1}{n} H(W_1, \ldots, W_K | Z) \geq \frac{1}{n} H(W_1, \ldots, W_K) - \epsilon \]  

2) In IC-CM, Figure 3(b), all unintended messages are kept information-theoretically secure against each receiver,

\[ \frac{1}{n} H(W^K_{-i} | Y_i) \geq \frac{1}{n} H(W^K_{-i}) - \epsilon, \quad i = 1, \ldots, K \]
Figure 3: The receiver sides of the three channel models: (a) $K$-user IC-EE, (b) $K$-user IC-CM, and (c) $K$-user IC-CM-EE, where $W_{K−i} \triangleq \{W_1, \ldots, W_{i−1}, W_{i+1}, \ldots, W_K\}$.

where $W_{K−i} \triangleq \{W_1, \ldots, W_{i−1}, W_{i+1}, \ldots, W_K\}$.

3) In IC-CM-EE, Figure 3(c), all of the messages are kept information-theoretically secure against both the $K−1$ unintended receivers and the eavesdropper, i.e., we impose both secrecy constraints in (12) and (13).

The s.d.o.f. region and the sum s.d.o.f. are defined as in (5) and (6). The sum s.d.o.f. of the $K$-user IC-EE, IC-CM, and IC-CM-EE is characterized in the following theorem.

**Theorem 3 ([3, Theorem 1])** The sum s.d.o.f. of the $K$-user Gaussian IC-EE, IC-CM, and IC-CM-EE is $\frac{K(K−1)}{2(K−1)}$ for almost all channel gains.

In this paper, we characterize the s.d.o.f. region of the $K$-user IC-EE, IC-CM, and IC-CM-EE in the following theorem.

**Theorem 4** The s.d.o.f. region $D$ of $K$-user IC-EE, IC-CM, and IC-CM-EE is the set of all $d$ satisfying

$$Kd_i + \sum_{j=1, j \neq i}^{K} d_j \leq K−1, \quad i = 1, \ldots, K$$

(14)

$$\sum_{i \in V} d_i \leq 1, \quad \forall V \subseteq \{1, \ldots, K\}, \quad |V| = 2$$

(15)

$$d_i \geq 0, \quad i = 1, \ldots, K$$

(16)

for almost all channel gains.
3 Preliminaries

3.1 Polytope Structure and Extreme Points

Let \( X \subseteq \mathbb{R}^n \). The convex hull of \( X \), \( \text{Co}(X) \), is the set of all convex combinations of the points in \( X \):

\[
\text{Co}(X) \triangleq \left\{ \sum_i \lambda_i x_i \mid x_i \in X, \sum_i \lambda_i = 1, \lambda_i \in \mathbb{R}, \lambda_i \geq 0, \forall i \right\}
\]

(17)

A set \( P \subseteq \mathbb{R}^n \) is a polyhedron if there is a system of finitely many inequalities \( Hx \leq h \) such that

\[
P = \{ x \in \mathbb{R}^n \mid Hx \leq h \}
\]

(18)

A set \( P \subseteq \mathbb{R}^n \) is a polytope if there is a finite set \( X \subseteq \mathbb{R}^n \) such that \( P = \text{Co}(X) \). Then, we have the following theorem.

**Theorem 5 ([49, Theorem 3.1.3])** Let \( P \subseteq \mathbb{R}^n \). Then, \( P \) is a bounded polyhedron if only if \( P \) is a polytope.

Therefore, if \( P \subseteq \mathbb{R}^n \) is a polytope, then it is a convex hull of some finite set \( X \). By the properties of the convex hull of a finite set \( X \), \( P \) is a bounded, closed, convex set. Since \( P \) is a subset of the Euclidean space, \( P \) is a compact convex set. An extreme point is formally defined as follows.

**Definition 1 (Extreme point)** Let \( P \subseteq \mathbb{R}^n \). An \( x \in P \) is an extreme point if there are no \( y, z \in P \setminus \{x\} \) such that \( x = \lambda y + (1 - \lambda)z \) for any \( \lambda \in (0, 1) \). Then, \( \text{Ex}(P) \) is the set of all extreme points of \( P \).

**Theorem 6 (Minkowski, 1910. [49, Theorem 2.4.5])** Let \( P \subseteq \mathbb{R}^n \) be a compact convex set. Then,

\[
P = \text{Co}(\text{Ex}(P)).
\]

(19)

Minkowski theorem plays an important role in this paper, since it tells that, instead of studying the polytope \( P \) itself, for certain problems, e.g., achievability proofs, we can simply concentrate on all extreme points \( \text{Ex}(P) \). Finally, the following theorem helps us find all extreme points of a polytope \( P \) efficiently: We select any \( n \) linearly independent active/tight boundaries and check whether they give a point in the polytope \( P \).

**Theorem 7 ([52, Theorem 7.2(b)])** \( x \in \mathbb{R}^n \) is an extreme point of polyhedron \( P(H, h) \) if and only if \( Hx \leq h \) and \( H'x = h' \) for some \( n \times (n + 1) \) sub-matrix \( (H', h') \) of \( (H, h) \) with \( \text{rank}(H') = n \).
3.2 Real Interference Alignment

In this subsection, we review pulse amplitude modulation (PAM) and real interference alignment [46, 47], similar to the review in [39, Section III]. The purpose of this subsection is to illustrate that by using real interference alignment, the transmission rate of a PAM scheme can be made to approach the Shannon achievable rate at high SNR. This provides a universal and convenient way to design capacity-achieving signalling schemes at high SNR by using PAM for different channel models as will be done in later sections.

3.2.1 Pulse Amplitude Modulation

For a point-to-point scalar Gaussian channel,

\[ Y = X + Z \]  \hspace{1cm} (20)

with additive Gaussian noise \( Z \) of zero-mean and variance \( \sigma^2 \), and an input power constraint \( \mathbb{E}[X^2] \leq P \), assume that the input symbols are drawn from a PAM constellation,

\[ C(a, Q) = a \{-Q, -Q + 1, \ldots, Q - 1, Q\} \]  \hspace{1cm} (21)

where \( Q \) is a positive integer and \( a \) is a real number to normalize the transmit power. Note that, \( a \) is also the minimum distance \( d_{\text{min}}(C) \) of this constellation, which has the probability of error

\[ \Pr(e) = \Pr[X \neq \hat{X}] \leq \exp \left(-\frac{d_{\text{min}}^2}{8\sigma^2}\right) = \exp \left(-\frac{a^2}{8\sigma^2}\right) \]  \hspace{1cm} (22)

where \( \hat{X} \) is an estimate for \( X \) obtained by choosing the closest point in the constellation \( C(a, Q) \) based on observation \( Y \).

The transmission rate of this PAM scheme is

\[ R = \log(2Q + 1) \]  \hspace{1cm} (23)

since there are \( 2Q + 1 \) signalling points in the constellation. For any small enough \( \delta > 0 \), if we choose \( Q = P^{1-\delta} \) and \( a = \gamma P^{\delta/2} \), where \( \gamma \) is a constant independent of \( P \), then

\[ \Pr(e) \leq \exp \left(-\frac{\gamma^2 P^\delta}{8\sigma^2}\right) \quad \text{and} \quad R \geq \frac{1 - \delta}{2} \log P \]  \hspace{1cm} (24)

and we can have \( \Pr(e) \to 0 \) and \( R \to \frac{1}{2} \log P \) as \( P \to \infty \). That is, we can have reliable communication at rates approaching \( \frac{1}{2} \log P \).

Note that the PAM scheme has small probability of error (i.e., reliability) only when \( P \) goes to infinity. For arbitrary \( P \), the probability of error \( \Pr(e) \) is a finite number. Similar to the steps in [46,53], we connect the PAM transmission rate to the Shannon rate in the
following derivation. We note that Shannon rate of $I(X; Y)$ is achievable with arbitrary reliability using a random codebook:

$$R' = I(X; Y)$$  \hfill (25)
$$\geq I(X; \hat{X})$$  \hfill (26)
$$= H(X) - H(X|\hat{X})$$  \hfill (27)
$$= \log(2Q + 1) - H(X|\hat{X})$$  \hfill (28)
$$\geq \log(2Q + 1) - 1 - \Pr(e) \log(2Q + 1)$$  \hfill (29)
$$\geq \left[ 1 - \Pr(e) \right] \frac{1 - \delta}{2} \log P - 1$$  \hfill (30)

where we use the Markov chain $X \to Y \to \hat{X}$ and bound $H(X|\hat{X})$ using Fano’s inequality. Therefore, we can achieve the rate in (30) with arbitrary reliability, where for any fixed $P$, $\Pr(e)$ in (30) is the probability of error of the PAM scheme given in (24), which is a well-defined function of $P$. For a finite $P$, while $\Pr(e)$ may not be arbitrarily small, the rate achieved in (30), which is smaller than the rate of PAM in (23), is achieved arbitrarily reliably. We finally note that as $P$ goes to infinity $\Pr(e)$ goes to zero exponentially, and from (30), both PAM transmission rate and the Shannon achievable rate have the same asymptotical performance, i.e., PAM transmission rate has 1 Shannon d.o.f.

### 3.2.2 Real Interference Alignment

This PAM scheme for the point-to-point scalar channel can be generalized to multiple data streams. Let the transmit signal be

$$x = a^T b = \sum_{i=1}^{L} a_i b_i$$  \hfill (31)

where $a_1, \ldots, a_L$ are rationally independent real numbers\footnote{$a_1, \ldots, a_L$ are rationally independent if whenever $q_1, \ldots, q_L$ are rational numbers then $\sum_{i=1}^{L} q_i a_i = 0$ implies $q_i = 0$ for all $i$.} and each $b_i$ is drawn independently from the constellation $C(a, Q)$ in (21). The real value $x$ is a combination of $L$ data streams, and the constellation observed at the receiver consists of $(2Q + 1)^L$ signal points.

By using the Khintchine-Groshev theorem of Diophantine approximation in number theory, \cite{46,47} bounded the minimum distance $d_{\text{min}}$ of points in the receiver’s constellation: For any $\delta > 0$, there exists a constant $k_\delta$, such that

$$d_{\text{min}} \geq \frac{k_\delta a}{Q^L - 1 + \delta}$$  \hfill (32)

for almost all rationally independent $\{a_i\}_{i=1}^{L}$, except for a set of Lebesgue measure zero. Since
the minimum distance of the receiver constellation is lower bounded, with proper choice of a and Q, the probability of error can be made arbitrarily small, with rate R approaching \( \frac{1}{2} \log P \). This result is stated in the following lemma, as in [39, Proposition 3].

**Lemma 1 ([46,47])** For any small enough \( \delta > 0 \), there exists a positive constant \( \gamma \), which is independent of \( P \), such that if we choose

\[
Q = P^{\frac{1}{2(\delta + \delta)}} \quad \text{and} \quad a = \gamma P^{\frac{1}{2}} Q
\]

then the average power constraint is satisfied, i.e., \( E[X^2] \leq P \), and for almost all \( \{a_i\}_{i=1}^{L} \), except for a set of Lebesgue measure zero, the probability of error is bounded by

\[
\Pr(e) \leq \exp \left( -\eta_{\gamma} P^{\delta} \right)
\]

where \( \eta_{\gamma} \) is a positive constant which is independent of \( P \).

Furthermore, as a simple extension, if \( b_i \) are sampled independently from different constellations \( C_i(a, Q_i) \), the lower bound in (32) can be modified as

\[
d_{\text{min}} \geq \frac{k_\delta a}{(\max_i Q_i)^{L-1+\delta}}
\]

### 4 S.d.o.f. Region of K-User MAC Wiretap Channel

In this section, we study the \( K \)-user MAC wiretap channel defined in Section 2.1 and prove the s.d.o.f. region stated in Theorem 2. We first illustrate the regions for \( K = 2 \) and \( K = 3 \) cases as examples. We then provide the converse in Section 4.1, investigate the converse region in terms of its extreme points in Section 4.2 and show the achievability of each extreme point in Section 4.3.

For \( K = 2 \), the s.d.o.f. region in Theorem 2 becomes

\[
D = \left\{ d : 2d_1 + d_2 \leq 1, \\
d_1 + 2d_2 \leq 1, \\
d_1, d_2 \geq 0 \right\}
\]

and is shown in Figure 4. The extreme points of this region are: \( (0, 0), (\frac{1}{2}, 0), (0, \frac{1}{2}), \) and \( (\frac{1}{3}, \frac{1}{3}) \). In order to provide the achievability of the region, it suffices to provide the achievability of these extreme points. In fact the achievabilities of \( (\frac{1}{2}, 0), (0, \frac{1}{2}) \) were proved in [40] in the helper setting and the achievability of \( (\frac{1}{3}, \frac{1}{3}) \) was proved in [1][2]. Note that \( (\frac{1}{3}, \frac{1}{3}) \) is the only sum s.d.o.f. optimum point.
Figure 4: The s.d.o.f. region of the $K = 2$-user MAC wiretap channel.

For $K = 3$, the s.d.o.f. region in Theorem 2 becomes

$$D = \left\{ \mathbf{d} : \begin{array}{l} 3d_1 + 2d_2 + 2d_3 \leq 2, \\ 2d_1 + 3d_2 + 2d_3 \leq 2, \\ 2d_1 + 2d_2 + 3d_3 \leq 2, \\ d_1, d_2, d_3 \geq 0 \end{array} \right\}$$

and is shown in Figure 5. The extreme points of this region are:

$$(0, 0, 0), \left(\frac{2}{3}, 0, 0\right), \left(0, \frac{2}{3}, 0\right), \left(0, 0, \frac{2}{3}\right), \left(\frac{2}{5}, \frac{2}{5}, 0\right), \left(\frac{2}{5}, 0, \frac{2}{5}\right), \left(0, \frac{2}{5}, \frac{2}{5}\right), \left(\frac{2}{7}, \frac{2}{7}, \frac{2}{7}\right)$$

which correspond to the maximum individual s.d.o.f. (see Gaussian wiretap channel with two helpers [40]), the maximum sum of pair of s.d.o.f. (see two-user Gaussian MAC wiretap channel with one helper, proved in Section 4.3), and the maximum sum s.d.o.f. (see three-user Gaussian MAC wiretap channel [1][2]). Note that $\left(\frac{2}{7}, \frac{2}{7}, \frac{2}{7}\right)$ is the only sum s.d.o.f. optimum.
Figure 5: The s.d.o.f. region of the $K = 3$-user MAC wiretap channel.

4.1 Converse

The converse simply follows from a key inequality in the proof in [1]. We re-examine [1, Eqn. (41)]:

$$nR_i + (K - 1) \sum_{j=1}^{K} nR_j \leq (K - 1) h(Y_1) + nc_i, \quad i = 1, \ldots, K$$

(39)

where all $\{c_i\}$ in this paper are constants independent of $P$.

Clearly, (39) is not symmetric. However, the lower bound derived in [1] was achieved by a symmetric scheme. Therefore, in [1], in order to obtain a matching upper bound, we
summed up \((39)\) for all \(i\) to obtain:

\[
[K(K-1)+1] \sum_{j=1}^{K} nR_j \leq K(K-1)h(Y_1) + nc' \\
\leq K(K-1)\frac{n}{2} \log P + nc''
\] (41)

which provided the desired upper bound for the sum s.d.o.f.

\[
D_{s,\Sigma} \leq \frac{K(K-1)}{K(K-1)+1}
\] (42)

which is the converse for Theorem 1.

In fact, \((39)\) provides more information than what is needed for the sum s.d.o.f. only. In this paper, we start from \((39)\)

\[
nR_i + (K-1) \sum_{j=1}^{K} nR_j \leq (K-1)\left(\frac{n}{2} \log P\right) + nc_i, \quad i = 1, \ldots, K
\] (43)

divide by \(\frac{n}{2} \log P\) and take the limit \(P \to \infty\) on both sides to obtain,

\[
d_i + (K-1) \sum_{j=1}^{K} d_j \leq K-1, \quad i = 1, \ldots, K
\] (44)

that is,

\[
Kd_i + (K-1) \sum_{j=1,j\neq i}^{K} d_j \leq K-1, \quad i = 1, \ldots, K
\] (45)

which concludes the converse proof of Theorem 2.

4.2 Polytope Structure and Extreme Points

To prove that the region \(D\) in Theorem 2 is tight (i.e., achievable), we first express it in terms of its extreme points, explicitly characterize all of its extreme points, and develop a scheme to achieve each of its extreme points.

The region in Theorem 2 is a polytope, which is a convex hull of some finite set \(X\), as discussed in Section 3.1. By the properties of the convex hull of a finite set \(X\), \(D\) is a bounded, closed, convex set. Since \(D \subset R^K\), \(D\) is a compact convex set. From Minkowski theorem, the polytope \(D\) in Theorem 2 is a convex hull of its extreme points. Then, in order to prove that \(D\) is tight, it suffices to prove that each extreme point of \(D\) is achievable. Then, from convexification through time-sharing, all points in \(D\) are achievable.
In order to speak of the polytope, we re-write the constraints in (7) and (8) as

\[ Kd_i + (K - 1) \sum_{j=1,j \neq i}^{K} d_j \leq K - 1, \quad i = 1, \ldots, K \quad (46) \]

\[ -d_i \leq 0 \quad i = 1, \ldots, K \quad (47) \]

Then, we write all the left hand sides of (46) and (47) as an \( N \times K \) matrix \( H \) with corresponding right hand sides forming an \( N \)-length column vector \( h \), i.e., all points \( d \) in \( D \) satisfy

\[ Hd \leq h \quad (48) \]

where \( N = 2K \). By Theorem 7, exploring all extreme points of \( D \) is equivalent to finding all sub-matrices \( (H_J, h_J) \) of \( (H, h) \), such that

\[ \text{rank}(H_J) = K \quad (49) \]

and

\[ H_Jd = h_J, \quad \text{and} \quad Hd \leq h \quad (50) \]

where \( H_J \) is a sub-matrix of \( H \) with rows indexed by the index set \( J \), and \( h_J \) is the sub-vector of \( h \) with rows indexed by \( J \).

Let \( d \in D \) be a non-zero extreme point of \( D \). Define a subset \( S \subseteq \{1, \ldots, N\} \) as

\[ S \triangleq \left\{ s_i \triangleq s(i) : H_{s_i}d = h_{s_i} \text{ is } Kd_i + (K - 1) \sum_{j=1,j \neq i}^{K} d_j = K - 1, \quad i = 1, \ldots, K \right\} \quad (51) \]

where \( s(i) \) is a function of the coordinate \( i \) with the value as the row index of \( H \) corresponding to the active boundaries in (46). Similarly, define the set \( Z \subseteq \{1, \ldots, N\} \) as

\[ Z \triangleq \left\{ z_i \triangleq z(i) : H_{z_i}d = h_{z_i} \text{ is } d_i = 0, \quad i = 1, \ldots, K \right\} \quad (52) \]

where \( z(i) \) is a function of the coordinate \( i \) with the value as the row index of \( H \) corresponding to the active boundaries in (47). Clearly, \( S \) and \( Z \) are disjoint, i.e.,

\[ S \cap Z = \phi \quad (53) \]

For any row index set \( J \), which corresponds to a set of active boundaries for \( d \), we have

\[ J = S \cup Z \quad (54) \]

For example, for the three-user case, \( K = 3 \), according to (46) and (47), we have \( H \) and...
If the equalities with $i = 1, 2$ hold in (46) and the equality with $i = 3$ holds in (47), then the corresponding sets $S, Z, J$ are

$$S = \{s_1, s_2\} = \{1, 2\}, \quad Z = \{z_3\} = \{6\}, \quad J = S \cup Z = \{1, 2, 6\}$$

with the row-index functions

$$s_i = s(i) = i \quad (57)$$
$$z_i = z(i) = i + 3 \quad (58)$$

In this example, it is easy to check that

$$\operatorname{rank}(H_J) = \operatorname{rank} \begin{bmatrix} 3 & 2 & 2 \\ 2 & 3 & 2 \\ 2 & 2 & 3 \\ -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix} = 3 = K$$

and the solution given by $H_J \mathbf{d} = \mathbf{h}_J$ is

$$\mathbf{d} = \left( \frac{2}{5}, \frac{2}{5}, 0 \right)$$

which satisfies (50). Therefore, this is an extreme point.

For the general case, we have the following theorem.

**Theorem 8** A point $\mathbf{d} \in D$ of Theorem 2 is an extreme point if and only if it is equal to, up to element reordering,

$$\underbrace{\Delta, \ldots, \Delta}_{m \text{ items}}, \underbrace{0, \ldots, 0}_{(K-m) \text{ items}}, \quad 0 \leq m \leq K$$

where

$$\Delta = \frac{K - 1}{m(K - 1) + 1}$$

**Proof:** First, for any $m, 0 \leq m \leq K$, let the point $\mathbf{d}$ be as in (61). It is easy to check that
the sub-matrix \((H_J, h_J)\), where

\[
J = \left\{ s_i : 1 \leq i \leq m \right\} \cup \left\{ z_j : m + 1 \leq j \leq K \right\}
\]

(63)
satisfies all the conditions in Theorem 7, which means that \(d\) is an extreme point.

In order to show the other direction, we need to show that any extreme point \(d\) has the structure in (61) for some \(m, 0 \leq m \leq K\). To this end, we find the sub-matrix in Theorem 7.

If \(|Z| = K\), due to (47), the sub-matrix \(H_Z\) is simply a diagonal matrix with \(-1\)s on the diagonal, and consequently, \(\text{rank}(H_Z) = K\). Then, the solution of \(H_Zd = h_Z\) is 0, which satisfies (50). This extreme point corresponds to the case \(m = 0\) in Theorem 8.

In the rest of the proof, we focus on non-zero extreme points, i.e., \(|Z| < K\). Due to (46), it is easy to verify that \(H_S\) has \(|S|\) rows with \(\text{rank}(H_S) = |S|\) where \(S\) is defined in (51). In order to make \(\text{rank}(H_J) = \text{rank}(H_S \cup Z) = K\), we need at least \(K - |S|\) more rows from \(H\), i.e., \(|Z| \geq K - |S|\). If \(S\) is empty, then \(|Z| \geq K\), which contradicts the assumption \(|Z| < K\). Therefore, \(S\) is non-empty, i.e., \(|S| \geq 1\).

First, we claim that

\[
d_i = d_k, \quad \forall s_i, s_k \in S
\]

(64)

If \(|S| = 1\), there is nothing to prove, and we are done with the proof of (64). If \(|S| > 1\), consider any \(s_i, s_k \in S, i \neq k\). By the definition of \(S\), we have

\[
(K - 1)d_k + Kd_i + (K - 1) \sum_{l \neq i,k} d_l = K - 1
\]

(65)

\[
(K - 1)d_i + Kd_k + (K - 1) \sum_{l \neq i,k} d_l = K - 1
\]

(66)

which implies that \(d_i = d_k\) for any \(s_i, s_k \in S\), proving (64) for \(|S| \geq 1\).

Next, we claim

\[
d_i > 0, \quad \forall s_i \in S
\]

(67)

If \(|S| = K\), due to (64), (67) is trivially true since we are focusing on a non-zero extreme point. If \(|S| < K\), then we observe that

\[
d_i \geq d_j, \quad \forall s_i \in S, s_j \notin S
\]

(68)

which indicates that for any \(s_i \in S\) the corresponding element in vector \(d\) is the largest one, i.e., \(d_i = \max_k d_k\), which implies (67). Hence, it now suffices to show (68). We prove it by contradiction. Assume that there exists a coordinate \(j\) such that \(s_j \notin S\) and \(d_j\) is strictly
larger than $d_i$ for any $s_i \in S$. By the definition of $S$ in (51), we have

$$K - 1 = Kd_i + (K - 1)d_j + (K - 1) \sum_{l=1, l \neq i,j}^K d_l$$  \hspace{1cm} (69)$$

$$< Kd_i + (K - 1)d_j + (K - 1) \sum_{l=1, l \neq i,j}^K d_l + (d_j - d_i)$$  \hspace{1cm} (70)$$

$$= Kd_j + (K - 1)d_i + (K - 1) \sum_{l=1, l \neq i,j}^K d_l$$  \hspace{1cm} (71)$$

$$= Kd_j + (K - 1) \sum_{l=1, l \neq j}^K d_l$$  \hspace{1cm} (72)$$

which contradicts the constraint (46). Therefore, we must have (68) and consequently (67).

Finally, denote $m \triangleq |S|$, and, without loss of generality, assume that $S = \{s_i : 1 \leq i \leq m\}$. By (67) and the definition of $Z$ in (52), we note that $z_j \in Z$ only if $s_j \notin S$. Together with the constraint $|Z| \geq K - |S| = K - m$, we conclude that we must have $Z = \{z_j : m+1 \leq j \leq K\}$, i.e., $d_j = 0$ for $m+1 \leq j \leq K$. Thus, $\text{rank}(H_{S \cup Z}) = K$, and, by (64), the solution given by the corresponding equations can be characterized as (61), which satisfies (50), completing the proof. ■

4.3 Achievability

The previous section showed that the converse region is a polytope with extreme points which have $m$ coordinates all equal to $\Delta$ given in (62), and the remaining $K - m$ coordinates all equal to zero. It is clear that zero vector is an extreme point in $D$ and is trivially achievable. The rest of the achievability proof focuses on non-zero extreme points. In this section, we prove that each of these extreme points is achievable. Without loss of generality, we prove that the s.d.o.f. point of

$$d = \left( \underbrace{\Delta, \ldots, \Delta}_{m \text{ items}}, 0, \ldots, 0 \right)$$

is achievable for all $1 < m < K$ with $\Delta$ in (62). By symmetry, this proves the achievability of all extreme points. Note that $m = K$ is shown in [11, 2], and $m = 1$ is shown in [40].

**Theorem 9** The extreme point $d \in D$ given in (73) is achieved by $m$-user Gaussian MAC wiretap channel with $K - m$ helpers for almost all channel gains.

**Proof:** Consider the $m$-user Gaussian MAC wiretap channel with $K - m$ helpers where transmitter $i$, $i = 1, \ldots, m$, has confidential message $W_i$ intended for the legitimate receiver and the remaining $K - m$ transmitters serve as independent helpers without messages of their own.
In order to achieve the extreme point \( \mathbf{d} \) in (73), transmitter \( i, \; i = 1, \ldots, m \), divides its message into \( K - 1 \) mutually independent sub-messages. Each transmitter sends a linear combination of signals that carry the sub-messages. In addition to message carrying signals, all transmitters also send cooperative jamming signals \( U_i, \; i = 1, \ldots, K \), respectively. The messages are sent in such a way that all of the cooperative jamming signals are aligned in a single dimension at the legitimate receiver, occupying the smallest possible space at the legitimate receiver, and hence allowing for the reliable decodability of the message carrying signals. In addition, each cooperative jamming signal is aligned with at most \( K - 1 \) message carrying signals at the eavesdropper to limit the information leakage rate to the eavesdropper. An example of \( K = 3, \; m = 2, \) and \( K - m = 1 \) is given in Figure 6.

More specifically, we use a total of \( m(K - 1) + K \) mutually independent random variables

\[
V_{ij}, \quad i \in \{1, \ldots, m\}, \; j \in \{1,\cdots,K\} \setminus \{i\} \quad (74)
\]

\[
U_k, \quad k \in \{1,\cdots,K\} \quad (75)
\]

where \( \{V_{ij}\}_{j \neq i} \) denote the message carrying signals and \( U_i \) denotes the cooperative jamming signal sent from transmitter \( i \). In particular, \( V_{ij} \) carries the \( j \)th sub-message of transmitter \( i \). Each of these random variables is uniformly and independently drawn from the same discrete constellation \( C(a, Q) \) given in (21), where \( a \) and \( Q \) will be specified later. We choose the input signals of the transmitters as

\[
X_i = \sum_{j=1, j \neq i}^{K} \frac{g_j}{h_j g_i} V_{ij} + \frac{1}{h_i} U_i, \quad i \in \{1, \ldots, m\} \quad (76)
\]

\[
X_j = \frac{1}{h_j} U_j, \quad j \in \{m + 1, \ldots, K\} \quad (77)
\]

With these input selections, observations of the receivers are

\[
Y_1 = \left[ \sum_{i=1}^{m} \sum_{j=1, j \neq i}^{K} \frac{g_j h_i}{h_j g_i} V_{ij} \right] + \left( \sum_{k=1}^{K} U_k \right) + N_1 \quad (78)
\]

and

\[
Y_2 = \sum_{j=1}^{K} \frac{g_j}{h_j} \left( U_j + \sum_{i=1, i \neq j}^{m} V_{ij} \right) + N_2 \quad (79)
\]

where the terms inside the parentheses (\( \cdot \)) in (78) and (79) are aligned.

By [36, Theorem 1], we can achieve the following sum secrecy rate for the \( m \) users

\[
\sup_{\mathbf{d}} \sum_{i=1}^{m} R_i \geq I(\mathbf{V}; Y_1) - I(\mathbf{V}; Y_2) \quad (80)
\]
Figure 6: Illustration of secure interference alignment for the s.d.o.f. triple \((\frac{2}{3}, \frac{2}{3}, 0)\) for the two-user MAC wiretap channel with one helper; \(K = 3\) and \(m = 2\). Here, we define \(V_i = \{V_{ij} : j = 1, 2, 3, j \neq i\}\) for \(i = 1, 2, 3\).

where \(V_i \triangleq \{V_{ij} : i \in \{1, \ldots, m\}, \ j \in \{1, \cdots, K\} \setminus \{i\}\}\).

By Lemma 1 for any \(\delta > 0\), if we choose \(Q = P^{2(m(K-1)+1+\delta)}\) and \(a = \gamma P^{\frac{1}{2}}/Q\), where \(\gamma\) is a constant independent of \(P\) to meet the average power constraint, then

\[
\Pr[V \neq \hat{V}] \leq \exp(-\beta P^\delta)
\]  

for some constant \(\beta > 0\) (independent of \(P\)), where \(\hat{V}\) is the estimate of \(V\) by choosing the closest point in the constellation based on observation \(Y_1\). This means that we can have \(\Pr[V \neq \hat{V}] \to 0\) as \(P \to \infty\).

By Fano’s inequality and the Markov chain \(V \rightarrow Y_1 \rightarrow \hat{V}\), we know that

\[
H(V|Y_1) \leq H(V|\hat{V}) \leq 1 + \exp(-\beta P^\delta) \log(2Q + 1)^{m(K-1)}
\]

\[
= o(\log P)
\]

where \(o(\cdot)\) is the little-o function. This means that

\[
I(V; Y_1) = H(V) - H(V|Y_1)
\]

\[
= \log(2Q + 1)^{m(K-1)} - H(V|Y_1)
\]

\[
\geq \log(2Q + 1)^{m(K-1)} - o(\log P)
\]
On the other hand, we can bound the second term in (80) as

\[ I(V;Y_2) - I(V;Y_2 - N_2) \leq I(V;Y_2 - N_2) \]

(88)

\[ = \sum_{j=1}^{K} H\left(U_j + \sum_{i=1,i\neq j}^{m} V_{ij}\right) - H(U_1, \ldots, U_K) \]

(89)

\[ \leq K \log \frac{2KQ + 1}{2Q + 1} \]

(90)

\[ \leq K \log K \]

(91)

\[ = o(\log P) \]

(92)

where (90) is due to the fact that entropy of each \( U_j + \sum_{i=1,i\neq j}^{m} V_{ij} \) is maximized by the uniform distribution which takes values over a set of cardinality \( 2KQ + 1 \).

Combining (87) and (92), we obtain

\[ \sup_{m \sum_{i=1}^{m} R_i} \geq I(V;Y_1) - I(V;Y_2) \]

(93)

\[ \geq \log(2Q + 1)^{m(K-1)} - o(\log P) \]

(94)

\[ = \frac{m(K-1)(1-\delta)}{m(K-1) + 1 + \delta} \left( \frac{1}{2} \log P \right) + o(\log P) \]

(95)

By choosing \( \delta \) arbitrarily small, we can achieve the sum s.d.o.f. of \( \frac{m(K-1)}{m(K-1)+1} \) for almost all channel gains, which implies that the s.d.o.f. tuple of

\[ \left( \frac{(K-1)}{m(K-1) + 1}, \ldots, \frac{(K-1)}{m(K-1) + 1}, 0, \ldots, 0 \right) \]

(96)

is achievable by symmetry, which is (73). ■

5 S.d.o.f. Region of K-User IC with Secrecy Constraints

In this section, we study the K-user IC with secrecy constraints defined in Section 2.2 and prove the s.d.o.f. region stated in Theorem 4. To this end, we consider both IC-CM and IC-EE and their combination IC-CM-EE in a unified framework. We first illustrate the regions for \( K = 2, 3, 4 \) cases as examples. The purpose of presenting \( K = 4 \) as an example is to show that, unlike the MAC case, starting with \( K = 4 \) interference constraints become effective and binding. We then provide converses separately for IC-EE and IC-CM in Section 5.1 and Section 5.2 respectively, which imply a converse for IC-CM-EE. Finally, we
show the achievability for IC-CM-EE, which implies the achievability for IC-EE and IC-CM. Specifically, we investigate the converse region in terms of its extreme points in Section 5.3 and show the general achievability in Section 5.4.

For $K = 2$, the s.d.o.f. region in Theorem 4 becomes

$$D = \left\{ \mathbf{d} : \begin{array}{l}
2d_1 + d_2 \leq 1, \\
d_1 + 2d_2 \leq 1, \\
d_1, d_2 \geq 0
\end{array} \right\}$$

(97)

which is the same as (36), and is shown in Figure 1. Note that (15) is not necessary for the two-user case, since summing the bounds $2d_1 + d_2 \leq 1$ and $d_1 + 2d_2 \leq 1$ up gives a new bound

$$d_1 + d_2 \leq \frac{2}{3}$$

(98)

which is the result in Theorem 3 and makes the constraint in (15) strictly loose.

In order to provide the achievability, it suffices to check that the extreme points $(0, 0), (\frac{1}{2}, 0), (0, \frac{1}{2}), \text{and } (\frac{1}{3}, \frac{1}{3})$ are achievable. In fact the achievabilities of $(\frac{1}{2}, 0), (0, \frac{1}{2})$ are similar to [40] and will be shown in Section 5.3. The achievability of $(\frac{1}{3}, \frac{1}{3})$ was proved in [3,4]. Note that $(\frac{1}{3}, \frac{1}{3})$ is the only sum s.d.o.f. optimum point.

For $K = 3$, the s.d.o.f. region in Theorem 4 becomes

$$D = \left\{ \mathbf{d} : \begin{array}{l}
3d_1 + d_2 + d_3 \leq 2, \\
d_1 + 3d_2 + d_3 \leq 2, \\
d_1 + d_2 + 3d_3 \leq 2, \\
d_1, d_2, d_3 \geq 0
\end{array} \right\}$$

(99)

and (15) is not necessary for the three-user case, either. This is because, due to the positiveness of each element in $\mathbf{d}$, from the first two inequalities in (99), we have

$$3d_1 + d_2 \leq 3d_1 + d_2 + d_3 \leq 2$$

(100)

$$d_1 + 3d_2 \leq d_1 + 3d_2 + d_3 \leq 2$$

(101)

Summing the left hand sides up of (100) and (101) gives us

$$d_1 + d_2 \leq 1$$

(102)

which is (15) with $V = \{1, 2\}$, and we have (15) for free from (99).
The extreme points of this region are:

\[
(0, 0, 0), \left(\frac{2}{3}, 0, 0\right), \left(0, \frac{2}{3}, 0\right), \left(0, 0, \frac{2}{3}\right), \\
\left(\frac{1}{2}, \frac{1}{2}, 0\right), \left(\frac{1}{2}, 0, \frac{1}{2}\right), \left(0, \frac{1}{2}, \frac{1}{2}\right), \\
\left(\frac{2}{5}, \frac{2}{5}, \frac{2}{5}\right)
\] (103)

which correspond to the maximum individual s.d.o.f. (see Gaussian wiretap channel with two helpers [40] and Section 5.3), the maximum sum of pair of s.d.o.f. (proved in Section 5.3), and the maximum sum s.d.o.f. (see three-user Gaussian IC-CM-EE in [3, 4]). Note that, \((\frac{1}{2}, \frac{1}{2})\) is the maximum sum d.o.f. for a two-user IC without secrecy constraints, and \((\frac{2}{5}, \frac{2}{5}, \frac{2}{5})\) is the only sum s.d.o.f. optimum point. Finally, note the difference of the extreme points of the 3-user IC in (103) from the corresponding 3-user MAC in (38), even though the s.d.o.f. regions and the extreme points of the 2-user IC and 2-user MAC in (97) and (56) were the same.

For \(K = 4\), the s.d.o.f. region in Theorem 4 becomes

\[
D = \left\{ \mathbf{d} : 4d_1 + d_2 + d_3 + d_4 \leq 3, \\
4d_2 + d_3 + d_4 \leq 3, \\
d_1 + d_2 + 4d_3 + d_4 \leq 3, \\
d_1 + d_2 + d_3 + 4d_4 \leq 3, \\
d_1 + d_2 \leq 1, \\
d_1 + d_3 \leq 1, \\
d_1 + d_4 \leq 1, \\
d_2 + d_3 \leq 1, \\
d_2 + d_4 \leq 1, \\
d_3 + d_4 \leq 1, \\
d_1, d_2, d_3, d_4 \geq 0 \right\}
\] (104)
The extreme points of this region are:

\[(0,0,0), \left(\frac{3}{4},0,0,0\right), \left(0,\frac{3}{4},0,0\right), \left(0,0,\frac{3}{4},0\right), \left(0,0,0,\frac{3}{4}\right), \left(\frac{2}{3},\frac{1}{3},0,0\right)\]

up to element reordering

\[\left(\frac{1}{2},\frac{1}{2},\frac{1}{2},0\right), \left(\frac{1}{2},0,\frac{1}{2},\frac{1}{2}\right), \left(0,\frac{1}{2},\frac{1}{2},\frac{1}{2}\right)\]

\[\left(3,3,3,3,3\right), \left(\frac{1}{7},\frac{1}{7},\frac{1}{7},\frac{1}{7}\right)\]

Here, in contrast to the two-user and three-user cases, (15) is absolutely necessary. For example, the point \((\frac{3}{5},\frac{3}{5},0,0)\) satisfies (14), but not (15). In fact, it cannot be achieved, and (15) is strictly needed to enforce that fact.

Regarding the region in Theorem 4 as illustrated in the examples above, we provide a few general comments here:

1) Although (15) only states the constraints for all pairs of rates, due to the same argument in [51], it can equivalently be stated as \(\sum_{i \in V} d_i \leq \frac{|V|}{2}\) for all \(|V| \geq 2\). We note that, when \(|V| = K\), the corresponding upper bound is strictly loose due to Theorem 1 in [3,4], and that is why such bounds were not needed in [3,4], where sum s.d.o.f. was characterized.

2) As shown in the examples, when \(K = 2\) or 3, (15) is not necessary. When \(K \geq 4\), we need both (14) and (15) to completely characterize the region \(D\). Neither of them can be removed from the theorem. For example, the all \(\frac{1}{2}\) vector, \((\frac{1}{2},\frac{1}{2},\ldots,\frac{1}{2})\), satisfies (15), but not (14). On the other hand, the point \((\frac{K-1}{K+1},\frac{K-1}{K+1},0,0,\ldots,0)\), which has only two non-zero elements, satisfies (14), but not (15) for any \(K \geq 4\). Therefore, (15) emerges only when \(K \geq 4\). To the best of our knowledge, this is the first time that \(K = 2\) or \(K = 3\) do not represent the most generality of a multi-user problem, and we need to go up to \(K = 4\) for this phenomenon to appear.

3) Different portions of the region \(D\) are governed by different upper bounds. To see this, we can study the structure of the extreme points of \(D\), since \(D\) is the convex hull of them. The sum s.d.o.f. tuple, which is symmetric and has no zero elements, is governed by the upper bounds in (14) due to secrecy constraints. However, as will be shown in Theorem 10 in Section 5.3, all other extreme points have zeros as some elements, and therefore are governed by the upper bounds in (15) due to interference constraints in [50,51]. An explanation can be provided as follows: When some transmitters do not have messages to transmit, we may employ them as “helpers”. Even though secrecy constraint is considered in our problem, with the help of the “helpers”, the effect due
to the existence of the eavesdropper in the network can be eliminated. Hence, this portion of the s.d.o.f. region is dominated by the interference constraints.

5.1 Converse for $K$-User IC-EE

The constraint in (15) follows from the non-secrecy constraints on the $K$-user IC in [50, 51]. We note that this same constraint is valid for the converse proof of IC-CM in the next section as well.

In order to prove (14) in Theorem 4, we re-examine [3, Eqn. (23)]. Originally, we applied [40, Lemma 2] in [3] by treating the signal from transmitter $j$ as the unintended noise to its neighboring transmitter-receiver pair $j-1$, i.e., for any $i = 1, \ldots, K$,

$$n \sum_{j=1}^{K} R_j \leq \sum_{j=1, j \neq i}^{K} h(\tilde{X}_j) + nc_1$$

(106)

$$\leq [h(Y_K) - nR_K] + [h(Y_1) - nR_1] + \cdots + [h(Y_{i-2}) - nR_{i-2}]
+ [h(Y_i) - nR_i] + \cdots + [h(Y_{K-1}) - nR_{K-1}] + nc_2$$

(107)

By noting that $h(Y_j) \leq \frac{n}{2} \log P + nc_j'$ for each $j$, we have

$$2n \sum_{j=1}^{K} R_j \leq (K-1) \frac{n}{2} \log P + nR_i + nc_3$$

(108)

Therefore, we have a total of $K$ bounds for $i = 1, \ldots, K$. Summing these $K$ bounds, we obtained:

$$(2K-1)n \sum_{j=1}^{K} R_j \leq K(K-1) \frac{n}{2} \log P + nc_4$$

(109)

which gave

$$D_{s,\Sigma} \leq \frac{K(K-1)}{2K-1}$$

(110)

completing the converse proof for the sum s.d.o.f. of IC-EE in [3] (also Theorem 3 in this paper).
Here, we continue from [3, Eqn. (23)] and re-interpret it as:

\[
\begin{align*}
    n \sum_{j=1}^{K} R_j &\leq \sum_{j=1, j \neq i}^{K} h(\tilde{X}_j) + nc_5 \\
    &\leq \left[ h(Y_i) - nR_i \right] + \cdots + \left[ h(Y_i) - nR_i \right] + nc_6 \\
    &\leq (K-1)h(Y_i) - (K-1)nR_i + nc_6
\end{align*}
\]

where \( i \in \{1, \ldots, K\} \) is arbitrary. Here, the second inequality means that we apply [40, Lemma 2] by treating the signal from all transmitters \( j \neq i \) as the unintended noise to the transmitter-receiver pair \( i \).

Rearranging the terms in (114), dividing both sides by \( n \frac{2}{2} \log P \), and taking the limit \( P \to \infty \) on both sides, we obtain

\[
Kd_i + \sum_{j=1, j \neq i}^{K} d_j \leq K - 1, \quad i = 1, \ldots, K
\]

which is (14) in Theorem 4, completing the converse proof for IC-EE.

5.2 Converse for \( K \)-User IC-CM

When we studied the sum s.d.o.f. of IC-CM, we applied [40, Lemma 2] to [3, Eqn. (44)] by treating the signal from transmitter \( j \) as the unintended noise to its neighbor transmitter-receiver pair \( j + 1 \), i.e., for any \( i = 1, \ldots, K \)

\[
\begin{align*}
    n \sum_{j=1, j \neq i}^{K} R_j &\leq \sum_{j=1}^{K} h(\tilde{Y}_j) - h(Y_i) + nc_8 \\
    &\leq \left[ \sum_{j=1}^{K-1} \left[ h(Y_{j+1}) - nR_{j+1} \right] \right] + \left[ h(Y_1) - nR_1 \right] - h(Y_i) + nc_9 \\
    &\leq \sum_{j=1}^{K} \left[ h(Y_j) - nR_j \right] - h(Y_i) + nc_9
\end{align*}
\]

By noting that \( h(Y_j) \leq \frac{n}{2} \log P + nc_j \) for each \( j \), we have

\[
\begin{align*}
    nR_i + 2n \sum_{j=1, j \neq i}^{K} R_j &\leq \sum_{j=1, j \neq i}^{K} h(Y_j) + nc_9 \\
    &\leq (K-1)\frac{n}{2} \log P + nc_{10}
\end{align*}
\]
Therefore, we have a total of $K$ bounds for $i = 1, \ldots, K$. Summing these $K$ bounds, we obtained

$$(2K - 1)n \sum_{j=1}^{K} R_j \leq K(K - 1) \frac{n}{2} \log P + n c_{11}$$

which gave

$$D_s, \Sigma \leq \frac{K(K - 1)}{2K - 1}$$

completing the converse proof for the sum s.d.o.f. of IC-CM in [3] (also Theorem 3 in this paper).

Here, we continue from [3, Eqn. (44)] and re-interpret it as follows: For any $i \in \{1, \ldots, K\}$, we select

$$k \triangleq \begin{cases} 
  i - 1, & \text{if } i \geq 2 \\
  K, & \text{if } i = 1
\end{cases}$$

and then have

$$n \sum_{j=1, j \neq i}^{K} R_j \leq \left[ \sum_{j=1}^{K} h(\tilde{X}_j) \right] - h(Y_i) + n c_{12}$$

$$\leq h(\tilde{X}_k) + \left[ \sum_{j=1, j \neq k}^{K} h(\tilde{X}_j) \right] - h(Y_i) + n c_{13}$$

$$\leq h(Y_i) - n R_i + \left[ \sum_{j=1, j \neq k}^{K} h(\tilde{X}_j) \right] - h(Y_i) + n c_{14}$$

$$= \left[ \sum_{j=1, j \neq k}^{K} h(\tilde{X}_j) \right] - n R_i + n c_{14}$$

$$\leq \underbrace{[h(Y_k) - n R_k] + \cdots + [h(Y_k) - n R_k]}_{K-1 \text{ items}} - n R_i + n c_{15}$$

$$= (K - 1)h(Y_k) - (K - 1)n R_k - n R_i + n c_{15}$$

$$\leq (K - 1) \left( \frac{n}{2} \log P \right) - (K - 1)n R_k - n R_i + n c_{15}$$

which is

$$(K - 1)n R_k + n \sum_{j=1}^{K} R_j \leq (K - 1) \left( \frac{n}{2} \log P \right) + n c_{15}$$

Here, inequality (126) means that we apply [40, Lemma 2] by treating the signal from
transmitter \( k \) as the unintended noise to the transmitter-receiver pair \( i \). Similarly, inequality (128) means that we apply [40, Lemma 2] by treating the signal from transmitter \( j \neq k \) as the unintended noise to the transmitter-receiver pair \( k \).

Rearranging the terms in (131), dividing both sides by \( \frac{n}{2} \log P \), and taking the limit \( P \to \infty \) on both sides, we obtain

\[
Kd_k + \sum_{j=1, j \neq k}^{K} d_j \leq K - 1, \quad k = 1, \ldots, K
\]

which is (131) in Theorem 4, completing the converse proof for IC-CM.

### 5.3 Polytope Structure and Extreme Points

Similar to the discussion and approach in the MAC problem in Section 4.2, it is easy to see that the region \( D \) characterized by Theorem 4 is a polytope, which is equal to the convex combinations of all extreme points of \( D \) due to Theorem 6. Therefore, in order to show the tightness of region \( D \), it suffices to prove that all extreme points of \( D \) are achievable.

We first assume that \( K \geq 3 \), and determine the structure of all extreme points of \( D \) in the following theorem.

**Theorem 10** For the \( K \)-dimensional region \( D, K \geq 3 \), in Theorem 4, any extreme point must be a point with one of the following structures:

\[
(0, 0, \ldots, 0),
\]

\[
\left(\frac{K-1-p}{K-p}, \frac{1}{K-p}, \ldots, \frac{1}{K-p}, 0, \ldots, 0\right), \quad K - 2 \geq p \geq 0, \quad m = K - 1 - p \geq 1
\]

\[
\left(\frac{1}{p} \text{ items}, \frac{1}{K-1} \text{ items}, 0, \ldots, 0\right), \quad K - 2 \geq p' \geq 3, \quad m' \geq 1, \quad p' + m' = K \geq 5
\]

\[
\left(\frac{K-1}{2K-1}, \frac{K-1}{2K-1}, \ldots, \frac{K-1}{2K-1}\right)
\]

up to element reordering.

The proof of Theorem 10 is provided in Appendix A.

Now, in order to show the tightness of region \( D \), it suffices to show the achievability for each structure in Theorem 10. Clearly, the zero vector in (133) is trivially achievable. The symmetric tuple in (136) is achievable due to [34]. Therefore, it remains to show the achievability of the structures in (134) and (135).
In order to address the achievabilities of (134) and (135), we formulate a new channel model as a \((p + 1)\)-user IC-CM-EE channel with \(m\) independent helpers and \(N\) independent external eavesdroppers. The formal definition of this channel model is given in Section 5.4. Then, we have the following theorem.

**Theorem 11** For the \((p + 1)\)-user IC-CM-EE channel with \(m\) independent helpers and \(N\) independent external eavesdroppers, as far as \(p \geq 0, m \geq 1,\) and \(N\) is finite, the following s.d.o.f. tuple is achievable:

\[
\left( \frac{m}{m+1}, \frac{1}{m+1}, \frac{1}{m+1}, \ldots, \frac{1}{m+1} \right)
\]

for almost all channel gains.

The proof of Theorem 11 is provided in Section 5.4.

Here, we provide a few comments about Theorem 11. Theorem 11 provides quite general results, and subsumes some other known cases:

1) The result in [40] is a special case of Theorem 11 with \(p = 0, m \geq 1, N = 1.\)

2) (134) is a special case of Theorem 11 with \(p \geq 0, m = K - 1 - p \geq 1, N = m + 1.\)

3) (135) is a byproduct of Theorem 11. By choosing \(p = p' - 1, m = 1, N = m' + 1,\) we know that with just one helper, the following s.d.o.f. tuple is achievable:

\[
\left( \frac{1}{2}, \frac{1}{2}, \ldots, \frac{1}{2}, 0 \right)
\]

Now, if we add \(m' - 1\) more independent helpers into the network, (135) can be achieved trivially.

Therefore, with the help of Theorem 11, each structure in Theorem 10 can be achieved, which provides the achievability proof for Theorem 4 for \(K \geq 3.\)

Finally, we address the \(K = 2\) case. In this case, the region \(D\) characterized by (14)-(16) in Theorem 4 is given by (97). In order to provide the achievability, it suffices to prove that the extreme points \((\frac{1}{2}, 0), (0, \frac{1}{2}),\) and \((\frac{1}{3}, \frac{1}{3})\) are achievable. The achievability of \((\frac{1}{3}, \frac{1}{3})\) was proved in [34]. The achievabilities of \((\frac{1}{2}, 0), (0, \frac{1}{2})\) are the special cases of Theorem 11 with \(p = 0, m = 1, N = 2.\)
5.4 Achievability

The \((p+1)\)-user IC-CM-EE channel with \(m\) independent helpers and \(N\) independent external eavesdroppers is

\[
Y_i = \sum_{j=1}^{p+1+m} h_{ji} X_j + N_i, \quad i = 1, \ldots, p + 1
\]

(139)

\[
Z_k = \sum_{j=1}^{p+1+m} g_{jk} X_j + N_{zk}, \quad k = 1, \ldots, N
\]

(140)

where \(Y_i\) is the channel output of receiver \(i\), \(Z_k\) is the channel output of external eavesdropper \(k\), \(X_j\) is the channel input of transmitter \(j\), \(h_{ji}\) is the channel gain of the \(j\)th transmitter to the \(i\)th receiver, \(g_{jk}\) is the channel gain of the \(j\)th transmitter to the \(k\)th eavesdropper, and \(\{N_1, \ldots, N_{p+1}, N_z_1, \ldots, N_z_N\}\) are mutually independent zero-mean unit-variance Gaussian random variables. All the channel gains are independently drawn from continuous distributions, and are time-invariant throughout the communication session. We further assume that all \(h_{ji}\) and \(g_{jk}\) are non-zero. All channel inputs satisfy average power constraints, \(\mathbb{E}[X_j^2] \leq P\), for \(j = 1, \ldots, p + 1 + m\).

Transmitter \(j, j = p + 2, \ldots, p + 1 + m\), is an independent helper in the network. On the other hand, each transmitter \(i, i = 1, \ldots, p + 1\), has a message \(W_i\) intended for the receiver \(Y_i\). A rate tuple \((R_1, \ldots, R_{p+1})\) is said to be achievable if for any \(\epsilon > 0\), there exist joint \(n\)-length codes such that each receiver \(i\) can decode the corresponding message reliably, i.e., the probability of decoding error is less than \(\epsilon\) for all messages,

\[
\max_i \Pr[W_i \neq \hat{W}_i] \leq \epsilon
\]

(141)

where \(\hat{W}_i\) is the estimation based on its observation \(Y_i\). The secrecy constraints are defined as follows:

\[
\frac{1}{n} H(W_{p+1}^i | Y_i) \geq \frac{1}{n} H(W_{p+1}^i) - \epsilon, \quad i = 1, \ldots, p + 1
\]

(142)

\[
\frac{1}{n} H(W_1, \ldots, W_{p+1} | Z_k) \geq \frac{1}{n} H(W_1, \ldots, W_{p+1}) - \epsilon, \quad k = 1, \ldots, N
\]

(143)

where \(W_{p+1}^i \triangleq \{W_1, \ldots, W_{p+1}\} \setminus \{W_i\}\). A s.d.o.f. tuple, \((d_1, \ldots, d_{p+1})\), is achievable if there exists an achievable rate tuple \((R_1, \ldots, R_{p+1})\) such that

\[
d_i = \lim_{P \to \infty} \frac{R_i}{\frac{1}{2} \log P}
\]

(144)

for \(i = 1, \ldots, p + 1\).

Now, we prove Theorem 11, i.e., for \(p \geq 0, m \geq 1\), and \(N\) is finite, the following
The s.d.o.f. tuple is achievable:

\[
\left( \frac{m}{m+1}, \frac{1}{m+1}, \frac{1}{m+1}, \ldots, \frac{1}{m+1} \right)
\]

for almost all channel gains.

The purpose of Theorem 11 is to prove the achievability of the structure (134) in Theorem 10. As shown in (134), we partition the transmitters into three groups: 1) the first group consists of only one transmitter with the largest s.d.o.f., \( \frac{K-1-p}{K-p} \), which is no smaller than \( \frac{1}{2} \), 2) the second group consists of \( p \geq 0 \) transmitters with the same s.d.o.f., \( \frac{1}{K-p} \), which is no larger than \( \frac{1}{2} \), and 3) the third group consists of \( m \geq 1 \) transmitters serving as independent helpers. Therefore, in (145), we consider the \((p+1)\)-user IC with \( m \) helpers where \( K = p + 1 + m \). Therefore, (145) and Theorem 11 show the achievability of (134). We know from remark 2) above that the achievability of (135) is a byproduct of Theorem 11. Also, (133) is trivially achieved, and the achievability of (136) is shown in [3, 4]. Therefore, we focus on Theorem 11 from this point on.

The technique we use in the proof of Theorem 11 is asymptotical interference alignment [46] and structured cooperative jamming [18]. The alignment scheme is illustrated in Figure 7 with \( m = 3, p = 2, N = 1 \). In Figure 7, we partition the transmitters into three groups, which are \( \{X_1\} \) as the first group, \( p = 2 \) other transmitters \( \{X_2, X_3\} \) as the second group, and \( m = 3 \) helpers as the third group. From the perspective of \( Y_1 \) and the eavesdropper \( Z \), due to the existence of independent helpers, the alignment signaling design is similar to that in wiretap channel with helpers in [40, Fig. 4]. However, from the perspective of \( Y_2, Y_3 \), and the eavesdropper \( Z \), the alignment signaling design is similar to that in the interference channel in [3, Fig. 2] (see the details of the corresponding design in [4]). This suggests that the signalling scheme that achieves on arbitrary extreme point of the s.d.o.f. region is in between the signalling scheme that achieves the sum s.d.o.f. of IC-CM-EE in [3, 4] and the signalling scheme used in the helper network in [40]. Furthermore, if we let \( p = 0 \), the signalling scheme in Figure 7 would be almost identical to [40, Fig. 4]. However, we cannot let \( m \) be equal to 0. As far as the number of independent helper(s) in Figure 7, \( m \), is non-zero, in contrast to the scheme in [3, Fig. 2], the legitimate transmitters in the first and second groups do not send cooperative jamming signals by themselves, however, in [3, 4] for IC-CM-EE without helpers, each legitimate transmitter needed to send both message signals and a cooperative signal. Note that in Figure 7 here, legitimate transmitters \( \{X_1, X_2, X_3\} \) do not send any cooperative jamming signals (no shaded boxes).

Here, we give the general achievable scheme. Let \( l \) be a large constant. Let us define a
Figure 7: Illustration of secure interference alignment of Theorem 11 with $m = 3, p = 2, N = 1$.

set $T_1$ which will represent dimensions as follows:

$$T_1 \triangleq \left\{ \left( \prod_{(j,k) \in L} h_{jk}^{r_{jk}} \right) \left( \prod_{k=1}^{N-p+1} \prod_{j=1}^m g_{jk}^{s_{jk}} \right) : r_{jk}, s_{jk} \in \{1, \ldots, l\} \right\}$$  \hspace{1cm} (146)

where $L$ contains almost all pairs corresponding to the cross-link channel gains

$$L = \left\{ (j,k) : j \in \{2, \ldots, p+2\}, k = 1 \right\}$$

$$\cup \left\{ (j,k) : j \in \{1, \ldots, p+1+m\}, k \in \{2, \ldots, p+1\}, j \neq k \right\}$$  \hspace{1cm} (147)

Clearly, starting from the second helper $X_{p+3}$, if there exists any, the cross-link channel gains to the first legitimate receiver $Y_1$ are not in the set $L$. Therefore, we define the sets $\{T_j\}_{j=2}^m$

$$T_j = \frac{1}{h_{p+1+j,1}}T_1, \quad j = 2, \ldots, m$$  \hspace{1cm} (148)

Let $M_i$ be the cardinality of $T_i, i = 1, \ldots, m$. Note that all $M_i$ are the same, thus we denote
them as \( M \),
\[
M \triangleq l^{L+|N(p+1+m)|} = l^\theta
\] (149)
where \( \theta \triangleq (p+1+m)p + p + N(p+1+m) + 1 \).

Let \( t_{ij} \) and \( t_{(j)} \) be the vector containing all the elements in the set \( T_j \) for any possible \( i \). Therefore, \( t_{ij} \) and \( t_{(j)} \) are \( M \)-dimensional vectors containing \( M \) rationally independent real numbers in \( T_j \). The sets \( t_{ij} \) and \( t_{(j)} \) will represent the dimensions along which message signals are transmitted. In particular, as illustrated in Figure 7, for each legitimate transmitter \( i \), \( i = 1, \ldots, p + 1 \), the message signal \( V_{i1} \) is transmitted in dimensions \( t_{i1}. \) In order to asymptotically align \( U_1 \) from the first helper \( X_{p+2} \) with all \( V_{i1} \)s, the cooperative jamming signal \( U_1 \) is transmitted in dimensions \( t_{(1)} \). Similarly, for the first transmitter \( X_1 \), the message signal \( V_{1j}, j = 2, \ldots, m \), is transmitted in dimensions \( t_{1j}. \) Since we want to align the cooperative jamming signal \( U_j \) from the helper \( X_{p+1+j} \) with \( V_{ij} \) one by one, the jamming signal \( U_j \) is transmitted in dimensions \( t_{(j)} \).

Let us define an \( mM \) dimensional vector \( b_1 \) by stacking \( t_{i1} \)s as
\[
b_1^T = [t_{11}^T, t_{12}^T, \ldots, t_{1m}^T] \] (150)
Then, transmitter 1 generates a vector \( a_1 \), which contains a total of \( mM \) discrete signals each identically and independently drawn from \( C(a, Q) \) given in (21). For convenience, we partition this transmitted signal as
\[
a_1^T = [v_{11}^T, v_{12}^T, \ldots, v_{1m}^T] \] (151)
where \( v_{1j} \) represents the information symbols in \( V_{1j}. \) Each of these vectors has length \( M \), and therefore, the total length of \( a_1 \) is \( mM \). The channel input of transmitter 1 is
\[
x_1 = a_1^T b_1 \] (152)

Similarly, for the second group transmitters \( X_i, i = 2, \ldots, p + 1 \), let \( b_i \) be \( b_i = t_{i1}. \) Then, transmitter \( i \) generates a vector \( a_i = v_{i1}, \) which contains a total of \( M \) discrete signals each identically and independently drawn from \( C(a, Q) \) given in (21). The channel input of transmitter \( i \) is
\[
x_i = a_i^T b_i = v_{i1}^T t_{i1}, \quad i = 2, \ldots, p + 1 \] (153)

Finally, for the third group transmitters \( X_k, k = p + 2, \ldots, p + 1 + m \), serving as the helpers, let \( b_k \) be \( b_k = t_{(k-1)} \). Then, helper \( k \) generates a vector \( u_{k-1} \) representing the cooperative jamming signal in \( U_{k-1}, \) which contains a total of \( M \) discrete signals each identically and independently drawn from \( C(a, Q) \) given in (21). The channel input of transmitter \( k \) is
\[
x_k = u_{k-1}^T b_k = u_{k-1}^T t_{(k-1)}, \quad k = p + 2, \ldots, p + 1 + m \] (154)
Before we investigate the performance of this signalling scheme, we analyze the structure of the received signals at the receivers. To see the detailed dimension structure of the received signals at the receivers, let us define \( \tilde{T}_i \) as a superset of \( T_i \), as follows

\[
\tilde{T}_1 \triangleq \left\{ \left( \prod_{(j,k) \in L} h_{j,k}^{r_{jk}} \right) \left( \prod_{k=1}^{N} \prod_{j=1}^{p+1+m} g_{j,k}^{s_{jk}} \right) : \ r_{jk}, s_{jk} \in \{1, \ldots, l+1\} \right\}
\]

\[
\tilde{T}_j = \frac{1}{h_{p+1+j,1}} \tilde{T}_1, \quad j = 2, 3, \ldots, m
\]

where \( L \) is defined in (147) and the cardinalities of all \( T_i \) sets are the same and are denoted as \( \tilde{M} = (l+1)^\theta \). Also, it is easy to check that since pair \((p+1+j, 1) \notin L\) for \( j \geq 2\), we must have

\[
\tilde{T}_i \cap \tilde{T}_j = \phi
\]

for all \( i \neq j \).

We first focus on receiver 1, which has the channel output

\[
y_1 = \sum_{i=1}^{p+1+m} h_{i1} x_1 + n_1
\]

Substituting (152), (153) and (154) into (158), we get

\[
y_1 = h_{11} x_1 + \sum_{j=2}^{p+1} h_{j1} x_j + \sum_{k=p+2}^{p+1+m} h_{k1} x_k + n_1
\]

\[
= h_{11} \left( \sum_{i=1}^{m} \mathbf{v}_{1i}^T \mathbf{t}_{1i} \right) + \left( \sum_{j=2}^{p+1} h_{j1} \mathbf{v}_{j1}^T \mathbf{t}_{j1} \right) + \left( \sum_{k=p+2}^{p+1+m} h_{k1} \mathbf{u}_{k-p-1}^T \mathbf{t}_{(k-p-1)} \right) + n_1
\]

\[
= \left( \mathbf{v}_{11}^T h_{11} \mathbf{t}_{11} \right) + \left( \mathbf{v}_{12}^T h_{11} \mathbf{t}_{12} \right) + \ldots + \left( \mathbf{v}_{1m}^T h_{11} \mathbf{t}_{1m} \right)
\]

\[
+ \left( \sum_{j=2}^{p+1} h_{j1} \mathbf{v}_{j1}^T \mathbf{t}_{j1} \right) + \left( \sum_{k=p+2}^{p+1+m} h_{k1} \mathbf{u}_{k-p-1}^T \mathbf{t}_{(k-p-1)} \right) + n_1
\]

Since \( \mathbf{v}_{ij} \) and \( \mathbf{u}_{k-p-1} \) are integer signals in \( C(a, Q) \), it suffices to study their dimensions. In addition, note that \( \mathbf{t}_{ij} \) and \( \mathbf{t}_{(j)} \) represent the same dimensions in \( T_j \) defined in (146) and (148). It is easy to verify that

\[
h_{j1} T_1 \subseteq \tilde{T}_1, \quad j = 2, \ldots, p + 1
\]

\[
h_{k1} T_{k-p-1} \subseteq \tilde{T}_1, \quad k = p + 2, \ldots, p + 1 + m
\]

which implies that except the intended message signals \( \mathbf{v}_{1i}, \ i = 1, \ldots, m \), all unintended
signals including message signals and cooperative jamming signals are all transmitted in the dimensions belonging to $\tilde{T}_1$. On the other hand, for intended signals,

$$h_{11}T_i \subseteq h_{11}\tilde{T}_i = \frac{h_{11}}{h_{p+1+i,1}}\tilde{T}_i, \quad i = 2, \ldots, m$$  \hfill (165)

Note that the pair $(p + 1 + i, 1) \not\in L$ for $i \geq 2$ which implies that

$$h_{11}\tilde{T}_i \cap h_{11}\tilde{T}_j = \phi$$  \hfill (166)

for all $i, j \in \{1, \ldots, m\}$, $i \neq j$. Furthermore, $(1, 1) \not\in L$ either, which implies that

$$h_{11}\tilde{T}_i \cap \tilde{T}_1 = \phi, \quad i \in \{1, \ldots, m\}$$  \hfill (167)

Together with (166), this indicates that the dimensions are separable as suggested by the parentheses in (161) and also the $Y_1$ side of Figure 7, which further implies that all the elements in the set

$$R_1 \triangleq \left( \bigcup_{j=1}^{m} h_{11}\tilde{T}_j \right) \cup \tilde{T}_1$$  \hfill (168)

are rationally independent, and thereby the cardinality of $R_1$ is

$$M_R \triangleq |R_1| = (m + 1)\bar{M} = (m + 1)(l + 1)^\theta$$  \hfill (169)

For the legitimate receivers $Y_i, i = 2, \ldots, p + 1$, without loss of generality, we focus on receiver 2; by symmetry, a similar structure will exist at all other receivers. We observe that

$$y_2 = h_{12}x_1 + \sum_{j=2}^{p+1} h_{j2}x_j + \sum_{k=p+2}^{p+1+m} h_{k2}x_k + n_2$$  \hfill (170)

$$= h_{12} \left( \sum_{i=1}^{m} v_{11}^T t_{1i} \right) + \left( \sum_{j=2}^{p+1} h_{j2}v_{j1}^T t_{j1} \right) + \left( \sum_{k=p+2}^{p+1+m} h_{k2}u_{k-p-1}^T t_{(k-p-1)} \right) + n_2$$  \hfill (171)

$$= (h_{22}v_{21}^T t_{21}) + (v_{11}^T h_{12}t_{11} + \sum_{j=3}^{p+1} v_{j1}^T h_{j2}t_{j1} + u_1^T h_{p+2,2}t_{(1)})$$

$$+ (v_{12}^T h_{12}t_{12} + u_2^T h_{p+3,2}t_{(2)}) + \ldots + (v_{1m}^T h_{12}t_{1m} + u_m^T h_{p+1+m,2}t_{(m)}) + n_2$$  \hfill (172)

Similarly, we observe that in the second set of parentheses of (172), since $t_{i1}$ and $t_{(1)}$ represent the same dimensions in $T_1$ for all $i$, we have

$$h_{i2}T_1 \subseteq \tilde{T}_1, \quad i \in \{1, \ldots, p + 2\}, i \neq 2$$  \hfill (173)
Starting from the third set of parentheses of (172), we have

\[ h_{12} T_j \subseteq \tilde{T}_j \quad (174) \]
\[ h_{p+1+j,2} T_j \subseteq \tilde{T}_j \quad (175) \]

for all \( j = 2, \ldots, m \). In addition, since the pair \( (2, 2) \not\in L \), we can infer that

\[ h_{22} T_1 \subseteq h_{22} \tilde{T}_1 \quad (176) \]

and

\[ h_{22} \tilde{T}_1 \cap \tilde{T}_j \quad (177) \]

for \( j = 1, \ldots, m \). Together with (157), this indicates that the dimensions are separable as suggested by the parentheses in (172) and also the \( Y_2 \) side of Figure 7, which further implies that all the elements in the set

\[ R_2 \triangleq \left( \bigcup_{j=1}^{m} \tilde{T}_j \right) \cup h_{22} \tilde{T}_1 \quad (178) \]

are rationally independent, and thereby the cardinality of \( R_2 \) is \( M_R \) in (169).

For the external eavesdropper \( Z_k \), we note that

\[
\begin{align*}
z_k &= g_{1k} x_1 + \sum_{j=2}^{p+1} g_{jk} x_j + \sum_{i=p+2}^{p+1+m} g_{ik} x_i + n_{zk} \\
&= g_{1k} \left( \sum_{i=1}^{m} v_{1i}^T t_{i1} \right) + \left( \sum_{j=2}^{p+1} g_{jk} v_{j1}^T t_{j1} \right) + \left( \sum_{i=p+2}^{p+1+m} g_{ik} u_{i-p-1}^T t_{(i-p-1)} \right) + n_{zk} \\
&= \left( v_{11}^T g_{1k} t_{11} + \sum_{j=2}^{p+1} v_{j1}^T g_{jk} t_{j1} + u_{1}^T g_{p+2,k} t_{(1)} \right) \\
&\quad + \left( v_{12}^T g_{1k} t_{12} + u_{2}^T g_{p+3,k} t_{(2)} \right) + \ldots + \left( v_{1m}^T g_{1k} t_{1m} + u_{m}^T g_{p+1+m,k} t_{(m)} \right) + n_{zk}
\end{align*}
\]

In the first set of parentheses of (181), since \( t_{i1} \) and \( t_{(1)} \) represent the same dimensions in \( T_1 \) for all \( i \), we have

\[ g_{ik} T_1 \subseteq \tilde{T}_1, \quad i \in \{1, \ldots, p+2\} \quad (182) \]

Starting from the second set of parentheses of (181), we have

\[ g_{1k} T_j \subseteq \tilde{T}_j \quad (183) \]
\[ g_{p+1+j,k} T_j \subseteq \tilde{T}_j \quad (184) \]

for all \( j = 2, \ldots, m \). Due to (157), this indicates that the dimensions are separable as
suggested by the parentheses in (181) and also the $Z$ side of Figure 7, which further implies that all the elements in the set

$$R_Z \triangleq \left( \bigcup_{j=1}^{m} \tilde{T}_j \right)$$

(185)

are rationally independent, and thereby the cardinality of $R_Z$ is $M_{R_Z}$

$$M_{R_Z} \triangleq |R_Z| = m\bar{M} = m(l + 1)^{\theta}$$

(186)

We will compute the secrecy rates achievable with the asymptotic alignment based scheme proposed above by using the following theorem.

**Theorem 12 ([4, Theorem 2])** For $K'$-user interference channels with confidential messages, the following rate region is achievable

$$R_i \geq I(V_i; Y_i) - \max_{j \in K'_{-i}} I(V_i; Y_j^{K'}|V_{-i}^{K'}) \quad i = 1, \ldots, K'$$

(187)

where $V_{-i}^{K'} \triangleq \{V_j\}_{j=1,j\neq i}^{K'}$ and $K'_{-i} = \{1, \ldots, i-1, i+1, \ldots, K'\}$. The auxiliary random variables $\{V_i\}_{i=1}^{K'}$ are mutually independent, and for each $i$, we have the following Markov chain $V_i \rightarrow X'_i \rightarrow (Y'_1, \ldots, Y'_{K'})$.

We can reinterpret Theorem 12 as follows: For the $(p+1)$-user IC-CM-EE with $m$ helpers and $N$ external eavesdroppers, since each independent helper’s contribution is the same as noise to both items in (187), which depend only on marginal distributions, we can treat the $(p+1)$-user IC-CM-EE channel as a $(p+1+N)$-user IC-CM with $N$ new transmitters which keep silent, i.e., $V_i$ and $X'_i$, $i = p+2, \ldots, p+1+N$, are equal to zero, and

$$p(y'_1, \ldots, y'_{p+1+N}|x'_1, \ldots, x'_{p+1+N}) = p(y_1, \ldots, y_{p+1}, z_1, \ldots, z_N|x_1, \ldots, x_{p+1})$$

(188)

where $x'$ and $y'$ are the transmitter and receiver of the $(p+1+N)$-user IC-CM and $x, y, z$ are the entities of the original $(p+1)$-user IC-CM-EE with $m$ helpers and $N$ external eavesdropper.

We thereby first select $V_i$ as

$$V_1 \triangleq a_1$$

(189)

$$V_i \triangleq v_{i1}, \quad i = 2, \ldots, p + 1$$

(190)

where $a_1$ is defined in (151). Then, we evaluate the (187) for $i = 1, \ldots, p + 1$.

For $i = 1$, by Lemma 1 for any $\delta > 0$, if we choose $Q = P_{1\rightarrow z|y_1}^{\pi_1}$ and $a = \frac{\eta_1 P^{1/2}}{Q}$, the probability of error of estimating $V_1$ as $\tilde{V}_1$ based on $Y_1$ can be upper bounded by

$$\Pr(e_1) \leq \exp \left( -\eta_1 P^{\delta} \right)$$

(191)
Furthermore, by Fano’s inequality, we can conclude that

\[
I(V_1; Y_1) \leq I(V_1; \tilde{V}_1)
\]

\[
= H(V_1) - H(V_1|\tilde{V}_1)
\]

\[
\geq \frac{mM(1-\delta)}{M_R + \delta} \left( \frac{1}{2} \log P \right) + o(\log P)
\]

\[
= \frac{m(1-\delta)}{(m+1)(1+\frac{1}{\tau})^\theta + \frac{\delta}{\tau}} \left( \frac{1}{2} \log P \right) + o(\log P)
\]

where \(o(\cdot)\) is the little-o function. This provides a lower bound for the first term in (187) with \(i = 1\).

Next, we need to derive an upper bound for the second item in (187), i.e., the secrecy penalty, for \(i = 1\). For \(j \in \{2, \ldots, p+1\}\), by the Markov chain,

\[
V_1 \rightarrow \left( \sum_{k=1}^{p+1} h_{kj}X_k, V_2^{p+1} \right) \rightarrow Y_j
\]

we have

\[
I(V_1; Y_j|V_2^{p+1}) \leq I \left( V_1; \sum_{k=1}^{p+1} h_{kj}X_k | V_2^{p+1} \right)
\]

\[
= H \left( \sum_{k=1}^{p+1} h_{kj}X_k | V_2^{p+1} \right) - H \left( \sum_{k=1}^{p+1} h_{kj}X_k | V_1^{p+1} \right)
\]

The first term in (198) can be rewritten as

\[
H \left( \sum_{k=1}^{p+1} h_{kj}X_k | V_2^{p+1} \right) = H \left[ \sum_{i=k}^m \left( v_{ik}^T h_{1j} t_{1k} + u_{ik}^T h_{p+1+k,j} t_{(k)} \right) \right]
\]

Note that there are in total \(mM_R\) rational dimensions each taking value from \(C(a, 2Q)\). Regardless of the distribution in each rational dimension, the entropy is maximized by uniform distribution, i.e.,

\[
H \left( \sum_{k=1}^{p+1} h_{kj}X_k | V_2^{p+1} \right) \leq \log \left[ (2Q+1)^{mM} \right] = \frac{mM(1-\delta)}{M_R + \delta} \left( \frac{1}{2} \log P \right) + o(\log P)
\]
The second term in (198) is
\[
H \left( \sum_{k=1}^{p+1} h_{kj} X_k \left| V_1^{p+1} \right. \right) = H \left[ \sum_{i=k}^{m} \left( u_i^T h_{p+1+k,j} t(k) \right) \right] = \log [(2Q + 1)^{mM}] \tag{201}
\]
\[
= \frac{mM(1-\delta)}{M_R + \delta} \left( \frac{1}{2} \log P \right) + o(\log P) \tag{202}
\]
Substituting (200) and (202) into (198), we get
\[
I(V_1; Y_j | V_1^{p+1}) \leq \frac{m(\tilde{M} - M)(1-\delta)}{M_R + \delta} \left( \frac{1}{2} \log P \right) + o(\log P) \tag{203}
\]
We note that
\[
\xi \triangleq \frac{m(\tilde{M} - M)(1-\delta)}{M_R + \delta} = \frac{m(\tilde{M} - M)(1-\delta)}{(m+1)M_R + \delta} \tag{204}
\]
\[
= \frac{m \left[ (l+1)^\theta - l^\theta \right] (1-\delta)}{(m+1)(l+1)^\theta + \delta} \tag{205}
\]
\[
= \frac{m \left[ \sum_{k=0}^{\theta-1} (\theta_k) l^k \right] (1-\delta)}{(m+1)(l+1)^\theta + \delta} \tag{206}
\]
The maximum power of \( l \) in the numerator is \( \theta - 1 \) and is less than the power \( \theta \) of \( l \) in the denominator. This implies that when \( m \) and \( \delta \) are fixed, by choosing \( l \) large enough, the factor before the \( \frac{1}{2} \log P \) term in (203), \( \xi \), can be made arbitrarily small. Due to the non-perfect (i.e., only asymptotical) alignment, the upper bound for the information leakage rate is not a constant as in [2], but a function which can be made to approach zero d.o.f.

Similarly, we can derive the following
\[
I(V_1; Z_k | V_2^{p+1}) \leq \xi \left( \frac{1}{2} \log P \right) + o(\log P) \tag{207}
\]
where \( Z_k, k = 1, \ldots, N, \) is the external eavesdropper. Substituting (195), (203) and (207) into (187), we obtain a lower bound for the achievable secrecy rate \( R_1 \) as
\[
R_1 \geq \left[ \frac{m(1-\delta)}{(m+1) \left( 1 + \frac{1}{\theta} \right)^\theta + \frac{\delta}{\theta^2} - \xi} \right] \left( \frac{1}{2} \log P \right) + o(\log P) \tag{208}
\]
Similarly, it is easy to derive that
\[
R_i \geq \left[ \frac{(1-\delta)}{(m+1) \left( 1 + \frac{1}{\theta} \right)^\theta + \frac{\delta}{\theta^2} - \xi'} \right] \left( \frac{1}{2} \log P \right) + o(\log P) \tag{209}
\]
for \( i = 2, \ldots, p+1 \) and \( \xi' \) can be made arbitrarily small. By choosing \( l \to \infty \) and \( \delta \to 0 \), we
can achieve a s.d.o.f. tuple arbitrarily close to

\[
\left( \frac{m}{m+1}, \frac{1}{m+1}, \ldots, \frac{1}{m+1} \right)
\]

which is (137), completing the proof of Theorem 11.

6 Conclusions

In this paper, we determined the entire s.d.o.f. regions of K-user MAC wiretap channel, K-user IC-EE, K-user IC-CM, and K-user IC-CM-EE. The converse for MAC directly followed from the results in [1, 2]. The converse for IC was shown to be dominated by secrecy constraints and interference constraints in different parts. To show the tightness and achieve the regions characterized by the converses, we provided a general method to investigate this class of channels, whose s.d.o.f. regions have a polytope structure. We provided an equivalence between the extreme points in the polytope structure and the rank of submatrices containing all active upper bounds associated with each extreme point. Then, we achieved each extreme point by relating it to a specific channel model. More specifically, the extreme points of the MAC region can be achieved by an m-user MAC wiretap channel with K − m helpers, i.e., by setting K − m users’ secure rates to zero and utilizing them as pure (structured) cooperative jammers. On the other hand, the asymmetric extreme points of the IC region can be achieved by a (p + 1)-user IC-CM with m helpers, and N external eavesdroppers.

A Proof of Theorem 10

Regarding Theorem 10 first, we have few comments:

1) (135) will not be possible until K ≥ 5 due to the constraint K − 2 ≥ p′ ≥ 3.

2) The point in (135) with p′ = K − 1, i.e., (1/2, 1/2, . . . , 1/2, 0), is actually an extreme point, but since (134) with p = K − 2 also includes it, we classify it as (134) here.

3) Assume that we allow p′ = 2 in (135) with K ≥ 5. Then, the point becomes

\[
d_1 = \left( \frac{1}{2}, \frac{1}{2}, 0, 0, \ldots, 0 \right)
\]

(211)

However, this is just the middle point of two points in (134). More specifically, by choosing p = 1 in (134), we have \(d_1' = (\frac{K-2}{K-1}, 0, 0, \ldots, 0)\) and \(d_1'' = (\frac{1}{K-1}, \frac{K-2}{K-1}, 0, 0, \ldots, 0)\) (by swapping the first two elements in \(d_1'\)). Here \(d_1' \neq d_1''\) due to \(K \geq 5\), and also it
is easy to check that \( d_1 = \frac{1}{2}(d'_1 + d''_1) \), which means that \( d_1 \) is not an extreme point. Therefore, in (135) \( p' \) must satisfy \( p' \geq 3 \).

Now, we start the proof of Theorem 10. In order to speak of a polytope, we re-write (16) as

\[-d_i \leq 0, \quad i = 1, \ldots, K\]  

(212)

Then, we can write all the left hand sides of (14), (15), (212) as an \( N \times K \) matrix \( H \) with corresponding right hand sides forming an \( N \)-length column vector \( h \), i.e., all points \( d \) in \( D \) satisfy

\[ H d \leq h \]  

(213)

where \( N \triangleq 2K + \binom{K}{2} = 2K + K(K - 1)/2 \). For any extreme point \( d \in D \), let \( J(d) \) be a set such that

\[ J(d) = \left\{ l : H_l d = h_l, \quad l \in \{1, \ldots, N\} \right\} \]  

(214)

where \( H_l \) is the \( l \)th row of \( H \) and \( h_l \) is the \( l \)th element of \( h \). Therefore, \( J(d) \) represents all active boundaries. The remaining rows satisfy

\[ H_l d < h_l \]  

(215)

for \( l \notin J \).

For convenience, denote by \( H_J \) the sub-matrix of \( H \) with rows indexed by \( J \triangleq J(d) \). Similarly denote by \( h_J \) the sub-vector of \( h \) with rows indexed by \( J \). In order to find all extreme points in \( D \), by Theorem 7 in Section 3.1, we need to find all \( K \times (K + 1) \) sub-matrices \( (H', h') \) of \( (H, h) \) with \( \text{rank}(H') = K \) such that \( H d \leq h \) and \( H' d = h' \), which is also equivalent to finding all index sets \( J \) representing the active boundaries such that \( H d \leq h, H_J d = h_J \), and \( \text{rank}(H_J) = K \).

For convenience of presentation, we always partition the set \( J \) as a union of mutually exclusive sets \( S, P \) and \( Z \), i.e.,

\[ J = S \cup P \cup Z \]  

(216)

We denote by \( S \) the row indices representing the active boundaries in (14)

\[ S \triangleq \left\{ s_i \triangleq s(i) : H_{s_i} d = h_{s_i} \text{ is } (K - 1)d_i + \sum_{j=1}^{K} d_j = K - 1, \quad i = 1, \ldots, K \right\} \]  

(217)

where \( s_i \) stands for the function \( s(i) \) of the coordinate \( i \) with the value as the row index of \( H \) corresponding to the active boundaries \( (K - 1)d_i + \sum_{j=1}^{K} d_j = K - 1 \). Thus, we have a
one-to-one mapping between the row index and the function \( s_i \triangleq s(i) \), i.e., if the row index \( s_i \in J \), we know exactly the \( i \)th upper bound in (14) is active; on the other hand, if we know the coordinate \( i \), we can determine the unique corresponding row index in \( \mathbf{H} \) by the mapping \( s: i \mapsto s_i \).

Similarly, we denote by \( P \) the row indices representing the active boundaries in (15)

\[
P \triangleq \left\{ p_V \triangleq p(V) : \mathbf{H}_{p_V} \mathbf{d} = h_{p_V} \text{ is } \sum_{i \in V} d_i = 1, \ V \subseteq \{1, \ldots, K\}, |V| = 2 \right\}
\]  

(218)

where the value of \( p_V \) is the corresponding row index of \( \mathbf{H} \).

Finally, we denote by \( Z \) the row indices representing the active boundaries in (212)

\[
Z \triangleq \left\{ z_i \triangleq z(i) : \mathbf{H}_{z_i} \mathbf{d} = h_{z_i} \text{ is } d_i = 0, \ i = 1, \ldots, K \right\}
\]  

(219)

where the value of \( z_i \) is the corresponding row index of \( \mathbf{H} \).

There are approximately in total

\[
\binom{N}{K} \approx \frac{(K+2)^K e^K}{\sqrt{2\pi K}}
\]  

(220)

possible selections of \( K \) equations in (213) for large \( K \). In order for this search to have a reasonable complexity, we need to investigate the structure of \( D \) more carefully. We identify the following simple properties for the extreme points in the following lemmas.

**Lemma 2** Let \( \mathbf{d} \) be a non-zero extreme point in \( D \). Then, it must satisfy the following properties:

1) \( \max_k d_k \leq \frac{K-1}{K} \).

2) At most one element, if there is any, in \( \mathbf{d} \) is strictly larger than \( \frac{1}{2} \).

3) If there exists an element, say \( d_i \), which is equal to \( \frac{1}{2} \), then, \( d_j \leq d_i = \frac{1}{2} \) for all \( j \).

4) If \( |S| \geq 2 \) and \( \forall s_i, s_j \in S \), where \( i \neq j \), then \( 0 < d_i = d_j \leq \frac{1}{2} \).

5) If \( s_i \in S \), then \( d_j \leq d_i \) for all \( j \). Equivalently, if \( |S| \geq 1 \) and \( s_i \in S \), then \( d_i = \max_{j=1,\ldots,K} d_j \). Equivalently, if \( |S| \geq 1 \) and \( d_i = \max_{j=1,\ldots,K} d_j \), then \( s_i \in S \).

6) If \( \max_i d_i > \frac{1}{2} \), then \( |S| \leq 1 \).

The proof of Lemma 2 is provided in Appendix B. In addition to the properties of the elements of the extreme points, we also need some results regarding the rank of the sub-matrices. It is easy to verify that a trivial necessary condition for \( \text{rank}(\mathbf{H}_J) = K \) is \( |S| + |P| + |Z| \geq K \). More formally, we have the following lemma.

**Lemma 3** For an extreme point \( \mathbf{d} \), \( \text{rank}(\mathbf{H}_J) = K \) only if

\[ \text{rank}(\mathbf{H}_{S \cup P}) + |Z| \geq K \]  

(221)
Lemma 4 Let $d$ be a non-zero extreme point of $D$. If $|P| \geq 1$ and $\max_k d_k > \frac{1}{2}$, then there exists a coordinate $i_*$ such that

$$\frac{K-1}{K} \geq d_{i_*} = \max_k d_k > \frac{1}{2}$$  \hfill (222)

and a non-empty set

$$U' \triangleq \{ j : d_j = 1 - d_{i_*} > 0 \}$$  \hfill (223)

with cardinality $m' \triangleq |U'| = |P|$ and

$$P = P' \triangleq \{ p_V : V = \{ i_*, j \}, j \in U' \}$$  \hfill (224)

In addition, $S$ is either empty or

$$S = \{ s_{i_*} \}$$  \hfill (225)

Furthermore,

$$\text{rank}(H_{S \cup P}) = |P| + 1_{\{|S| \geq 1\}}$$  \hfill (226)

where $1_{\{\cdot\}}$ is the indicator function.

Lemma 5 Let $d$ be a non-zero extreme point of $D$. If $|P| \geq 1$ and $\max_k d_k \leq \frac{1}{2}$, then there exists a non-empty set

$$U'' = \{ i : d_i = \frac{1}{2} \}$$  \hfill (227)

with cardinality $m'' \triangleq |U''|$, $2 \leq m'' \leq K - 1$, and

$$P = P'' \triangleq \{ p_V : V = \{ k, j \}, k \neq j, \text{ and } k, j \in U'' \}$$  \hfill (228)

with rank

$$\text{rank}(H_P) = \begin{cases} m'', & |P| > 1 \\ 1, & |P| = 1 \end{cases}$$  \hfill (229)

In addition, $S$ is either empty or

$$S = \{ s_i : i \in U'' \}$$  \hfill (230)

Furthermore,

$$\text{rank}(H_{S \cup P}) = \begin{cases} 1, & |P| = 1 \text{ and } |S| = 0 \\ m'' + 1_{\{|S| \geq 1\}}, & \text{o.w.} \end{cases}$$  \hfill (231)

where $1_{\{\cdot\}}$ is the indicator function.

The proofs of Lemmas 3, 4, and 5 are provided in Appendix B.
Case: $|Z| = K$. Clearly, $\text{rank}(H_Z) = K$ and only the zero vector satisfies

$$H0 \leq h$$

$$H_Z0 = h_Z$$

Thus, 0 is an extreme point of $D$, which is (133). Therefore, in the remaining discussion we focus on non-zero points and $|Z| < K$.

Case: $|P| = 0$. Since $|Z| < K$, by Lemma 3, $|S| \geq 1$.

If $|S| = 1$, then again by Lemma 3, $|Z| = K – 1$. By property 5 of Lemma 2 $S = \{s_i\}$ for some $i$ and $Z = \{z_j : j \neq i\}$. The extreme point $\mathbf{d}$ has the structure (134) with $p = 0$.

If $|S| = K$, then by property 4 of Lemma 2, $Z = \phi$, and the corresponding extreme point is (136).

If $2 \leq |S| \leq K – 1$, due the positiveness implied by property 4 of Lemma 2 and the cardinality constraint by Lemma 3, the only consistent $Z$, which gives a solution for $H_J\mathbf{d} = h_J$, is

$$Z = \{z_j : s_j \notin S\}$$

Denote by $x$ any $d_i$ for $s_i \in S$. Then, we have

$$Kx + (|S| – 1)x = K – 1$$

which implies that

$$x = \frac{K – 1}{K – 1 + |S|}$$

Since $P$ is empty, $x$ must satisfy $x < \frac{1}{2}$ due to $|S| \geq 2$ and property 4 of Lemma 2. Substituting (236) into $x < \frac{1}{2}$ gives $|S| > K – 1$, which contradicts the assumption $|S| < K$. Therefore, the solution given by $H_J\mathbf{d} = h_J$, where $J = S \cup Z$, violates (215).

Case: $|P| \geq 1$ and $\max_k d_k > \frac{1}{2}$. First of all, due to the positiveness implied by (222) and (223), the consistent set $Z$ must satisfy

$$Z \subseteq \{z_k : k \notin \{i_s\} \cup U'\}$$

which implies $|Z| \leq K – |U'| – 1 = K – |P| – 1$.

If $S$ is empty, by Lemma 4, $\text{rank}(H_{S \cup P}) = |P|$, which implies

$$\text{rank}(H_{S \cup P}) + |Z| < K$$

which implies that $\text{rank}(H_J) < K$, which does not give any extreme point, by Lemma 3.

Therefore, $S$ is non-empty and determined by (225). In addition, Lemma 4 gives

$$\text{rank}(H_{S \cup P}) = |P| + 1$$

45
If $|P| = K - 1$, due to (223) and (225), we have the equality in (14) hold for $i^*$, i.e.,

$$Kd_{i^*} + (K - 1)(1 - d_{i^*}) = K - 1$$

(240)

which leads to $d_{i^*} = 0$ contradicting (222).

Therefore, $|P| < K - 1$. Then, the consistent set $Z$ satisfying Lemma 3 is

$$Z = \left\{ z_k : k \notin \{i^* \} \cup U' \right\}$$

(241)

In addition, due to (223) and (225), we have the equality in (14) hold for $i^*$, i.e.,

$$Kd_{i^*} + |P|(1 - d_{i^*}) = K - 1$$

(242)

which implies that

$$d_{i^*} = \frac{K - 1 - |P|}{K - |P|}$$

(243)

Since $d_{i^*} = \max_k d_k > \frac{1}{2}$, we have

$$|P| < K - 2$$

(244)

The solution of this choice is exactly (134) with $1 \leq p < K - 2$, and it satisfies (213).

Case: $|P| \geq 1$ and $\max_k d_k \leq \frac{1}{2}$. If $S$ is empty, then by Lemma 5

$$\text{rank}(H_{S \cup P}) = \begin{cases} m'', & |P| > 1 \\ 1, & |P| = 1 \end{cases}$$

(245)

where $m''$ is the cardinality of $U''$ defined in (227). Since $m'' \geq 2$, for both cases, $\text{rank}(H_{S \cup P}) \leq m''$. Due to the positiveness of the elements in $U''$, $|Z| \leq K - m''$. Therefore, by Lemma 3 the cardinality of $Z$ can only take the value $|Z| = K - m''$, i.e.,

$$d_j = 0, \quad \forall j \notin U''$$

(246)

Also, Lemma 3 implies that $|P| > 1$ and $m'' > 2$; otherwise, $\text{rank}(H_{S \cup P}) + |Z| = 1 + |Z| \leq 1 + K - m'' \leq K - 1 < K$.

Therefore, the elements in $d$ are either $\frac{1}{2}$ or 0, and the number of $\frac{1}{2}$'s is $m''$. Note that $S$ is empty. Therefore, for any $i \in U''$, we must have the equality in (14) not hold, i.e.,

$$\frac{K}{2} + (m'' - 1)\frac{1}{2} < K - 1$$

(247)

which indicates that

$$m'' < K - 1$$

(248)
Combining with the condition \( m'' > 2 \) gives an extreme point that has the structure (135).

It remains to discuss the case where \( S \) is non-empty. By Lemma 5, \( S \) is determined by (230) and

\[
\text{rank}(H_{S \cup P}) = m'' + 1
\]  

If \( m'' = K - 1 \), then the only solution is given by choosing \( Z = \{ z_j : j \notin U'' \} \) with \( |Z| = 1 \), which is the structure in (134) with \( p = K - 2 \).

If \( m'' < K - 1 \), then \( \text{rank}(H_{S \cup P}) < K \). By Lemma 3 and the positiveness implied by \( U'' \) with cardinality \( m'' \), \( Z \) must satisfy

\[
K - m'' \geq |Z| \geq K - \text{rank}(H_{S \cup P}) = K - m'' - 1 > 0
\]  

i.e., \( Z \) is not empty and the extreme point \( d \) has either \( K - m'' - 1 \) or \( K - m'' \) zero(s). On the other hand, \( d \) also has in total \( m'' \frac{1}{2^s} \) due to the definition of \( U'' \) in (227). If \( |Z| = K - m'' \), then the extreme point \( d \) has the following form

\[
d_i = \begin{cases} 
\frac{1}{2} & i \in U'' \\
0 & i \notin U'' 
\end{cases}
\]  

and we must have the equality in (14) hold for some \( i \in U'' \), i.e.,

\[
\frac{K}{2} + (m'' - 1)\frac{1}{2} = K - 1
\]  

which is not valid since \( m'' < K - 1 \). Therefore, the equations corresponding to the selection of \( J \) are inconsistent. On the other hand, if \( |Z| = K - m'' - 1 \), then the extreme point \( d \) has the following form

\[
d_i = \begin{cases} 
\frac{1}{2} & i \in U'' \\
0 & z_i \in Z \\
x & \text{o.w.}
\end{cases}
\]  

where \( 0 < x < \frac{1}{2} \). Again, we must have the equality in (14) hold for some \( i \in U'' \), i.e.,

\[
\frac{K}{2} + (m'' - 1)\frac{1}{2} + x = K - 1
\]  

which implies that

\[
x = \frac{K - 1 - m''}{2}
\]  

Substituting this formula into \( 0 < x < \frac{1}{2} \) leads to

\[
K - 2 < m'' < K - 1
\]  

which is not possible since \( m'' \) is an integer, which completes the proof of Theorem 10.
B Proofs of Lemma 2 through 5

B.1 Proof of Lemma 2

We prove all the properties one by one.

1) The constraint (14) and the positiveness constraint in (16) imply that for any coordinate \( i \), we have

\[
Kd_i \leq Kd_i + \sum_{j \neq i} d_j = K - 1
\]

i.e., \( d_i \leq \frac{K-1}{K} \) for any \( i \). Therefore, \( \max_k d_k \leq \frac{K-1}{K} \).

2) We prove by contradiction. Assume that we have distinct coordinates, \( i, j \), such that \( d_i, d_j > \frac{1}{2} \) in \( d \). Then, the set \( V \triangleq \{i, j\} \) with \( |V| = 2 \) violates the constraint in (15). Therefore, this contradiction implies that at most one element, if any, in \( d \) is strictly larger than \( \frac{1}{2} \).

3) Similarly, assume that there exists a \( j \) such that \( d_j > \frac{1}{2} \). Since \( d_i = \frac{1}{2} \) by assumption, \( d_i + d_j > 1 \), which violates constraint (15). This implies that \( d_j \leq d_i = \frac{1}{2} \) for all \( j \).

4) Let \( i, j \in S \) and \( i \neq j \). Due to the definition of \( S \), \( s_i, s_j \in S \), i.e., from (217)

\[
Kd_i + d_j + \sum_{k=1, k \neq i, j}^K d_k = K - 1
\]

\[
Kd_j + d_i + \sum_{k=1, k \neq i, j}^K d_k = K - 1
\]

which implies \((K - 1)d_i = (K - 1)d_j\). Since \( K - 1 > 0 \), \( d_i = d_j \). Furthermore, due to property 2), both are no larger than \( \frac{1}{2} \), and due to property 3), for any \( k \), \( d_k \leq d_i \). If \( d_i = 0 \), then the point \( d \) is the zero vector, which contradicts the assumption that \( d \) is a non-zero extreme point in \( D \). Therefore, \( d_i = d_j > 0 \).

5) The three equivalent statements in this property are simply from three different perspectives addressing the same fact that the coordinates of \( d \), which are associated with the elements in \( S \), are the most significant coordinates. We will prove the first statement and then prove the equivalence of all three statements.

We prove the first statement of property 5) by contraction. Assume that there exists a \( j \)}
such that \( d_j > d_i \). Then, consider the following expression (for \( K \geq 3 \))

\[
Kd_j + d_i + \sum_{k=1, k \neq i, j}^{K} d_k = d_j + d_i + (K - 1)d_j + \sum_{k=1, k \neq i, j}^{K} d_k > d_j + d_i + (K - 1)d_i + \sum_{k=1, k \neq i, j}^{K} d_k
\]  

\[
= Kd_i + \sum_{k=1, k \neq i}^{K} d_k 
\]  

\[
= K - 1
\]  

where the last equality is due to the assumption \( s_i \in S \). This result violates the constraint (14). Therefore, for all \( j \), \( d_j \leq d_i \).

Next, we prove the second statement of property 5) using the first statement. This is trivially true because the assumption \( |S| \geq 1 \) and \( s_i \in S \) imply that, by the first statement, \( d_i \geq d_j \) for all \( j \), i.e., \( d_i = \max_j d_j \).

Then, we prove the third statement of property 5) using the second statement. By assumption, let \( d_i = \max_k d_k \). However, assume that \( s_i \notin S \). This implies that there exists another coordinate \( j \), \( j \neq i \) such that \( s_j \in S \) (since \( |S| \geq 1 \)) and thereby by the second statement \( d_j = \max_k d_k = d_i \). Then, consider

\[
Kd_i + d_j + \sum_{k=1, k \neq i, j}^{K} d_k = Kd_j + d_i + \sum_{k=1, k \neq i, j}^{K} d_k = K - 1
\]

where the last equality is due to \( s_j \in S \). This implies that \( s_i \) must belong to \( S \) by definition in (217), i.e., \( s_i \in S \), which contradicts the assumption that \( s_i \notin S \).

Finally, we prove the first statement of property 5) using the third statement. We prove this by contradiction as well. As stated in the condition of the first statement, \( s_i \in S \), this means \( |S| \geq 1 \). Assume that there exists at least one element which is strictly larger than \( d_i \). Choose the largest one among them and denote it by \( d_j \). Clearly, \( j \neq i \) and \( d_j = \max_k d_k > d_i \). By the third statement, \( s_j \in S \). Then, \( |S| \geq 2 \) and by property 4) \( d_i = d_j \), which contradicts the assumption \( d_j > d_i \).

6) We prove \( |S| \leq 1 \) by contraction. Assume that \( |S| \geq 2 \). Due to property 4) and the second statement of property 5), we have two distinct \( j, k \in S \) such that \( \frac{1}{2} \geq d_j = d_k = \max_i d_i > \frac{1}{2} \), which leads to a contradiction. Thus, \( |S| \leq 1 \).

**B.2 Proof of Lemma 3**

It is straightforward that

\[
\text{rank}(H_Z) = |Z|
\]  

(265)
since there are in total \(|Z|\) 1s in the sub-matrix \(H_Z\) and the row index and column index of any two 1s are different. Since \((S \cup P) \cap Z = \phi\), we have

\[
K = \text{rank}(H_J) = \text{rank}(H_{S \cup P \cup Z}) \leq \text{rank}(H_{S \cup P}) + \text{rank}(H_Z)
\]

(266)

### B.3 Proof of Lemma 4

If \(|P| = 1\), then \(P = \{p_V\}\) for a unique \(V = \{i, j\}\) with \(|V| = 2\). If \(d_i = d_j\), then \(d_i = d_j = \frac{1}{2}\) and \(\max_k d_k \leq \frac{1}{2}\) due to property 3 of Lemma 2, which contradicts the condition \(\max_k d_k > \frac{1}{2}\). Therefore, \(d_i \neq d_j\). Without loss of generality, let \(d_i > d_j\), then \(d_i > \frac{1}{2}\) and \(i\) is the \(i_*\) required in Lemma 4 due to property 2 of Lemma 2. By property 1 of Lemma 2, \(d_j = 1 - d_{i_*} > 0\), thus \(j \in U'\). If there exists any \(k\), \(k \neq j\), such that \(d_k = 1 - d_{i_*}\), then clearly \(V' \nsubseteq \{i_*, k\} \neq V\), but \(p_V \in P\), which contradicts the condition \(|P| = 1\). Hence, \(U' = \{j\}\) and \(P\) satisfies (224).

If \(|P| \geq 2\), assume that \(V_1 = \{i, j\}\), \(V_2 = \{x, y\}\), \(V_1 \neq V_2\), and \(p_{V_1}, p_{V_2} \in P\). Without loss of generality, let \(d_i = \max_{k \in \{i, j, x, y\}} d_k\). If \(d_i < \frac{1}{2}\), then \(d_j + d_i < 1\), which contradicts \(p_{V_1} \in P\). If \(d_i = \frac{1}{2}\), then due to property 3 of Lemma 2, \(\max_k d_k \leq \frac{1}{2}\), which contradicts the condition \(\max_k d_k > \frac{1}{2}\). Therefore, \(d_i = \max_{k \in \{i, j, x, y\}} d_k > \frac{1}{2}\) and \(i\) is the \(i_*\) required in Lemma 4. For any \(p_V \in P\), let \(V = \{a, b\}\) and assume \(d_a \geq d_b\). If \(d_a = \frac{1}{2}\), this leads to a contradiction of \(d_{i_*} > \frac{1}{2}\) due to property 3 of Lemma 2. Thus, \(d_a > \frac{1}{2}\). Due to property 2 of Lemma 2, the coordinate \(a\) must be \(i_*\), i.e., \(a = i_*\). Then, \(d_b = 1 - d_{i_*} > 0\) and that is true for any \(p_V\). Hence, \(|P| = |U'|\) and (224) are trivially true.

If \(S\) is empty, we have a sub-matrix which has the form (by removing all columns containing all zeros and rearranging the columns)

\[
H_{S \cup P} = H_P = \begin{bmatrix} 1 & 1 & 0 & 0 & \ldots & 0 \\ 1 & 0 & 1 & 0 & \ldots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 0 & 0 & 0 & \ldots & 1 \end{bmatrix} \tag{267}
\]

where the number of rows is \(|P| = |U'|\), the number of columns is \(|P| + 1\), and the index of the first column corresponds to \(i_*\) and the indices of other columns correspond to \(U'\) defined in (223). Therefore, \(\text{rank}(H_{S \cup P}) = |P|\) and we are done.

If \(S\) is not empty, due to (222) and property 0 of Lemma 2, \(|S| = 1\). Furthermore, due to property 5 of Lemma 2, \(s_{i_*} \in S\), which is (225). Note that \(H_S\) is a \(K\)-length row vector containing no zeros. If \(|P| + 1 < K\), then \(H_S\) has more columns than the sub-matrix on the
right hand side of (267). \( H_{S \cup P} = |P| + 1 \) is true. If \(|P| + 1 = K\), then

\[
H_{P \cup S} = \begin{bmatrix}
1 & 1 & 0 & 0 & \ldots & 0 \\
1 & 0 & 1 & 0 & \ldots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
1 & 0 & 0 & 0 & \ldots & 1 \\
K & 1 & 1 & 1 & \ldots & 1
\end{bmatrix} \triangleq M(K)
\] (268)

where \( M(n) \) is \( n \times n \) square matrix as in (268), where \( n \geq 2 \). Therefore, \( H_{P \cup S} = M(K) \). If we denote \( f(n) \triangleq \det[M(n)] \), then it is easy to write the recursive formula as

\[
f(n) = (-1)^n - f(n-1), \quad n \geq 3 \quad (269)
\]

\[
f(2) = 1 - K \quad (270)
\]

which gives that \( f(n) = (-1)^n(n - K - 1) \), i.e., \( \det H_{P \cup S} = \det M(K) = (-1)^{K+1} \neq 0 \) and \( \text{rank}(H_{P \cup S}) = |P| + 1 = K \), which completes the proof.

**B.4 Proof of Lemma 5**

If \( \max_k d_k < \frac{1}{2} \), then \( |P| = 0 \), which contradicts the assumption \(|P| \geq 1 \). Therefore, \( \max_k d_k = \frac{1}{2} \), which implies \(|U''| \geq 1 \). Assume that \( i_* \in U'' \). Due to property 3) of Lemma 2, \( d_j \leq d_{i_*} = \frac{1}{2} \) for all \( j \). If \( \max_{k \neq i_*} d_k < \frac{1}{2} \), then we cannot find a set \( V \) such that \(|V| = 2 \) and \( \sum_{k \in V} d_k = 1 \), i.e., \(|P| = 0 \), which contradicts the assumption \(|P| \geq 1 \). Thus, \( m'' \triangleq |U''| \geq 2 \). On the other hand, if \( m'' = K \), by definition of \( U'' \), all elements in \( d \) are \( \frac{1}{2} \), which violates the constraint (14). Therefore, \( m'' \leq K - 1 \).

Next, \( P'' \) defined in (228) satisfies \( P'' \subseteq P \). On the other hand, for any coordinate pair \((k', j')\) such that \( k' \neq j' \) and \( p_{(k', j')} \in P \), since \( d_{k'} d_{j'} \leq \frac{1}{2} \), we must have \( d_{k'} = d_{j'} = \frac{1}{2} \), and by definition of \( U'' \), \( k', j' \in U'' \), which implies \( p_{(k', j')} \in P'' \). Therefore, \( P = P'' \).

If \( S \) is empty, then \( H_P = 1 \) if \(|P| = 1 \) and we are done. If \( S \) is empty but \(|P| > 1 \), the index set of the columns of \( H_P \), which contains nonzero elements, is \( U'' \) due to (228). Therefore, \( \text{rank}(H_P) \leq |U''| = m'' \). In order to study the rank, we remove the columns containing all zeros and rearrange the columns. Assume that

\[
U'' = \{i_1, i_2, \ldots, i_{m''}\}
\] (271)
where $i_1 = i_*$. Then, consider a $m'' \times m''$ sub-matrix of $H_P$

\[
H_{J''} \doteq \begin{bmatrix}
1 & 1 & 0 & 0 & 0 & \ldots & 0 \\
1 & 0 & 1 & 0 & 0 & \ldots & 0 \\
1 & 0 & 0 & 1 & 0 & \ldots & 0 \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
1 & 0 & 0 & 0 & 0 & \ldots & 1 \\
0 & 1 & 1 & 0 & 0 & \ldots & 0
\end{bmatrix}
\] (272)

where

\[
J'' \triangleq \{p_V : V = \{i_*, i_j \}, j = 2, \ldots, m'' \} \cup \{p_{\{i_2, i_3 \}} \} \subseteq P
\] (273)

It is easy to verify that $\det H_{J''} = (-1)^m2 \neq 0$, therefore $\text{rank}(H_{J''}) = m''$, i.e., $\text{rank}(H_P) = m''$. This completes the proof of the case where $S$ is empty.

Assume that $|S| \geq 1$, by property 5) of Lemma 2, $S$ must have the form of (230). If $|P| = 1$, $m'' = |U''| = 2$. Then, the $3 \times K$ matrix $H_{P\cup S}$ must have the structure

\[
H_{P\cup S} = \begin{bmatrix}
1 & 1 & 0 & 0 & 0 & \ldots & 0 \\
K & 1 & 1 & 1 & 1 & \ldots & 1 \\
1 & K & 1 & 1 & 1 & \ldots & 1
\end{bmatrix}
\] (274)

where the indices of the first two columns belong to $U''$. Clearly, $H_{P\cup S} = 3 = m'' + 1$ since $m'' = 2$.

If $|P| > 1$, by using the $J''$ in (273) and the condition $m'' \leq K - 1$, we have

\[
H_{J''\cup S} = \begin{bmatrix}
1 & 1 & 0 & 0 & \ldots & 0 & 0 & 0 & \ldots & 0 \\
1 & 0 & 1 & 0 & \ldots & 0 & 0 & 0 & \ldots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\
1 & 0 & 0 & 0 & \ldots & 0 & 1 & 0 & \ldots & 0 \\
0 & 1 & 1 & 0 & \ldots & 0 & 0 & 0 & \ldots & 0 \\
K & 1 & 1 & 1 & \ldots & 1 & 1 & 1 & \ldots & 1 \\
1 & K & 1 & 1 & \ldots & 1 & 1 & 1 & \ldots & 1 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\
1 & 1 & 1 & 1 & \ldots & K & 1 & 1 & \ldots & 1 \\
1 & 1 & 1 & 1 & \ldots & 1 & K & 1 & \ldots & 1
\end{bmatrix}
\] (275)

Due to [54, Section 2.2, Problem 7],

\[
\text{rank}(H_{P\cup S}) = \text{rank}(H_{J''\cup S}) = \text{rank}(H_{J''}) + 1 = m'' + 1
\] (276)

which completes the proof.
