HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

APPLICATIONS OF THE OHSAWA-TAKEGOSHI EXTENSION THEOREM TO DIRECT IMAGE PROBLEMS

YA DENG

Abstract. In the first part of the paper, we study a Fujita-type conjecture by Popa and Schnell, and give an effective bound on the generic global generation of the direct image of the twisted pluricanonical bundle. We also point out the relation between the Seshadri constant and the optimal bound. In the second part, we give an affirmative answer to a question by Demailly-Peternell-Schneider in a more general setting. As an application, we generalize the theorems by Fujino and Gongyo on images of weak Fano manifolds to the Kawamata log terminal cases, and refine a result by Broustet and Pacienza on the rational connectedness of the image.

1. Introduction

The first goal of this paper is to study the following conjecture by Popa and Schnell on the global generation of pushforwards of pluricanonical bundles twisted by ample line bundles.

**Conjecture 1.1.** *(Popa-Schnell)* Let $f : X \to Y$ be a surjective morphism of smooth projective varieties, with $\dim(Y) = n$, and let $L$ be an ample line bundle on $Y$. Then, for every $k \geq 1$, the sheaf

$$f_* \left( K_X^k \otimes L \right)$$

is globally generated for any $l \geq k(n+1)$.

In [PS14], Popa and Schnell proved the conjecture in the case when $L$ is an ample and globally generated line bundle, and in general when $\dim(X) = 1$. In a recent preprint [Dut17], Dutta was able to remove the global generation assumption on $L$ making a statement about generic global generation with weaker bound on the twist, as in the work of Angehrn and Siu [AS95], on the effective freeness of adjoint bundles. Her theorem is as follows:

**Theorem 1.2** *(Dutta).* Let $f : X \to Y$ be a surjective morphism of projective varieties, with $Y$ smooth and $\dim(Y) = n$. Let $L$ be an ample line bundle on $Y$. Consider a klt pair $(X, \Delta)$ on $X$, with $\Delta$ $\mathbb{Q}$-effective, such that $k(K_X + \Delta)$ is a Cartier divisor for some $k \geq 1$. Denote $P = \mathcal{O}_X(k(K_X + \Delta))$. Then, for every $m \geq 1$, the sheaf

$$f_* P \otimes L^l$$

is generated by global sections at a general point $y \in Y$, either

(a) for all $l \geq k\left( \binom{n+1}{2} + 1 \right)$

or

(b) for all $l \geq k(n+1)$ when $n \leq 4$. 

*Date: October 20, 2017.*
Here \( \binom{n+1}{2} \) is the Angehrn-Siu type bound in their work on the Fujita conjecture [AS95].

Inspired by Demailly’s recent work on the Ohkawa-Takegoshi type extension theorem [Dem15] and Păun’s proof of Siu’s invariance of plurigenera [Pau07], we are able to prove the following theorem:

**Theorem A.** Let \( f : X \to Y \) be a morphism of smooth projective varieties, with \( \dim(Y) = n \), and let \( L \) be an ample line bundle on \( Y \). If \( y \) is a regular value of \( f \), then for every \( k \geq 1 \), the sheaf

\[
f_* (K_X^\otimes k) \otimes L^l
\]

is generated by global sections at \( y \) for any \( l \geq k\left(\frac{n}{\epsilon(L,y)}\right) + 1 \). Here \( \epsilon(L,y) > 0 \) is the Seshadri constant of \( L \) at the point \( y \).

Motivated in part by his study of linear series in connection with the Fujita conjecture, Demailly introduced the Seshadri constant to measure the local positivity of the ample line bundle at a point [Dem92]. After that Ein and Lazarsfeld systematically studied the Seshadri constant, and they first proved that for any ample line bundle \( L \) on a projective surface \( Y \), the Seshadri constant

\[
\epsilon(L,y) \geq 1
\]

for a very general point on \( Y \) [EL93]. Inspired by this result, they further raised the following conjecture:

**Conjecture 1.3 (Ein-Lazarsfeld).** Let \( Y \) be any projective manifold, and \( L \) any ample line bundle on \( Y \). Then the Seshadri constant

\[
\epsilon(L,y) \geq 1
\]

at a very general point \( y \in Y \).

In [EKL95], they proved the existence of universal generic bound in a fixed dimension. However, the bound is suboptimal by a factor of \( n = \dim(Y) \).

**Theorem 1.4 (Ein-Küchle-Lazarsfeld).** Let \( Y \) be a projective variety, and \( L \) an ample line bundle on \( Y \). Then for any given \( \delta > 0 \), the locus

\[
\{ y \in Y | \epsilon(L,y) > \frac{1}{n+\delta} \}
\]

contains a Zariski-dense open set in \( Y \).

Applying Theorem 1.4 to our Theorem A, we have the following general result:

**Proposition B.** With the same setting in Theorem A. For any \( k \geq 1 \), the direct image

\[
f_* (K_X^\otimes k) \otimes L^l
\]

is generated by global sections at general points of \( Y \) for any \( l \geq k(n^2 + 1) \). In particular, if the manifold \( Y \) satisfies Conjecture 1.3, then Conjecture 1.1 holds true for general points in \( Y \); that is, the direct image

\[
f_* (K_X^\otimes k) \otimes L^l
\]

is generated by global sections at general points of \( Y \) for any \( l \geq k(n+1) \).

Compared to Theorem 1.2 by Dutta, our bound for \( l \) is also quadratic on \( n \) but slightly weaker than hers. However, if we apply the result that \( K_Y + (n+1)L \) is semi-ample for any ample line bundle \( L \), we can obtain a linear bound for \( l \). Moreover, when \( K_Y \) is pseudoeffective, \( l \) can be taken independent of \( n \).

**Theorem C.** Let \( f : X \to Y \) be a surjective morphism of projective varieties, with \( X \) normal, \( Y \) smooth and \( \dim(Y) = n \). Let \( L \) be an ample line bundle over \( Y \). Consider a klt \( \mathbb{Q} \)-pair \( (X, \Delta) \) on \( X \), with \( \Delta \) effective. Then for any positive integer \( m \) such that \( m(K_X + \Delta) \) is a (integral) Cartier divisor, the direct image

\[
f_* (m(K_X + \Delta)) \otimes L^l
\]

is generated by global sections at a general point \( y \in Y \), either

(a) for all \( l \geq m(n+1) + n^2 - n \)

(b) for all \( l \geq n^2 + 2 \) when \( K_Y \) is pseudo-effective.

The second part of the paper is to study a question by Demailly-Peternell-Schneider in [DPS01]:

**Problem 1.5.** Let \( X \) and \( Y \) be normal projective \( \mathbb{Q} \)-Gorenstein varieties. Let \( f : X \to Y \) be a surjective morphism. If \(-K_X \) is pseudo-effective and its non-nef locus does not project onto \( Y \), is \(-K_Y \) pseudo-effective?

Inspired by the recent work of J. Cao on the local isotriviality on the Albanese map of projective manifolds with nef anticanonical bundles [Cao16], we give an affirmative answer to the above problem in a more general setting:

**Theorem D.** Let \( X \) be a normal projective variety and \( D \) an effective \( \mathbb{Q} \)-divisor on \( X \) such that the pair \((X, D)\) is log canonical. Let \( Y \) be a normal projective \( \mathbb{Q} \)-Gorenstein variety, and \( f : X \to Y \) is a surjective morphism.
(a) Assume that $-(K_X + D)$ is pseudo-effective, such that the non-nef locus $\NNef(-(K_X + D))$ does not project onto $Y$ via $f$. Then $-K_Y$ is pseudo-effective.

(b) If we further assume that both $X$ and $Y$ are smooth, with $\Delta$ a (not necessarily effective) $\mathbb{Q}$-divisor on $Y$, such that $-(K_X + D) - f^*\Delta$ is pseudo-effective, with its non-nef locus does not map onto $Y$. Then $-K_Y - \Delta$ is pseudo-effective with its non-nef locus contained in $(\NNef(-(K_X + D) - f^*\Delta)) \cup Z \cup Z_D$, where $Z$ is the minimal proper subvariety on $Y$ such that $f : X \setminus f^{-1}(Z) \rightarrow Y \setminus Z$ is smooth, and $Z_D$ is an at most countable union of proper subvarieties containing $Z$ such that for every $y \notin Z_D$, the pair $(f^{-1}(y), D_{f^{-1}(y)})$ is also lc.

The following theorem by Fujino and Gongyo [FG14, Theorem 1.1] is a direct consequence of our Claim (b) in Theorem D.

**Theorem 1.6** (Fujino-Gongyo). Let $f : X \rightarrow Y$ be a smooth fibration between smooth projective varieties. Let $D$ be an effective $\mathbb{Q}$-divisor on $X$ such that $(X, D)$ is lc, $\Supp(D)$ is a simple normal crossing divisor, and $\Supp(D)$ is relatively normal crossing over $Y$. Let $\Delta$ be a (not necessarily effective) $\mathbb{Q}$-divisor on $Y$. Assume that $-(K_X + D) - f^*\Delta$ is nef. Then so is $-K_Y - \Delta$.

Moreover, we can also use analytic methods to prove the following theorem.

**Theorem E.** Let $X$ be a normal projective variety and $D$ an effective $\mathbb{Q}$-divisor on $X$ such that $K_X + D$ is $\mathbb{Q}$-Cartier. Let $Y$ be a normal projective $\mathbb{Q}$-Gorenstein variety, and $f : X \rightarrow Y$ be a surjective morphism.

(a) Assume that both $X$ and $Y$ are smooth, with $(X, D)$ klt. Let $\Delta$ be a (not necessarily effective) $\mathbb{Q}$-divisor over $Y$, such that $-K_X - D - f^*\Delta$ is big and its non-nef locus $\NNef(-(K_X - D) - f^*\Delta)$ does not dominate $Y$, then $-K_Y - \Delta$ is big.

(b) Assume that the restriction of $f$ to $\NNef(-(K_X - D)) \cup \Nklt(X, D)$ does not dominate $Y$, then $-K_Y$ is big.

Here $\NNef(X, D)$ denotes the non-klt locus of $(X, D)$.

As a combination of Theorem D and E, we prove the following result, which is a generalization of another theorem by Fujino and Gongyo [FG12, Theorem 1.1].

**Corollary F.** Let $f : X \rightarrow Y$ be a smooth fibration between smooth projective manifolds. Assume that $\Delta$ is a (not necessarily effective) $\mathbb{Q}$-divisor over $Y$, $(X, D)$ is klt, and $(X_y, D_{1,X_y})$ is lc for every $y \in Y$. If $-K_X - D - f^*\Delta$ is big and nef, so is $-K_Y - \Delta$.

Finally, we apply Claim (b) in Theorem E to refine a result by Broustet and Pacienza on the rational connectedness of the image (compared to Theorem 5.6 below):

**Theorem G.** Let $X$ be a normal projective variety and $D$ an effective $\mathbb{Q}$-divisor on $X$ such that $K_X + D$ is $\mathbb{Q}$-Cartier. Let $Y$ be a normal and $\mathbb{Q}$-Gorenstein projective variety. If $f : X \rightarrow Y$ is a surjective morphism such that $-(K_X + D)$ is big and the restriction of $f$ to $\NNef(-(K_X - D)) \cup \Nklt(X, D)$ does not dominate $Y$, then $Y$ is rational connected modulo $\NNef(-(K_Y))$, that is, there exists an irreducible component $V$ of $\NNef(-(K_Y))$ such that for any general point $y$ of $Y$ there exists a rational curve $R_y$ passing through $y$ and intersecting $V$.

2. **Technical Preliminaries**

2.1. Definitions and Notations.

**Definition 2.1.** A pair consists of a normal variety $X$, together with a Weil $\mathbb{Q}$-divisor $\Delta = \sum d_i \Delta_i$ on $X$, such that the $\mathbb{Q}$-divisor $K_X + \Delta$ is $\mathbb{Q}$-Cartier on $X$.

For a pair $(X, \Delta)$ with $\Delta$ effective, the non-klt locus of is defined by

$$\Nklt(X, \Delta) := \{ x \in X | \mathcal{O}(X, \Delta)_x \neq \mathcal{O}_{X,x} \}.$$

Let us recall the definitions of non-nef locus and restrict base locus for any pseudo-effective line bundle on the normal projective variety in [BBP13, Definition 1.5]:

**Definition 2.2.** Let $X$ be a normal projective variety. Let $D$ be a pseudo-effective $\mathbb{R}$-divisor on $X$. The non-nef locus of $D$ is defined as

$$\NNef(D) := \{ c_X(v)|v(\|D\|) > 0 \},$$

where $c_X(v)$ denotes the center on $X$ of a given divisorial valuation $v$. The restricted base locus of $D$ is defined by

$$B_-(D) := \bigcup_{m \geq 0} B(D + \frac{1}{m} A),$$

where $A$ is an ample divisor, and $B(\bullet)$ denotes stable base locus of the $\mathbb{R}$-divisor.

It was proved in [BBP13, Lemma 1.6] that,

$$\NNef(D) \subset B_-(D),$$

and equality was shown to hold when $X$ is smooth.
2.2. Seshadri Constants. In the work [Dem92], Demailly define the following Seshadri constant:

**Definition 2.3.** Let $L$ be a nef line bundle over a projective algebraic manifold $X$. To every point $x \in X$, one defines the number

$$
\epsilon(L, x) := \inf \frac{L \cdot C}{\nu(C, x)}
$$

where the infimum is taken over all reduced irreducible curves $C$ passing through $x$ and $\nu(C, x)$ is the multiplicity of $C$ at $x$. $\epsilon(L, x)$ will be called the Seshadri constant $L$ at $x$.

On the other hand, Demailly also introduced another constant $\gamma(L, x)$ for any nef line bundle $L$. First, we begin with the following definition.

**Definition 2.4.** A function $\psi : X \to [0, +\infty]$ on a complex manifold $X$ of dimension $m$ is said to be quasi-plurisubharmonic (quasi-psh for short) if $\psi$ is locally the sum of a psh function and of a smooth function (or equivalently, if $\sqrt{-1}\partial\bar{\partial}\psi$ is locally bounded from below). In addition, we say that $\psi$ has neat analytic singularities if every point $x \in X$ possesses an open neighborhood $U$ on which $\psi$ can be written

$$
\psi = \epsilon \log \sum_{j=1}^{N} |g_j|^2 + w(z)
$$

where $g_j \in \mathcal{O}(U)$, $c \geq 0$ and $w(z) \in \mathcal{C}^{\infty}(U)$.

**Definition 2.5.** A singular metric $h$ on the line bundle $L$ is said to have a logarithmic pole of coefficient $\nu$ at a point $x \in X$, if on a neighborhood $U$ of $x$, the local weight $\nu$ of $h$ can be written

$$
\varphi = \nu \log \sum |z - x|^2 + w(z)
$$

where $\nu > 0$ and $w(z) \in \mathcal{C}^{\infty}(U)$. In this setting, we set $\nu(h, x) := \nu$.

Then we set

$$
\gamma(L, x) := \sup_h \nu(h, x),
$$

where the supremum is taken over all singular hermitian metrics $h$ of $L$ with positive curvature current, whose local weight $\varphi$ has neat singularities and logarithmic poles at $x$.

The numbers $\epsilon(L, x)$ and $\gamma(L, x)$ will be seen to carry a lot of useful information about the local positivity of $L$. In case $L$ is big and nef, these two constants coincide outside a certain proper subvariety of $X$ (see [Dem92, Theorem 6.4])

**Theorem 2.6** (Demailly). Let $L$ be a big and nef line bundle over $X$. Then we have

$$
\epsilon(L, x) = \gamma(L, x)
$$

for any $x \notin B_+(L)$, where $B_+(L)$ is the augmented base locus of $L$ (see [Laz04, Definition 10.2.2]). In particular, if $L$ is ample, then $\epsilon(L, x) = \gamma(L, x)$ holds everywhere.

As we mentioned in Section 1, in [EKL95], Ein, Küchle and Lazarsfeld gave the existence of universal generic bounds for the Seshadri constants in a fixed dimension.

**Theorem 2.7** (Ein-Küchle-Lazarsfeld). Let $Y$ be an irreducible projective variety of dimension $n$, and $L$ a nef line bundle on $Y$. Suppose there exists a countable union $B \subset Y$ of proper subvarieties of $Y$ plus a positive real number $\alpha > 0$ such that

$$
L^r \cdot Z \geq (\alpha \cdot r)^r
$$

for every irreducible subvariety $Z \subset Y$ of dimension $r$ ($1 \leq r \leq n$) with $Z \notin B$. Then

$$
\epsilon(L, y) \geq \alpha
$$

for all $y \in Y$ outside a countable union of proper subvarieties in $Y$. In particular, for any ample line bundle $L$ on $Y$,

$$
\epsilon(L, y) \geq \frac{1}{n}
$$

for a very general point $y$.

The above theorem gives a lower bound on the Seshadri constant of a nef and big line bundle at a very general point. However, as was also proved in [EKL96], for the ample line bundle, the above theorem is valid on a Zariski-open set by the semi-continuity of the Seshadri constant of the ample line bundle. In other word, let $L$ be an ample line bundle on an irreducible projective variety $Y$. Suppose that there is a positive rational number $B$ and a smooth point $y \in Y$ for which one knows that

$$
\epsilon(L, y) > B.
$$
Then the locus

\[ \{ z \in Y | \tau(L, z) > B \} \]

contains a Zariski-open dense set in \( Y \).

2.3. \( L^2 \) Extension Theorem. Before we state Demailly’s Ohsawa-Takegoshi type Extension Theorem, we begin with a definition in [Dem15].

**Definition 2.8.** If \( \psi \) is a quasi-psh function on a complex manifold \( X \), the multiplier ideal sheaf \( \mathcal{J}(\psi) \) is the coherent analytic subsheaf of \( \mathcal{O}_X \) defined by

\[
\mathcal{J}(\psi)_x := \{ f \in \mathcal{O}_{X,x} : \exists U \ni x, \int_U |f|^2 e^{-\psi} d\lambda < +\infty \}
\]

where \( U \) is an open coordinate neighborhood of \( x \), and \( d\lambda \) the standard Lebesgue measure in the corresponding open chart of \( \mathbb{C}^n \). We say that the singularities of \( \psi \) are log canonical along the zero variety \( Y := V(\mathcal{J}(\psi)) \) if \( \mathcal{J}((1 - \epsilon)\psi)|_Y = \mathcal{O}_{X|_Y} \) for every \( \epsilon > 0 \).

If \( \psi \) possesses both neat and log canonical singularities, it is easy to show that the zero scheme \( V(\mathcal{J}(Y)) \) is a reduced variety. In this case one can also associate in a natural way a measure \( d\tilde{V}_Y,\omega[\psi] \) on the set \( Y^\circ := Y^{\text{reg}} \) of regular points of \( Y \) as follows. If \( g \in \mathcal{C}_c(Y^\circ) \) is a compactly supported continuous function on \( Y^\circ \), and \( \tilde{g} \) compactly supported extension of \( g \) to \( X \), we set

\[ (2.3) \int_{Y^\circ} g d\tilde{V}_Y,\omega[\psi] := \limsup_{t \to +\infty} \int_{x \in X, t < \psi(x) < t + 1} \tilde{g}(x) dV_X,\omega. \]

Here \( \omega \) is a Kähler metric on \( X \), and \( dV_X,\omega = \frac{\omega^n}{n!} \). In [Dem15] Demailly proved that the limit does not depend on the continuous extension \( \tilde{g} \), and one gets in this way a measure with smooth positive density with respect to the Lebesgue measure, at least on an (analytic) Zariski open set in \( Y^\circ \).

We are ready to recall the Ohsawa-Takegoshi type extension Theorem by Demailly. We only need a special case of his very general statement:

**Theorem 2.9** (Demailly). Let \( X \) be a smooth projective manifold, and \( \omega \) a Kähler metric on \( X \). Let \( L \) be a holomorphic line bundle equipped with a (singular) hermitian metric \( h \) on \( X \), and let \( \psi : X \to \mathbb{R} \to -\infty, +\infty \) be a quasi-psh function on \( X \) with neat analytic singularities. Let \( Y \) be the analytic subvariety of \( X \) defined by \( Y = V(\mathcal{J}(Y)) \) and assume that \( \psi \) has log canonical singularities along \( Y \), so that \( Y \) is reduced. Finally, assume that the curvature current

\[ i\Theta_{L,h} + \alpha \sqrt{-1} \nabla \overline{\nabla} \psi \geq 0 \]

for all \( \alpha \in [1, 1 + \delta] \) and some \( \delta > 0 \). Then for every section \( s \in H^0(Y^\circ, (K_X \otimes L)|_{Y^\circ}) \) on \( Y^\circ := Y^{\text{reg}} \) such that

\[ \int_{Y^\circ} |s|_{\omega,h}^2 dV_{Y^\circ,\omega}[\psi] < +\infty, \]

there is an extension of \( S \in H^0(X, K_X \otimes L) \) whose restriction to \( Y^\circ \) is equal to \( s \), such that

\[ \int_X \gamma(\delta s)|S|_{\omega,h}^2 e^{-\psi} dV_X,\omega \leq \frac{34}{\delta} \int_{Y^\circ} |s|_{\omega,h}^2 dV_{Y^\circ,\omega}[\psi]. \]

Here we set

\[ \gamma = \begin{cases} 
\frac{e^{-\frac{x}{2}}}{1 + x^2} & \text{if } x \geq 0, \\
1 & \text{if } x < 0.
\end{cases} \]

A direct consequence of Theorem 2.9 is the following extension theorem for fibrations:

**Corollary 2.10.** Let \( f : X \to Y \) be a surjective morphism between smooth manifolds. For any ample line bundle \( L \) on \( Y \), any regular value \( y \) of \( f \), if the Seshadri constant of \( L \) satisfies

\[ (2.4) \epsilon(L, y) > \dim(Y) = n, \]

then for any pseudo-effective line bundle \( L_1 \) over \( X \) with a singular hermitian metric \( h \) such that \( \Theta_{L_1,h} \geq 0 \), and the restriction of \( h \) to \( X_y \) is not identically zero, any section \( s \) of

\[ H^0(X_y, (K_X \otimes f^*L \otimes L_1)|_{X_y} \otimes f(h|_{X_y})). \]

can always be extended to a global one

\[ S \in H^0(X, K_X \otimes f^*L \otimes L_1) \]

with certain \( L^2 \) estimates which do not depend on \( L_1 \).
Proof. Since $L$ is ample over $Y$, one can find a smooth hermitian metric $h_0$ on $L$ with the curvature form $i\Theta_{L,h_0} \geq \omega$, where $\omega$ is some Kähler form on $Y$.

By the lower bound of Seshadri constant $\epsilon(L,y) \geq n$, we can find a global quasi-psh function $\varphi$ with neat singularities on $Y$ such that
(a) $i\Theta_{L,h_0} + \sqrt{-1} \partial \bar{\partial} \varphi \geq 0$;
(b) $\varphi$ is smooth outside $y$;
(c) on a neighborhood $W$ of $y$, we have
$$\varphi = (1 + \delta)n \log \sum |z - y|^2 + w(z)$$
where $\delta > 0$ and $w(z) \in \mathcal{C}^{\infty}(W)$ with $w(y) = 0$

Now set $\psi := \frac{1}{1+\delta} \varphi \circ f$, which is a quasi-psh function with neat singularities on $X$. Moreover, since $y$ is the regular value of $f$, the inverse image $X_y := f^{-1}\{y\}$ is a finite disjoint union of closed smooth submanifolds of codimension $n$ in $X$, and the multiplier ideal sheaf
$$\mathcal{I}(\psi) = \mathcal{I}(\mathcal{I}^{(n)}_{X_y}) = \mathcal{I}_{X_y}.$$ 
Here $\mathcal{I}^{(n)}_{X_y}$ is the ideal sheaf consisting of germs of functions that have multiplicity $\geq n$ at a general point of $X_y$: $\mathcal{I}^{(n)}_{X_y} : = \{ f \in \mathcal{O}_X | \operatorname{ord}_x(f) \geq n \text{ for a general point } x \in X \}.$

Thus $\mathcal{I}(\psi)$ has log canonical singularities, and we have
$$i\Theta_{L,h} + i\Theta_{f^*L,f^*h_0} + \alpha \sqrt{-1} \partial \bar{\partial} \psi \geq 0$$
for all $\alpha \in [1, 1+\delta]$. Then for any section $s$ of
$$H^0(X_y, (K_X \otimes f^*L \otimes L_1)_1|_{X_y} \otimes \mathcal{I}(h_1|_{X_y})), $$
we can apply Theorem 2.9 to extend $s$ to a global section $S \in H^0(X, K_X \otimes f^*L \otimes L_1 \otimes \mathcal{I}(h))$
such that
$$\int_X \gamma(\delta \psi) |s|^2_{\omega,f^*h_0|h_1} e^{-\psi} dV_{X,\omega} \leq \frac{34}{\delta} \int_{X_y} |s|^2_{\omega,f^*h_0|h_1} dV_{X_y,\omega} \{\psi\}.$$ 
Assume that $\dim(X) = m \times n$. From (2.3) one can then check that $dV_{X_y,\omega} \{\psi\}$ is the smooth measure supported on $X_y$, such that
$$dV_{X_y,\omega} \{\psi\} = C_0 \frac{\omega^m_{\mathcal{I}_{X_y}}}{m!},$$
where $C_0$ is some constant depending only on $m, n$. Since $\delta$ depends only on $\epsilon(L,y)$, write $C := \frac{34}{\delta} C_0$ which does not depend on $L_1$. We thus obtain
$$\int_X \gamma(\delta \psi) |s|^2_{\omega,f^*h_0|h_1} e^{-\psi} dV_{X,\omega} \leq C_0 \int_{X_y} |s|^2_{\omega,f^*h_0|h_1} \frac{\omega^m_{\mathcal{I}_{X_y}}}{m!},$$
where the $L^2$ estimate does not depend on $L_1$. \hfill\Box

2.4. The Extension Theorem for Twisted Pluricanonical Bundles. We recall the following twisted pluricanonical extension theorem, which was inspired by that used by J. Cao to prove the local triviality of Albanese maps of projective manifolds with nef anticanonical bundles [Cao16]. It is a consequence of [BP10, Section A.2].

Theorem 2.11. Let $Y$ be a $n$-dimensional projective manifold and let $A_Y$ be any line bundle on $Y$ such that the difference $A_Y - K_Y$ is an ample line bundle. Let $f : X \to Y$ be a surjective morphism from a smooth projective manifold $X$ to $Y$ and $L$ be a pseudo-effective line bundle on $X$ with a possible singular metric $h_L$ such that
$$i\Theta_{h_L}(L) \geq 0.$$ 
Assume that there exists some regular value $z$ of $f$, we have
(i) all the sections of the bundle $mK_X + L$ extend near $z$,
(ii) $H^0(X_z, (mK_X + L_1|_{X_z}) \otimes \mathcal{I}(h_{L_1|_{X_z}})) \neq \emptyset$.
Then for any $y \in Y$ such that
(a) $y$ is the regular value of $f$,
(b) the Seshadri constant $\epsilon(A_Y - K_Y, y) > n$,
(c) all the sections of the bundle $(mK_X + L_1|_{X_y})$ extend locally near $y$,
the restriction map
$$H^0(X, mK_X/Y + L + f^*A_Y) \to H^0(X_y, (mK_X + L_1|_{X_y}) \otimes \mathcal{I}(h_{L_1|_{X_y}}))$$
is surjective. In particular, the choice of $A_Y$ depends only on $Y$ and is independent of $f, L, m$. 

Proof. Thanks to [BP10, A.2.1], the conditions (i) and (ii) imply that there exists a $m$-relative Bergman type metric $h_{m,B}$ on $mK_{X/Y} + L$ with respect to $h_L$ such that $i\Theta h_{m,B}(mK_{X/Y} + L) \geq 0$. Thus $h := h_{m,B} \cdot h_L^{\frac{1}{m}}$ defines a possible singular metric on

$$\bar{L} := \frac{m-1}{m}(mK_{X/Y} + L) + \frac{1}{m}L = (m-1)K_{X/Y} + L,$$

with $i\Theta h(\bar{L}) \geq 0$.

Take any $s \in H^0(X_y, (mK_{X_y} + L_{1\upharpoonright X_y}) \otimes \mathcal{I}(h_{L_{1\upharpoonright X_y}}^{\frac{1}{m}}))$. It follows from Condition (a), (b) and (c), and the construction of the $m$-relative Bergman kernel metric that $|s|^2_{h_{m,B}}$ is $C^0$-bounded. Then we see that

$$\int_{X_y} |s|^2_{\omega, h^{\frac{1}{m}}} dV_{\omega, \omega} = \int_{X_y} |s|^2_{h_{m,B}} |s|^2_{\omega, h_L^{\frac{1}{m}}} dV_{\omega, \omega} \leq C \int_{X_y} |s|^2_{\omega, h_L^{\frac{1}{m}}} dV_{\omega, \omega} < +\infty.$$

We then can apply Corollary 2.10 to $K_X + \bar{L} + f^*(A_Y - K_Y)$, to extend $s$ to a section in $H^0(X, K_{X/Y} + \bar{L} + f^*A_Y)$. In conclusion, the restriction

$$H^0(X, mK_{X/Y} + L + f^*A_Y) \rightarrow H^0(X_y, (mK_{X_y} + L_{1\upharpoonright X_y}) \otimes \mathcal{I}(h_{L_{1\upharpoonright X_y}}^{\frac{1}{m}}))$$

is surjective and the theorem is proved. \hfill $\square$

One can see that there exists a non-empty Zariski open set of $Y^\circ \subset Y$ such that for any $y \in Y^\circ$, it satisfies Condition (a), (b) and (c) in Theorem 2.11.

3. On the Conjecture of Popa and Schnell

Let $f : X \rightarrow Y$ be the surjective morphism between smooth projective manifolds, and let $L$ be an ample line bundle on $Y$ with a smooth hermitian metric $h_0$ such that the curvature form $i\Theta h_0 \geq \omega$ for some Kähler metric $\omega$ on $Y$. Assume that $\dim(Y) = n$ and $\dim(X) = m + n$. Fix any point $y$ on $Y$ which is the regular value of $f$. Take any positive real number $\nu$ such that

$$\epsilon(L, y) > \frac{1}{\nu}.$$

Then we have

$$\epsilon([n\nu]L, y) > n.$$

Set $\tilde{L} := [n\nu]L$ with the smooth hermitian metric $\tilde{h} := f^*h_0^{\frac{n\nu}{L}}$, then we can restate Corollary 2.10 in the following variant form:

Proposition 3.1. There is a globally defined quasi-psh function $\psi_0$ defined over $X$ and a positive number $\delta$ such that, for any pseudo-effective line bundle $L_1$ equipped with the possible singular hermitian metric $h_1$, whose curvature current $i\Theta L_1, h_1 \geq 0$ and $h_1$ is not identically zero when restricted on $X_y$, for any section

$$s \in H^0(X_y, (K_X \otimes \tilde{L} \otimes L_1)_{1\upharpoonright X_y} \otimes \mathcal{I}(h_{1_{1\upharpoonright X_y}})),$$

there is a global section

$$S \in H^0(X, K_X \otimes \tilde{L} \otimes L_1)$$

whose restriction to $X_y$ is $s$, such that

$$\int_{X_y} \gamma(\delta \psi_0)|S|^2_{\omega, \tilde{h}_1} e^{-\psi_0} dV_{\omega, \omega} \leq C \int_{X_y} |s|^2_{\omega, h_1} dV_{\omega, \omega}.$$ 

Here $dV_{\omega, \omega} := \frac{\omega^{m\upharpoonright X_y}}{m!}$, and $C$ is some constant which does not depend on $L_1$.

Thus from Proposition 3.1, if we set $L_1$ to be the trivial bundle on $X$, we see that the following morphism

$$H^0(X, K_X \otimes f^*L^{[n\nu]} \rightarrow H^0(X_y, (K_X \otimes f^*L^{[n\nu]})_{1\upharpoonright X_y})$$

is always surjective. As one can take $\nu$ to be arbitrary close to $\frac{1}{\epsilon(L, y)}$ so that $[n\nu] = \left\lfloor \frac{n}{\epsilon(L, y)} \right\rfloor + 1$, we see that the direct image $f_*K_X \otimes L^{[n\nu][1/\epsilon(L,y)]}$ is generated by global sections at $y$. Since $y$ is an arbitrary regular value of $f$, we thus prove Theorem A for $k = 1$. In order to prove the theorem for any $k \geq 2$, we need to apply the techniques in proving Siu’s invariance of plurigenera [Siu97] by Păun [Pau07].
Proof of Theorem A. Fix any \( k \geq 2 \) and any \( \sigma \in H^0(X, k(K_X + \hat{L})) \). We want to find a global section
\[
\Sigma \in H^0(X, k(K_X + \hat{L}))
\]
whose restriction to \( X_p \) is \( \sigma \).

Choose a very ample line bundle \( A \) on \( X \) such that for every \( r = 0, \ldots, k - 1 \), the line bundle \( F_{0,r} := r(K_X + \hat{L}) + A \) is globally generated by sections
\[
\{ u_j^{(0,r)} \}_{j=1, \ldots, N_r} \subset H^0(X, F_{0,r}).
\]
We then define inductively a sequence of line bundles
\[
F_{q,r} := (qk + r)(K_X + \hat{L}) + A
\]
for any \( q \geq 0 \), and \( 0 \leq r \leq k - 1 \). By constructions we have
\[
\begin{align*}
F_{q,r+1} & = K_X + F_{q,r} + \hat{L} \quad \text{if } r < k - 1, \\
F_{q+1,0} & = K_X + F_{q,k-1} + \hat{L} \quad \text{if } r = k - 1.
\end{align*}
\]
We are going to construct inductively families of sections, say \( \{ u_j^{(q,r)} \}_{j=1, \ldots, N_r} \) of \( F_{q,r} \) over \( X \), together with ad hoc \( L^2 \) estimates, such that each \( u_j^{(q,r)} \) is an extension of \( v_j^{(q,r)} \), where we set
\[
v_j^{(q,r)} := \sigma^q u_j^{(0,r)} \in H^0(X, F_{q,r}).
\]

Now, by induction, assume that such \( \{ u_j^{(q,r)} \}_{j=1, \ldots, N_r} \) above can be constructed. Then \( F_{p,r} \) can be equipped with a natural singular hermitian metric \( h_{q,r} \) defined by
\[
|\xi|^2_{h_{q,r}} := \frac{|\xi|^2}{\sum_{j=1}^{N_r} |u_j^{(q,r)}|^2},
\]
such that \( i\Theta_{h_{q,r}} \geq 0 \). Let \( h_{K_X} \) be the smooth hermitian metric of the canonical bundle \( K_X \) induced by the volume form \( dV_{X,\omega} \), and set \( \hat{h} := h_{K_X} \hat{h} \) to be the smooth metric on \( K_X + \hat{L} \), then by construction the pointwise norm with respect to the metric \( h_{q,r} \) is
\[
\begin{align*}
|v_j^{(q,r+1)}|_{h_{q,r},\hat{h}}^2 &= \frac{|v_j^{(0,r+1)}|_{h_{q,r},\hat{h}}^2}{\sum_{i=1}^{N_r} |u_i^{(0,r)}|_{h_{q,r},\hat{h}}^2} \quad \text{if } r < k - 1, \\
|v_j^{(q+1,0)}|_{h_{q,r},\hat{h}}^2 &= \frac{|\sigma^q v_j^{(0,0)}|_{h_{q,r},\hat{h}}^2}{\sum_{j=1}^{N_r} |v_j^{(0,0)}|_{h_{q,r},\hat{h}}^2} \quad \text{if } r = k - 1.
\end{align*}
\]
where \( h_A \) is a smooth hermitian metric on \( A \) with strictly positive curvature. Since the sections \( \{ u_j^{(0,r)} \}_{j=1, \ldots, N_r} \) generates \( F_{0,r} \), there is a constant \( C_1 > 0 \) such that \( (3.2) \) is uniformly \( C^0 \) bounded above by \( C_1 \). From \((3.1)\), it then follows from Proposition 3.1 that one can extend \( v_j^{(q,r+1)} \) (or \( v_j^{(q+1,0)} \) if \( r = k - 1 \)) to a section \( u_j^{(q,r+1)} \) (\( u_j^{(q+1,0)} \) respectively) over \( X \) such that
\[
\begin{align*}
\int_X \gamma(\delta\psi_0) e^{-\psi_0} \sum_{j=1}^{N_{r+1}} |u_j^{(q,r+1)}|^2_{h_{q,r},\hat{h}} dV_{X,\omega} \leq C_2 & \quad \text{if } r < k - 1, \\
\int_X \gamma(\delta\psi_0) e^{-\psi_0} \sum_{j=1}^{N_0} |u_j^{(q+1,0)}|^2_{h_{q,r},\hat{h}} dV_{X,\omega} \leq C_2 & \quad \text{if } r = k - 1.
\end{align*}
\]
for some uniform constant \( C_2 \). From \((3.2)\), \((3.3)\) is equivalent to
\[
\begin{align*}
\int_X \gamma(\delta\psi_0) e^{-\psi_0} \sum_{i=1}^{N_{r+1}} |u_i^{(q,r+1)}|^2_{h_{q,k+r+1}h_A} dV_{X,\omega} \leq C_2 & \quad \text{if } r < k - 1, \\
\int_X \gamma(\delta\psi_0) e^{-\psi_0} \sum_{i=1}^{N_0} |u_i^{(q+1,0)}|^2_{h_{q,k}h_A} dV_{X,\omega} \leq C_2 & \quad \text{if } r = k - 1.
\end{align*}
\]
Let us denote by
\[
a_{q+k+r}(x) := \sum_{i=1}^{N_r} |u_i^{(q,r)}|_{h_{q+k+r}h_A},
\]
which is a quasi-psh and bounded non-negative smooth function on $X$. By the integrability of $\log \gamma(\delta \psi_0)$ and $\psi_0$ with respect to the standard Lebesgue measure over $X$, combined with the concavity property of the logarithmic function as well as the Jensen inequality, we can find some constant $C_3$ and $C_4$ such that

\[
(3.5) \quad \int_X \log \frac{a_l}{a_{l-1}} dV_{X,\omega} \leq C_3 - \int_X \log \gamma(\delta \psi_0) dV_{X,\omega} + \int_X \psi_0 dV_{X,\omega} \leq C_4
\]

for any $l \geq 1$. Since $a_1(x)$ is a bounded smooth function on $X$, we can also find a constant $C_5 \geq C_4$ such that

\[
\int_X \log a_1 dV_{X,\omega} \leq C_5.
\]

Combined these inequalities together we obtain

\[
\int_X \frac{\log a_l}{l} dV_{X,\omega} \leq C_5
\]

for any $l \geq 1$. Set $f_q := \frac{\log a_q}{q}$, and we have the following properties:

(a) for any $q \geq 1$, we have

\[
\int_X f_q dV_{X,\omega} \leq C_5;
\]

(b) the inequality

\[
k\Theta_h^\omega(KX + \hat{L}) + \sqrt{-1} \partial \bar{\partial} f_q \geq - \frac{1}{q} \Theta_h(A)
\]

holds true in the sense of currents on $X$;

(c) on $X_y$ the following equality is satisfied

\[
f_{q!} X_y = \int_X \log |\sigma|_{h^k} + a_0(x)\cdot x_y
\]

where $a_0(x) = \log \sum_{i=1}^{N_0} |u_i^{(0,0)}|_{hA}$ is a smooth function on $X$.

By the mean value inequality for the psh functions, as a consequence of the properties (a) and (b), one can show the existence of a uniform upper bound for the functions $f_q$ over $X$. Thus the sequence $f_q(z)$ must have some subsequence which converges in $L^1$ topology on $X$ to the potential $f_\infty$, in the form of the regularized limit

\[
f_\infty(z) := \limsup_{\zeta \to z} \lim_{q \to +\infty} f_{q!}(\zeta),
\]

which satisfies

\[
k\Theta_h^\omega(KX + \hat{L}) + \sqrt{-1} \partial \bar{\partial} f_\infty \geq 0
\]

as a current on $X$. Moreover, by Property (c) $f_\infty$ is not identically $-\infty$ on $X_y$, as well as

\[
f_\infty \geq \log |\sigma|_{h^k} + c(1)
\]

pointwise on $X_y$.

Now we construct a singular hermitian metric $h_\infty$ on $(k-1)(KX + L)$ defined by

\[
h_\infty := \hat{h}^{k-1} e^{-\frac{1}{k-1} f_\infty}.
\]

Then $\Theta_{h_\infty}((k-1)(KX + \hat{L})) \geq 0$. Write $k(KX + L) = KX + (k-1)(KX + \hat{L}) + \hat{L}$, where $(k-1)(KX + \hat{L})$ is equipped with the singular hermitian metric $h_\infty$. Since

\[
|\sigma|^2_{\omega, h_\infty} = |\sigma|^2_{h_\infty} = |\sigma|_{h_\infty}^{2(k-1)} \cdot |\sigma|^2_{\hat{h}}
\]

which is $\mathcal{E}^0$ bounded, we then can apply Proposition 3.1 to extend $\sigma$ to a global section $\Sigma \in H^0(X, k(KX + \hat{L}))$.

In conclusion, for any regular value $y$ of the morphism $f$, the following morphism

\[
H^0(X, K_X^{\otimes k} \otimes f^* L^{\otimes l}) \to H^0(X_y, (K_X^{\otimes k} \otimes f^* L^{\otimes l})|_{X_y})
\]

is always surjective for any $l > \frac{p}{\epsilon(L_Y)}$. Thus Theorem A is proved. \qed

In order to improve the above quadratic bound to linear, we need to apply the twisted pluricanonical extension theorem in Section 2.4 instead. First, we recall the following result arising from birational geometry:

**Theorem 3.2.** Let $L$ be an ample line bundle over a projective $n$-fold $Y$, then the adjoint line bundle $K_Y + (n+1)L$ is semi-ample.

Based on the Mori theory, one observes that $n+1$ is the maximal length of extremal rays of smooth projective $n$-folds, which shows that $K_Y + (n+1)L$ is nef. By the base-point-free theorem, one can even show that $K_Y + (n+1)L$ is semiample. In his work on the Fujita conjecture [Dem96], Demailly also gave an analytic proof for the fact that $K_Y + (n+1)L$ is nef.
Proof. (Proof of Theorem C) Take a a log resolution $\mu: X' \to X$ of $(X, \Delta)$ such that

$$K_{X'} = \mu^*(K_X + \Delta) + \sum_i a_i E_i - \sum_j b_j F_j,$$

where $a_i, b_j \in \mathbb{Q}_+$, and $\sum_i E_i + F_j$ is a divisor with simple normal crossing support. By the assumption that $(X, \Delta)$ is klt and $\Delta$ is effective, each $E_i$ is an exceptional divisor and $0 < b_j < 1$ for each $b_j$. Denote $f' := f \circ \mu$. Then $f': X' \to Y$ is a surjective morphism between smooth projective manifolds.

It follows from Theorem 3.2 that $K_Y + (n + 1)L$ can be equipped with a smooth hermitian metric $h_1$ with semi-positive curvature. If we further assume that $K_Y$ is pseudo-effective, $(m - 1)K_Y + L$ is big for any $m \geq 1$ and thus can be equipped with a singular hermitian metric $h$ with mild singularities such that $\Theta_h \geq \epsilon \omega$ for some hermitian form $\omega$ over $Y$. Observe that if $m(K_X + \Delta)$ is a (integral) Cartier divisor, then $ma_i, mb_j \in \mathbb{Z}^+$ for each $a_i, b_j$. Let us equip the divisor $\sum_j mb_j F_j$ with the canonical singular hermitian metric $h_2$ so that $\sqrt{-1}\Theta_{h_2} = \sum_j mb_j [F_j]$. For any point $y \in Y$, denote by $X'_y$ the fiber of $f': X' \to Y$. Let us denote $P := (m - 1)f^*(K_Y + (n + 1)L) + \sum_j mb_j F_j$ equipped with the (semi-positive curved) singular hermitian metric $h_P := f^* h_1^{m-1} \cdot h_2$ in the general setting; and when $K_Y$ is pseudo-effective, denote $P := f^*((m - 1)K_Y + L) + \sum_j mb_j F_j$ with the (semi-positive curved) singular hermitian metric $h_P := f^* h \cdot h_2$.

Recall that $\sum_j F_j$ is simple normal crossing and $0 < b_j < 1$. Then for general $y \in Y$, $\mathcal{J}(h_P^{1/2}_{X_y}) = \mathcal{O}_{X'_y}$. By Theorem 2.7, when $k \geq n^2 + 1$, the Seshadri constant

$$\epsilon(kL, y) > n$$

for a general $y \in Y$. So we can apply Theorem 2.11 to show that, the restriction map

$$H^0\left(X', mK_{X'/Y} + P + f^*(K_Y + L)\right) \to H^0\left(X'_y, (mK_{X'} + \sum_j mb_j F_j)_{|X'_y}\right)$$

is surjective for a generic $y$ in $Y$. In other word,

$$H^0\left(X', \mu^*(mK_X + m\Delta + lf^*L) + \sum_i ma_i E_i\right) \to H^0\left(X'_y, m(\mu^*(K_X + \Delta) + \sum_i a_i E_i)_{|X'_y}\right)$$

is surjective for a generic $y$ in $Y$ for any $l \geq m(n + 1) + n^2 - n$ in the general cases, and for $l \geq n^2 + 2$ when $K_Y$ is pseudo-effective.

Since each $E_i$ is an exceptional divisor of the birational morphism $\mu: X' \to X$, the natural inclusion

$$H^0\left(X', \mu^*(mK_X + m\Delta + lf^*L)\right) \to H^0\left(X', \mu^*(mK_X + m\Delta + lf^*L) + \sum_i ma_i E_i\right)$$

is thus an isomorphism. Thus one also has the surjectivity

$$H^0\left(X', \mu^*(mK_X + m\Delta + lf^*L)\right) \to H^0\left(X'_y, m(\mu^*(K_X + \Delta))_{|X'_y}\right).$$

In other words, the direct image

$$f^*_L(\mu^*(mK_X + m\Delta + lf^*L)) = f_*(mK_X + m\Delta) \otimes \mathcal{L}^{l}$$

generated by global sections at the generic points of $Y$ when $l \geq m(n + 1) + n^2 - n$, and for $l \geq n^2 + 2$ when $K_Y$ is pseudo-effective. This completes the proof of Theorem C. \qed

Remark 3.3. In a recent very interesting preprint [LPS17], Lombardi, Popa and Schnell proved that, when $Y$ is an Abelian variety, the sheaves $f_*(mK_X)$ become globally generated after pullback by an isogeny. Their result is surprising since the extension does not require any local positivity. Since they use deep tools like GV sheaves, it is tempting to ask whether one can use analytic methods to give another proof of their results.

4. On a Question of Demailly-Peternell-Schneider

In this section, we prove Theorem D and thus give an affirmative answer to Problem 1.5 in the case that both $X$ and $Y$ are smooth manifolds.

Proof of Theorem D. Take a sufficiently divisible $q \in \mathbb{N}$ such that both $q\Delta$ and $qD$ are Cartier divisors, and a sufficient ample line bundle $A_X$ on $X$ such that $A_X + qD$ is ample a smooth hermitian metric $h$ on $A_X + qD$ such that $i\Theta_h \geq 3\omega$ for some Kähler metric $\omega$, and the direct image $f_*(A_X)$ is a torsion free coherent sheaf which is not only locally free but also globally generated over the Zariski open set $X' := X \setminus f^{-1}(Z)$. Then $f_*(A_X)$ is locally free outside a subvariety $W \subset Z$ of codimension at least 2. Set $r$ to be the generic rank of $f_*(A_X)$, and denote by

$$\det f_*(A_X) := \Lambda^rf_*(A_X)^{**}$$

to be the bidual of $\Lambda^r f_*(A_X)$ which is an invertible sheaf over $Y$, then there is coherent ideal sheaf $\mathcal{I}$ supported on $W$ such that

$$\Lambda^rf_*(A_X) = \det f_*(A_X) \otimes \mathcal{I}.$$
Let us also choose a very ample line bundle $A_Y$ on $Y$ such that $A_Y - K_Y$ generates $n + 1$ jets everywhere and $A_Y + \det \phi(A_X)$ is also an ample line bundle on $Y$. In particular, the Seshadri constant $\epsilon(A_Y - K_Y, y) > n$ for any $y$.

It follows from Definition 2.2 that, for any $\mathbb{R}$-divisor $E$, the restricted base locus of $E$ is defined by

$$
B_-(E) = \bigcup_{m > 0} B(E + \frac{1}{m}A)
$$

where $A$ is an ample divisor, and the definition being independent of $A$. Equivalently, in [BDPP13], it is shown that

$$
B_-(E) = \bigcup_{m \in \mathbb{N}} \bigcap_{T \in c_1(E)[-\frac{1}{m}\omega]} E_+(T),
$$

where $T$ runs over the set $c_1(E)[-\frac{1}{m}\omega]$ of all closed real $(1, 1)$-currents $T \in c_1(E)$ such that $T \geq -\frac{1}{m}\omega$, and $E_+(T)$ denotes the locus where the Lelong numbers of $T$ are strictly positive. By [Bou02], there is always a current $T_{\min, m}$ which achieves minimum singularities and minimum Lelong numbers among all members of $c_1(E)[-\frac{1}{m}\omega]$, hence

$$
B_-(E) = \bigcup_{m \in \mathbb{N}} E_+(T_{\min, m}).
$$

By Demailly’s regularization theorem in [Dem92b], for every $m \in \mathbb{N}$, we can find a closed $(1, 1)$-current $T_m \in c_1(E)$ with neat singularities such that $T_m \geq -\frac{2}{m}\omega$, and

$$
E_+(T_{\min, 2m}) \subset E_+(T_m) \subset E_+(T_{\min, m}).
$$

Therefore, when $E$ is a Cartier divisor, there exists a singular hermitian metric $\tilde{h}_m$ on $E$ with neat singularities, such that the curvature current

$$
i\Theta_{\tilde{h}_m} = T_m \geq -\frac{2}{m}\omega.
$$

Set $E := -q(K_X + D) - f^*(q\Delta)$. Since $B_- \left( -q(K_X + D) - f^*(q\Delta) \right) = B_- \left( -(K_X + D) - f^*(\Delta) \right)$ does not project onto $Y$, thus for any $m \in \mathbb{N}$, $Z_m := f(E_+(T_m))$ is a proper subvariety of $Y$, and the singular hermitian metric $\tilde{h}_m^{\otimes m} h$ on $-mq(K_X + D) - mqf^*\Delta + A_X + qD$ is smooth on $X \setminus f^{-1}(Z_m)$.

For the $\mathbb{Q}$-effective divisor $D = \sum_{i=1}^I a_i D_i$, there is a canonical singular hermitian metric $h_D$ defined on $qD$, with the local weight

$$
\varphi_D = \sum_{i=1}^I qa_i \log |g_i|,
$$

where $g_i \in \Gamma(U, \mathcal{O}_U)$ is a holomorphic function locally defining $D_i$ on some open set $U \subset X$. Therefore, the curvature current

$$
i\Theta_{h_D} = [qD] \geq 0,
$$

and thus $h_D$ is a singular hermitian metric with neat singularities.

Recall that $Z_D$ is denoted to be the minimal set containing $Z$, such that for every $y \notin Z_D$, the pair $(X_y, D|_{X_y})$ is also lc. Here we denote by $X_y := f^{-1}(y)$. Since $(X, D)$ is lc, thus $Z_D$ is an at most countable union of proper subvarieties of $Y$. Indeed, the set

$$
Y_m := \{ y \notin Z((X_y, (1 - \frac{1}{m})D|_{X_y}) \text{ is klt} \}
$$

is a Zariski open set of $Y$. Therefore, one has

$$
Z_D = \bigcup_{m=1}^{\infty} Y \setminus Y_m.
$$

Thus for the singular hermitian metric $h_m := \tilde{h}_m^{\otimes m} h_D^{\otimes m-1}$ on $-mqK_X + A_X - mqf^*\Delta$, the multiplier ideal sheaf

$$
\mathcal{J}(h_m^{\otimes m}|_{X_y}) = \mathcal{J}((1 - \frac{1}{m})D|_{X_y}) = \mathcal{O}_{X_y}
$$

for any $y \in Y_m \setminus Z_m$. Moreover, the curvature current $i\Theta_{h_m} \geq \omega$.

Denote $L := -mqK_X + A_X - mf^*(\Delta)$. For any $y \in Y_m \setminus Z_m$, all the sections of the bundle $(mqK_X + L)|_{X_y} = (A_X - mf^*(\Delta))|_{X_y}$ extend locally near $y$, and thus it satisfies Condition (a), (b) and (c) in Theorem 2.11. It then follows from (4.1) and Theorem 2.11 that the restriction

$$
H^0(X, mqK_X|_Y - mqK_X + A_X - mqf^*\Delta + f^*A_Y) \rightarrow H^0(X_y, A_X|_{X_y})
$$

is surjective for any $y \in Y_m \setminus Z_m$. In other words, the direct image sheaf

$$
f_* \left( mqK_X|_Y - mqK_X + A_X - mqf^*\Delta + f^*A_Y \right) = (-K_Y - \Delta)^{\otimes mq} \otimes A_Y \otimes f_*(A_X)
$$
is generated by global sections over $Y_m \setminus Z_m$, and by the assumption that $f_\ast(A_X)$ is locally free over $Y \setminus Z$, we conclude that the top exterior power

$$\Lambda^r((K_Y - \Delta) \otimes A_Y \otimes f_\ast(A_X)) = (-K_Y - \Delta) \otimes A_Y \otimes \det f_\ast(A_X)$$

is also generated by global sections over $Y_m \setminus Z_m$. In particular, for every $m \in \mathbb{N}$, the base locus

$$(4.3) \quad \text{Bs}((K_Y - \Delta) \otimes A_Y \otimes \det f_\ast(A_X)) \subset Z_m \cup Y \setminus Y_m.$$

By our choice of $A_Y$, $rA_Y + \det f_\ast(A_X)$ is an ample line bundle on $Y$, thus let $m$ tends to infinity, we obtain the pseudo-effectivity of $-K_Y - \Delta$. Moreover, it follows from (4.3) that the restricted base locus

$$\mathbf{B}_-(K_Y - \Delta) \subseteq \bigcup_{m=1}^\infty Z_m \cup Y \setminus Y_m = f(\mathbf{B}_-(K_X - D - f^\ast \Delta)) \cup Z_D.$$

Hence Claim (b) is proved.

Let us prove Claim (a). Let $p : Y' \to Y$ be a log-resolution of singularities of $Y$. Let $\mu : X' \to X$ be a log resolution of $(X, D)$, such that the induced rational map $f' : X' \to Y'$ is in fact a morphism. We have the following commutative diagram:

$$
\begin{array}{ccc}
X' & \xrightarrow{\mu} & X \\
\downarrow{f'} & & \downarrow{f} \\
Y' & \xrightarrow{p} & Y.
\end{array}
$$

Moreover, $K_{X'} + D' = \mu^\ast(K_X + D) + F$, where $D'$ and $F$ are both effective $\mathbb{Q}$-divisors without common components. Moreover, $D'$ is log canonical and $F$ is exceptional. For any $q \in \mathbb{N}$ such that $q(K_X + D)$ is a Cartier divisor, both $qF$ and $qD'$ are also Cartier. By [BBP13, Lemma 2.6], we also have

$$\mu(\text{NNef}(-\pi^\ast(K_X + D))) \subset \text{NNef}(-(K_X + D)).$$

Thus by the assumption of the theorem, we have

$$(4.4) \quad f'(\text{NNef}(-(K_{X'} - D' + F)) \subseteq Y'.$$

Repeat the proof of Claim (b) with $K_X + D$ replaced by $K_X' + D' - F$, one can prove that, after one fixes certain ample divisors $A_X$ and $A_Y$ over $X'$ and $Y'$, for any $m \in \mathbb{N}$, the restriction

$$H^0(X', mqK_{X'/Y'} - mqK_{X'} + mqF + A_{X'} + f^\ast A_{Y'}) \to H^0(X_{y'}, (mqF + A_{X'})_{x_{y'}})$$

is surjective for a general point $y$ in $Y$. Since $F$ is an effective exceptional divisor, the natural inclusion

$$H^0(X', mqK_{X'/Y'} - mqK_{X'} + A_{X'} + f^\ast A_{Y'}) \to H^0(X', mqK_{X'/Y'} - mqK_{X'} + mqF + A_{X'} + f^\ast A_{Y'})$$

is an isomorphism, and thus the restriction

$$H^0(X', mqK_{X'/Y'} - mqK_{X'} + A_{X'} + f^\ast A_{Y'}) \to H^0(X_{y'}, A_{X_{x_{y'}}})$$

is surjective for a general point $y$ in $Y'$. By the same proof as above, we conclude that $-K_{Y'}$ is pseudo-effective, and it follows from Lemma 4.1 below that $-K_Y$ is also pseudo-effective. We finish the proof of Claim (a). \hfill \square

**Lemma 4.1.** Let $\mu : Y' \to Y$ be a birational morphism from the smooth projective variety $Y'$ to the normal $\mathbb{Q}$-Gorenstein variety $Y$. When $-K_{Y'}$ (resp. $K_{Y'}$) is pseudo-effective, so is $-K_Y$ (resp. $K_Y$).

**Proof.** For any sufficiently large $m \in \mathbb{N}$ such that $mK_Y$ is Cartier, there exists effective exceptional divisors $E$ and $F$ on $Y'$ such that

$$\mu^\ast(-mK_Y) = -mK_{Y'} + E - F.$$

Take an ample divisor $A$ over $Y'$ such that, for some effective exceptional divisors $G, \mu^\ast A - G$ is also ample over $Y'$. When $-K_{Y'}$ is pseudo-effective, $-mK_{Y'} + \mu^\ast(A) - G$ is big, and thus for a sufficiently large $l \in \mathbb{N}$, there exists a non-zero section

$$s \in H^0(Y', \mu^\ast(A - mK_Y) - IG + lF - lE).$$

The non-zero section $s \cdot IG \cdot lE \in H^0(Y', \mu^\ast(A - mK_Y) + lF)$ gives rise to a section $s' \in H^0(Y, lA - lmK_Y)$.

Since $m$ can be chosen arbitrarily large, we conclude that $-K_Y$ is pseudo-effective. The same proof also holds when $K_{Y'}$ is pseudo-effective. \hfill \square

If $f$ is a smooth fibration, $\text{Supp}(D)$ is a simple normal crossing divisor, and $\text{Supp}(D)$ is relatively normal crossing over $Y$, then the condition that $(X, D)$ is lc implies that $(X_y, D_{x_y})$ is also lc for every $y \in Y$. Thus $Z_D = \emptyset$. If $-K_X - D - f^\ast \Delta$ is nef, then $\mathbf{B}_-(K_X - D - f^\ast \Delta) = \emptyset$. Thus from Theorem 1.6, $\mathbf{B}_-(K_Y - \Delta)$ is also empty which implies that $-K_Y - \Delta$ is nef. This completes our proof of Theorem 1.6.

By setting $D = 0$ and $\Delta = 0$ in Theorem 1.6, the following theorem by Miyaoka is a direct consequence.

**Theorem 4.2 (Miyaoka).** Let $f : X \to Y$ be a smooth morphism between smooth projective manifolds $X$ and $Y$. If $-K_X$ is nef, then so is $-K_Y$. 
Remark 4.3. The original proof of Miyaoka [Miy93] relies on the mod $p$ reduction arguments. There is also another Hodge theoretic proof by Fujino and Gongyo without using the mod $p$ reduction arguments [FG14].

Remark 4.4. In [CZ13], M. Chen and Q. Zhang proved the similar result as Claim (a) in Theorem D, under the stronger assumption that $-(K_X + D)$ is nef. In a very recent preprint [Ou17], W. Ou extended the theorem by Chen-Zhang to the rational dominant maps, which was a crucial step in his proof of the generic nefness conjecture for tangent sheaves by T. Peternell [Pet12, Conjecture 1.5].

5. ON THE INHERITANCE OF THE IMAGE

5.1. On the Images of Weak KLT Fano Manifolds. One says that a projective manifold $X$ is weak Fano if $-K_X$ is big and nef. In the series of articles [FG12] and [FG14], Fujino and Gongyo studied the image of weak Fano manifolds. They proved the following theorem:

Theorem 5.1 (Fujino-Gongyo). Let $f : X \to Y$ be a smooth fibration between two smooth manifolds $X$ and $Y$. If $X$ is weak Fano, then so is $Y$.

In this section, we will prove Claim (a) in Theorem E:

Proof of Claim (a) in Theorem E. Take a very ample line bundle $A_Y$ over $Y$ such that $A_Y$ generates $n + 1$ jets everywhere. Since $-K_X - D - f^* \Delta$ is big, we can find a a sufficiently divisible $a \in \mathbb{N}$ such that $-a(K_X + D + f^* \Delta) - 2f^* A_Y$ is an effective line bundle. Fix any effective divisor $E \in |-a(K_X + D + f^* \Delta) - 2f^* A_Y|$. Since $(X, D)$ is klt, then there exists a sufficiently divisible integer $m > a$ such that the multiplier ideal sheaves

$$\mathcal{J}(\frac{1}{m - 1}E|_{X_y}) = \mathcal{J}(\frac{m}{m - 1}D|_{X_y}) = \mathcal{O}_{X_y}$$

(5.1)

for the generic fiber $X_y$, and both $mD$ and $m\Delta$ are Z-divisors. We can also find a singular hermitian metric $h_1$ with neat singularities on $-(m^2 - a)(K_X + D + f^* \Delta)$ such that $i\Theta_{h_1} \geq \omega$ for some Kähler metric $\omega$ on $X$. Take some small rational number $\epsilon > 0$ such that $\mathcal{J}(h_1^{1-\epsilon}_{X_y}) = \mathcal{O}_{X_y}$ for the generic fiber $X_y$.

On the other hand, since the non-nef locus $\text{NNef}(-K_X - D - f^* \Delta)$ does not project onto $Y$, it follows from the proof of Theorem D in Section 4 that, one can find a singular hermitian metric $h_0$ over $-(m^2 - a)(K_X + D + f^* \Delta)$ with neat singularities, such that $i\Theta_{h_0} \geq -c\omega$ and the singularities of $h_0$ does not project onto $Y$. Set $h := h_1^{1-\epsilon}$ which is also a hermitian metric on $-(m^2 - a)(K_X + D + f^* \Delta)$, then we have $i\Theta_h \geq c\omega$ and the multiplier ideal sheaf

$$\mathcal{J}(h_{1|X_y}) = \mathcal{O}_{X_y}$$

(5.2)

for the generic fiber $X_y$.

Take a generic fiber $X_y$ of $f$ such that $y$ is the regular value of $f$, and both (5.1) and (5.2) are satisfied. We equip the line bundle $-m^2(K_X + D + f^* \Delta) - 2f^* A_Y + m^2 D$ with the singular hermitian metric $h_0 := h_0 \cdot h_0^{m^2}$, where $h_0$ (resp. $h_D$) is the tautological singular hermitian metric on $-a(K_X + D + f^* \Delta) - 2f^* A_Y$ (resp. $D$) induced by the effective divisor $E$ (resp. $D$), such that

$$i\Theta_{h_D} = [E] \quad (\text{resp. } i\Theta_{h_D} = [D]).$$

Then we claim that the multiplier ideal sheaf $\mathcal{J}(h_0^{1|X_y}) = \mathcal{O}_{X_y}$. Indeed, for any $s \in \mathcal{O}_{X_y, z}$, let $\varphi_E, \varphi_D$ and $\varphi$ be the weights of the metric $h_E, h_D$ and $h$ on a small neighborhood $U \subset X_y$ of a point $z \in X_y$. Then by the Hölder inequality we have

$$\left( \int_U |s|^2 e^{-\frac{\varphi_E}{m^2} + \varphi_D} \right)^{\frac{1}{2}} \leq \left( \int_U |s|^2 e^{-\frac{\varphi}{m^2}} \right)^{\frac{m-1}{m}} \cdot \left( \int_U |s|^2 e^{-\frac{\varphi_D}{m}} \right)^{\frac{1}{m}} < +\infty.$$

Here we use the conditions (5.1) and (5.2). By applying Theorem 2.11 with $L = -(m^2(K_X + f^* \Delta) - 2f^* A_Y$ endowed with the singular hermitian metric $h_0$, for general $y \in Y$, we obtain the desired surjectivity:

$$H^0(X, m^2 K_X \cap Y) + (-m^2 K_X - m^2 f^* \Delta - 2f^* A_Y \cap f^* A_Y) \to H^0(X_y, f^*(-m^2 K_Y - m^2 \Delta - A_Y)|_{X_y}) = \mathbb{C}^l,$$

where $l$ is the number of the connected components of $X_y$. In particular, we have the non-vanishing

$$H^0(X, f^*(-m^2 K_Y - m^2 \Delta - A_Y)) \neq 0.$$

Now we claim that $-m^2 K_Y - m^2 \Delta - A_Y$ is a pseudo-effective line bundle over $Y$. Indeed, we first take a Stein factorization of $f$

$$X \xrightarrow{f} Y \xrightarrow{\pi} Y',$$

where $p : Y' \to Y$ is a finite surjective morphism and the morphism $f' : X \to Y'$ has connected fibers. Then we have an isomorphism

$$f^* : H^0(X, f^*(-m^2 K_Y - m^2 \Delta - A_Y)) \cong H^0(Y', p^*(-m^2 K_Y - m^2 \Delta - A_Y)),$$

which implies that the line bundle $p^*(-m^2 K_Y - m^2 \Delta - A_Y)$ is effective. Since $p : Y' \to Y$ is a finite surjective morphism, by a result of S. Boucksom [Bou02, Proposition 4.2], $-m^2 K_Y - m^2 \Delta - A_Y$ is a pseudo-effective line bundle, which also shows that $-K_Y - \Delta$ is big.
Therefore, we can extend Theorem 5.1 to the weak klt Fano cases:

**Proof of Theorem F.** Since $f$ is a smooth fibration, $(X, D)$ is klt, and $(X_y, D_{|X_y})$ is also klt for every $y \in Y$, from the very definition of $Z_D$ in Theorem D we see that $Z_D = \emptyset$. By the nefness of $-(K_X + D) - f^*\Delta$, the set

$$\mathbb{B}_-(-(K_X + D) - f^*\Delta) = \emptyset.$$ 

Thus from Theorem D we conclude that $-K_Y - \Delta$ is nef. The bigness of $-K_Y - \Delta$ follows from Theorem F directly. This completes the proof. 

By setting $D = 0$ and $\Delta = 0$ in Theorem F, we obtain Theorem 5.1 directly.

**Remark 5.2.** If we only assume that $-K_X$ is big, then the following example given in [FG12] shows that, even if $f$ is smooth, $-K_Y$ is not big.

**Example 5.3.** Let $E \subset \mathbb{P}^2$ be a smooth cubic curve. Consider $f : X = \mathbb{P}^1(\mathcal{O}_E \oplus \mathcal{O}_E(1)) \to E = Y$. Then, we see that $-K_X$ is big. However, $-K_Y$ is not big since $E$ is a smooth elliptic curve.

It is noticeable that, in [Pan12] S. Boucksom pointed out that the following theorem, which is a special case of Theorem 1.2 in [Ber09], implies [FG12, Theorem 4.1] or [KMM92, Corollary 2.9]:

**Theorem 5.4** (Boucksom-Păun). Let $f : X \to Y$ be a smooth fibration between two smooth manifolds. If $-K_X$ is semi-positive (strictly positive), then $-K_Y$ is semi-positive (strictly positive).

Finally, let us mention that, in [FG12], the authors raised the following conjecture, which was solved very recently by C. Birkar and Y. Chen [BC16]:

**Theorem 5.5** (Fujino-Gongyo, Birkar-Chen). Let $f : X \to Y$ be a smooth fibration between two smooth projective manifolds. If $-K_X$ is semi-ample, then so is $-K_Y$.

The proof in [BC16] relies on very deep consequences of the minimal model program in birational geometry and of Hodge theory. It is an interesting question to know whether we can use pure analytic methods to give a new proof of this theorem.

### 5.2. On the Rational Connectedness of the Image.

By Mori’s bend-and-break, Fano varieties are uniruled; in fact by [Cam92, KMM92] a stronger result holds: the projective Fano variety is rationally connected. Later on Q. Zhang and Hacon-McKernan proved that the same conclusion holds for a klt pair $(X, D)$ such that $-(K_X + D)$ is big and nef [Zha06, HM07]. This was generalized by Broustet and Pacienza [BrP11, Theorem 1.2], who proved that a klt pair $(X, D)$ with $-(K_X + D)$ big is rationally connected modulo the non-nef locus of $-(K_X + D)$, that is, there exists an irreducible component $V$ of $\mathbb{B}_-(-(K_X + D))$ such that for any general point $x$ of $X$ there exists a rational curve $R_x$ passing through $X$ and intersecting $V$. Moreover, they also proved the following result for the image:

**Theorem 5.6** (Broustet-Pacienza). Let $(X, D)$ be a pair such that $-(K_X + D)$ is big. Let $f : X \to Y$ be a dominant rational map with connected fibers such that the restriction of $f$ to $\text{Nef}(-(K_X + D)) \cup \text{Klt}(X, D)$ does not dominate $Y$, then $Y$ is uniruled.

In this subsection, we will refine their results in a more general setting. First, we need to prove Claim (b) in Theorem E:

**Proof of Claim (b) in Theorem E.** Let $p : Y' \to Y$ be a log-resolution of singularities of $Y$. Let $\pi : X' \to X$ be a log resolution of $(X, D)$, such that the induced rational map $f' : X' \to Y'$ is in fact a morphism. We have the following commutative diagram:

$$\begin{array}{ccc}
X' & \xrightarrow{\pi} & X \\
\downarrow{\pi} & & \downarrow{f} \\
Y' & \xrightarrow{p} & Y.
\end{array}$$

Let $D'$ be an effective $\mathbb{Q}$-divisor on $X'$ such that $\pi_*(D') = D$ and $K_{X'} + D' = \pi^*(K_X + D) + F$, with $F$ effective and not having common components with $D'$. Note that

$$\pi(\text{Klt}(X', D')) \subset \text{Klt}(X, D).$$

By [BBP13, Lemma 2.6], we also have

$$\pi\left(\text{Nef}\left(-\pi^*(K_X + D)\right)\right) \subset \text{Nef}\left(-(K_X + D)\right).$$

It then follows from the assumption of the theorem that

$$f'(\text{Nef}(\pi^*(K_{X'} + D') + F) \cup \text{Klt}(X', D')) \not\subset Y'$$

(5.3)
Take a very ample line bundle $A_{Y'}$ over $Y'$ such that $A_{Y'} - K_{Y'}$ generates $n + 1$ jets everywhere. We can take an ample line $A_{Y'} := p^*A_Y - E_Y$ over $Y'$, where $E_Y = \sum c_i E_i$’s are exceptional divisors of $p$. Since $-K_{X'} - D'$ is big, so is $-K_{X'} - D' + F$, and we can find a sufficiently divisible $a$ such that $-a(K_{X'} + D' - F) - 2f^*A_{Y'}$ is an effective line bundle. Fix any effective divisor $E \in |-a(K_{X'} + D' - F) - 2f^*A_{Y'}|$. By (5.3), for any sufficiently divisible $m > a$, the multiplier ideal sheaf

$$\mathcal{J}(\frac{1}{m-1}E_{1|X'_y}) = \mathcal{J}(\frac{m}{m-1}D'_{1|X'_y}) = \mathcal{O}_{X'_y}$$

for the generic (smooth) fiber $X'_y$ of $f' : X' \rightarrow Y'$. We can also find a singular hermitian metric $h_1$ with neat singularities on $-(m^2 - a)(-K_{X'} - D' + F)$ such that $i\Theta_{h_1} \geq \omega$ for some Kähler metric $\omega$ on $X'$. Take some small rational number $\epsilon > 0$ such that $\mathcal{J}(h_{1|X'_y}) = \mathcal{O}_{X'_y}$ for the generic fiber $X'_y$.

On the other hand, it follows from (5.3) that the non-nef locus $\text{Nef}(-K_{X'} - D' + F)$ does not project onto $Y'$, and from the proof of Theorem D in Section 4, one can find a singular hermitian metric $h_0$ over $-(m^2 - a)(K_{X'} + D' - F)$ with neat singularities, such that $i\Theta_{h_0} \geq -\epsilon \omega$ and the singularities of $h_0$ does not project onto $Y$. Set $h := h_1^{2\epsilon}h_0^{-\epsilon}$ which is also a hermitian metric on $-(m^2 - a)(K_{X'} + D' - F)$, then we have $i\Theta_h \geq 2\epsilon \omega$ and the multiplier ideal sheaf

$$\mathcal{J}(h_{1|X'_y}) = \mathcal{O}_{X'_y}$$

for the generic fiber $X'_y$.

Take a generic regular value $y \in Y'$ of $f'$ such that the fiber $X'_y$ is reduced and smooth, and both (5.4) and (5.5) are satisfied. We equip the line bundle $-m^2(K_{X'} + D' - F) - 2f^*A_Y + m^2D'$ with the singular hermitian metric $h_0 := h_E h_{1|Y'}$, where $h_E$ (resp. $h_{1|Y'}$) is the tautological singular hermitian metric on $-a(K_{X'} + D' - F) - 2f^*A_{Y'}$ (resp. $m^2D'$) induced by the effective divisor $E$ (resp. $m^2D'$), such that

$$i\Theta_{h_E} = [E](\text{ resp. } i\Theta_{h_{1|Y'}} = m^2[D'])$$

Then we claim that the multiplier ideal sheaf $\mathcal{J}(h_{1|Y'_y}) = \mathcal{O}_{X'_y}$. Indeed, for any $s \in \mathcal{O}_{X'_y}$, let $\varphi_E, \varphi_{1|Y'}$ and $\varphi$ be the weights of the metric $h_E$, $h_{1|Y'}$ and $h$ on a small neighborhood $U \subset X'_y$ of a point $z \in X'_y$. Then by the Hölder inequality we have

$$\int_U |s|^2 e^{-\frac{\varphi_E + \varphi_{1|Y'} + \varphi}{m-1}} \leq \left( \int_U |s|^2 e^{-\varphi_E} \right) \frac{m-1}{m} \cdot \left( \int_U |s|^2 e^{-\varphi_{1|Y'}} \right) \frac{m-1}{m} \cdot \left( \int_U |s|^2 e^{-\frac{\varphi}{m(m-1)^2D'}} \right) \frac{m-1}{m} < +\infty.$$
Proof of Theorem G. The proof is more or less direct. By Claim (b) in Theorem E we see that \(-K_Y\) is big. By Broustet-Pacienza’s Theorem [BrP11, Theorem 1.2], \(Y\) is rationally connected modulo the non-nef locus \(\text{Nef}(-K_Y)\). The theorem is thus proved.

Acknowledgements. The first version of this work was finished during my PhD studies. I would like to warmly thank my former advisor Professor J.-P. Demailly for his numerous suggestions on this work, and also for his constant encouragements and supports. I thank Professors Sébastien Boucksom, Gianluca Pacienza and Mihnea Popa for the discussions and improvements they suggested. I also thank Junyan Cao for his interests and kindly sharing his ideas to me, Chen Jiang for the fruitful discussions and improvements he suggested, and Yajunasi Dutta for the patient explanations of her work. The work is supported by ERC ALKAGE project and the postdoctoral project funded by Labex IRMIA.
