ABSTRACT: *Indigofera tinctoria* leaf extract has been evaluated for its anti-hepatotoxic activity on Rats. Isoniazid is a first line agent for treatment of tuberculosis. Acute ingestion by adults with little dose can lead to mild liver toxicity. In our study, administration of isoniazid (100mg/Kg of the body weight) to normal albino rats for 15 days, results in the induction of hepatitis, which is reversed by the leaf extract of *Indigofera tinctoria*. Two different dose volumes of *Indigofera tinctoria* (5ml/kg of the body weight and 10ml/kg of body weight) were given to determine the hepatoprotective efficacy. The effect of the extract was found to be dose dependent and the altered levels of AST, ALT, ALP and other serum parameters such as total protein, total bilirubin are showing normal values. *Indigofera tinctoria* provided significant protection against most of the biochemical alterations produced by isoniazid in test animals.

INTRODUCTION:

Management of liver diseases with out any side effects is still a challenge to the medical world. In the Indian system of medicine, there are several plants which are used clinically for the management of liver diseases\(^1\). One such plant is *Indigofera tinctoria* Linn. (Leguminosae papilionatae) and it is an erect, suffructicose, pubescent shrub, cultivated extensively in Northern India, especially in Bengal, Bihar, Orissa, Sind and Southern India and Madras\(^2\). *Indigofera tinctoria* is applied to the hypogastrium to promote the action of the bladder. Its leaves are recommended in various skin diseases\(^3\). It is also used in bites and strings of venomous insects and reptiles, to relieve the pain, and also to burn and scalds. Enlargement of the spleen and liver and palpitation of the heart can be minimized by *Indigofera tinctoria*\(^4\).

In allopathic medical practices, a drug known as isoniazid is used for tuberculosis therapy. Reports indicate that the patients of all ages may experience chronic or acute toxicity or side effects even at low dosage\(^5\). Our pilot study focuses on the efficacy of the *Indigofera tinctoria* Linn against isoniazid induced hepatotoxicity i.e. liver damage in rats.

MATERIALS AND METHODS

*Indigofera tinctoria* plant leaves were collected from the surrounding areas of Kattakkudi Village, Thiruvanur District, Tamilnadu. The leaves were washed and aqueous extract of *Indigofera tinctoria* was prepared. Isoniazid was purchase from general medical store within the expiry date.

Swiss albino rats of either sex weighing between 100-150g were used for this experiment. These animals were taken from the in- bred group of animals in the animal
The animals were fed with standard pellet diet supplied by Sai Durga Feeds and Foods, Bangalore. Feed and water are made available ad libitum. Studies were carried out according to the recommendations of animal ethical committee.

Rats were divided into four different groups of 10 rats each. The group receiving water (10ml/kg) was kept as control. Group II was orally administered with isoniazid (100mg/kg of body weight). Group III orally received Indigofera tinctoria leaf extract (5 ml/kg of body weight) along with isoniazid administration. Group IV rats were treated similarly like group III. But, the dose level of Indigofera tinctoria was high (10 ml/kg of body weight).

The experiment was carried out for 15 days and the blood collected at 72 hrs interval for the biochemical investigations (i.e. 3rd, 6th, 9th, 12th, 15th day of the experiment) Serum biochemical parameters such as AST, ALT, ALP, total bilirubin and protein were analysed.

AST, ALT, activities were estimate by using 2, 4-Dinitrophernyl hydrazine method. ALP activities were determined by king and Armstrong method. Total bilirubin was measured by Malloy and Evelyn method. Total protein was measured by the method of Biuret. Data were expressed as mean ± standard error and stastical analysis was carried out by using student’s t test. P values less than 0.05 were considered as significant.

RESULTS AND DISCUSSION

Biochemical parameters reflected marked changes in various enzymatic and non-enzymatic parameters of isoniazid and Indigofera tinctoria treated rats (table-1). After isoniazid administration, AST, ALT, ALP and total bilirubin levels are increased followed by a decreased serum total protein level.

The above parameters were reversed to its normal level in Indigofera tinctoria treated groups (Group III and Group IV) compared to isoniazid treated group (Group II). The high dose level to Indigofera tinctoria extract provides a considerable reduction of AST, ALT, and ALP. It may be due to the regeneration of hepatocytes and reduction of leakage of the above liver enzymes into the blood, thereby lowering its value to normal level. Herbal treatment provides considerable charges in the level of total bilirubin, when compared to isoniazid administered group. The serum protein level is an index of hepatic damage. Isoniazid treated group shows decline in protein level. After treatment with the high dose of Indigofera tinctoria extract, decline in protein level is increased to that of normal control, which may indicate the accelerated synthesis of protein in liver that shifts to normal level.

Indigofera tinctoria extract at both dose levels showed a marked hepatoprotective effect on albino rats. On the basis of change in the activity of hepatic enzymes, it seems that Indigofera tinctoria provides certain amount of protection and it corrects the liver dysfunction. However, the mechanism of action of the herb is not clear.

On the basis of experience gained during our study, we are surprised with beneficial effects of Indigofera tinctoria Linn against isoniazid. Long – term investigation should be done to know more about the effects of Indigofera tinctoria Linn against hepatotoxicity.

ACKNOWLEDGMENT.

Authors are thankful to Mr. V. Dhivakaran, Correspondent, S.T.E.T Women’s College,
Mannargudi and Dr. S. Rajasekaran, Lecture in Biochemistry, J. J, Collage of Arts and Science, Pudukkottai for their valuable co-operation and guidance.
