Original Research Article

ABSTRACT

"Childhood Obesity and its co-morbidities is considered as a prime health hitch that lay up consideration among the public health society. Obesity and above the over weight has bagged the fifth position in the global risk for mortality. The Obesity shows a very early onset in life which has laid the utmost importance in the prevention of it among the children. Neck circumference is being considered as the marker of upper body subcutaneous tissue distribution.

Aim: The main objective is to evaluate the association between neck circumference and obesity among the children.

Methodology: This is a cross sectional study conducted between the periods of August 2019 - September 2019, among 150 males + 129 females students, aged 11 to 18 years. Anthropometric markers of obesity- body mass index (BMI), waist circumference (WC), Hip circumference (HC), waist hip ratio (WHR), neck circumference (NC) were collected. Pearson's correlation coefficient was used to compute the neck circumference with other obesity indices.

Results: The mean BMI was 27.70±1.27 kg/m² and 27.72±2.12 kg/m², mean neck circumference was 35.42±2.26 cm and 32.85±1.92 in above the over weight /obesity boys + girls respectively. The hip circumference in boys was found to be greater than girls, which is higher in above the over weight /obesity students with P<0.001. Neck circumference shows a strong positive correlation with other anthropometric measures BMI, WC, HC in boys and girls (P<0.001).
Conclu
s
ion: The present study showed that the weight increase in school children and need to
aware the parents.

Keywords: BMI; NC; above the over weight; obesity; WC; HC; children.

1. INTRODUCTION

Above the over weight is defined as body mass index between 25 and 29.9 kilogram per meter
square and obesity is defined as BMI of 30 kilogram per meter square or higher. Obesity is a
pathological condition in which excess body fat accumulated, leading adverse effects on health
and life expectancy [1]. It is a chronic disorder with complex interaction between genetic and
environmental factors. It characterized by high cholesterol, fatty acid levels; imbalance in
metabolic energy; insulin desensitization; lethargy, gallstones; high blood pressure;
shortness of breath; emotional and social problems; and excessive adipose mass
accumulation with hyperplasia and hypertrophy [2]. Pathological obesity is associated with
several secondary commodities like heart disease, type 2 diabetes, breathing difficulties
during sleep, cancer and osteoarthritis.

It is most commonly caused by a combination of excessive dietary calories, lack of physical
activity, and genetic susceptibility. Evidence to support this view is that some obesity people eat
little yet gain weight due to slow metabolic rate. The primary treatment for obesity are dieting and
physical exercise. To addion to this, or in case of failure, anti-obesity drugs may be taken to
reduce appetite or impede fat absorption [3]. In serious cases, surgery is carryout or an
intragastric balloon is placed to lower stomach volume and/or bowel length, precede to earlier
satiation and make less ability to absorb nutrients from food [4].

Obesity can be associated with several risk factors such as cardiovascular and metabolic
disturbances. There are numerous methods for assessing above the over weight and
obesity. Some techniques are applicable at primary care facilities, such as measurements of
weight, height, hip circumference, calculations of waist-hip ratio and BMI. It is important to
develop a quick method of for the assessment of obesity in primary care clinic. The purpose
of the study to determine whether neck circumference is useful alone for assessing
obesity [5].

The restraint of BMI as a risk evaluation tool is also conceded, and there is continuing interest in
alternative or complementary indices linking body adiposity and disease risk. For example, some
studies suggest that abdominal circumference is better correlated than BMI with the risk of type 2
diabetes [6]. Although it is well established that visceral adiposity plays a central role in the
metabolic disorders associated with obesity, the
dearth of a pragratis method to assess visceral
fat in routine examinations precludes its use as a
screening tool for the public [7-9]. Forkhead box O (FOXO) transcription factors are the main
factors that contribute the direct and indirect
pathways for glucose homeostasis. The recent
studies showed that it act
ively hyperglycemia in
chronic insulin resistance in obesity patients [10].
Developing simple and authentic methods to
assess body fat compartments should be an
important prime concern of obesity research.

1.1 Objective

Above the over weight in children is described by
using body mass index along with BMI, waist-hip
ratio, mid-upper arm circumference, waist thigh
ratio indices of body fatness is needed to
determine obesity.

The aim of the study to determine whether neck
circumference is useful alone for assessing
obesity, Children who were to 11 to 18 yrs and
undergoing schooling where the subject of the
study, trained CRRI collected the anthropometric
data from school-going children. We calculated
and correlated the neck circumference and other
indexes of obesity and we analyzed the optimal
neck circumference cutoff for identifying children
with high BMI.

2. METHODOLOGY

A cross-sectional study was conducted during the
period of August 2019- September 2019 in
the private schools, of Pondicherry. Participants
were of age 11-18 years comprising both males
and females as the separate groups. Considering
approximately 50 private schools in Puducherry ,
9 schools were chosen by systematic random
sampling method. 35 samples from each school
were selected using simple random sampling method using the lottery method with the help of attendance registry maintained in the schools to arrive at the sampling frame. A total of 280 children, among which 150 were males and 129 were females. A pretested questionnaire was used as a study stool for the data collection. The validity of the tool was assessed by consultation with expert opinion. Anthropometry measurements were taken by Doctors through proper modes.

Neck circumference was measured using a plastic tape it was measured in a standing position while the child's head was held erect with eyes looking forward, shoulders in a relaxed position, Waist circumference measurements were measured using tape. Measured at the top of the hip bone, then brought the tape and measured all the way around the body, level with the belly button. Made sure it wasn't too tight and that it's straight, even at the back. asked the children not to hold their breath while measuring, measured the number on the tape right after they exhale. Hip circumference was measured at the maximum circumference of the Gluteal region.

Participants were also examined regarding height, weight, and BMI.

**Height (cm):** Standing height was measured using an audiometer and height road. It was measured in cm; the participants were made to stand in an erect position.

**Weight (kg):** Standard weight monitoring device was used that was placed on a hard flat surface and checked for zero balance.

**BMI:** BMI was calculated by dividing weight in kg with the square of height in the meter as per the formula kg/M2.

The Data was entered in excel sheets and analysed using SPSS software version 21 [11].

### 3. RESULTS

In a total of 279 children, Table 1 shows mean anthropometric measurement values in boys. The mean weight, height, BMI, WC, HC, WHR were 71.54±9.83 kg, 161.92±7.53 cm, 27.70±1.27 kg/m², 91.07±5.29 cm, 104.28±4.63 cm, 0.87±0.07 cm respectively in obesity / above the over weight boys. Table 2 shows mean anthropometric measurement values in Girls. The mean weight, height, BMI, WC, HC, WHR were 57.54±14.77 kg, 150.87±5.6 cm, 27.72±2.12 kg/m², 87.75±4.57 cm, 97.58±4.75 cm, 0.89±0.054 cm respectively in obesity / above the over weight girls. All the anthropometric measures are significantly found to be higher in above the over weight/obesity children compare to their normal peers and higher in boys compared to girls.

The study showed that mean anthropometric measurement values in boys. The mean weight, height, BMI, WC, HC, WHR were 71.54±9.83 kg, 161.92±7.53 cm, 27.70±1.27 kg/m², 91.07±5.29 cm, 104.28±4.63 cm, 0.87±0.07 cm respectively in obesity / above the over weight boys (Table 1). The Table 2 shows mean anthropometric measurement values in girls. The mean weight, height, BMI, WC, HC, WHR were 57.54±14.77 kg, 150.87±5.6 cm, 27.72±2.12 kg/m², 87.75±4.57 cm, 97.58±4.75 cm, 0.89±0.054 cm respectively in obesity / above the over weight girls.

| Girl (mean) | Controls (normal/underweight) | Above the over weight-obesity | P-value |
|-------------|--------------------------------|-------------------------------|---------|
| Age (years) | 13.96±2.08                     | 15.16±2.08                    | 0.079   |
| Weight in kg| 42.75±9.59                     | 57.54±14.77                   | 0.005   |
| Height in cm| 152.91±8.87                    | 150.87±5.6                    | 0.275   |
| BMI (kg/m²) | 18.10±3.15                     | 27.72±2.12                    | <0.001  |
| Hip circumference in cm | 80.98±9.29 | 97.58±4.75 | <0.001 |
| Waist circumference in cm | 70±10.61 | 87.75±4.57 | <0.001 |
| Waist hip ratio | 0.85±0.075 | 0.89±0.054 | 0.028   |
| Neck circumference in cm | 29.79±2.31 | 32.85±1.927 | <0.001 |
Table 2. Pearson's correlation (r) between the neck circumference and other anthropometric measurements

|        | NC-BMI (r) | NC-WC (r) | BMI – WHR (r) | P value |
|--------|------------|-----------|---------------|---------|
| Boys   | 0.491      | 0.453     | 0.496         | <0.01   |
| Girls  | 0.708      | 0.694     | 0.300         | <0.01   |

4. DISCUSSION

The present study conducted on children aged 11-17 years had shown a notable relation between neck circumference and anthropometric measurement of obesity in both boys and girls.

Childhood obesity has become a paramount worry. Many studies had manifest expand unfavourable health issue of childhood obesity both short term besides long term consequences. Controlling the epidemic of childhood obesity, awareness prior precaution and treatment of childhood obesity are important priorities that need adequate diagnostic measures. Both patients and health practitioners must have tools with low cost, quick and easy to use for screening and monitoring [12-13].

The first person to suggest that different body morphology and type of fat distribution which is associated with health risk of obesity is Vague J. Hatipoglu et al also suggested screening circumference can be used for screening children with above the over weight and obesity and correlated positively between neck circumference and BMI, waist circumference. Nafiu et al conducted a study on 1102 children aged between 6-18 yrs had shown that neck circumference correlated with age, BMI and waist circumference in both boys and girls and neck circumference cut off value were given according to age, optimal neck circumference cutoff indicative of high BMI in boys ranged from 28.5-39 cm, in girls 327-34.6 cm respectively. Similar results were also found in other studies by Roberts et al and Mozaffer et al. The present study results which conducted on 279 students aged between 11 to 17 years has shown that neck circumference correlated with BMI, weight, hip circumference, waist circumference in both boys and girls. Optimal NC cut off values indicative of high BMI in boys ranged from 33.16-37.68 cm, in girls 30.92-34.77 cm respectively. Neck circumference is reliable and easy to measure compare to other indexies of adiposity.

5. CONCLUSION

The present study findings in children are consistent with other studies, therefore we conclude that above the over weight/obesity children could be screened through neck circumference, through which we could identify the pre obesity children and carry out the needed management since there in increased level of obesity related health conditions among the children and the adolescents.
