Abstract

Background: Tissue inhibitor of metalloproteinase-2 (TIMP2), an endogenous inhibitor of matrix metalloproteinases, has been disclosed to participate in the development and carcinogenesis of multiple malignancies. However, the prognosis of TIMP2 in different cancers and its correlation with tumor microenvironment and immunity have not been clarified.

Methods: In this study, we conducted a comprehensive bioinformatics analysis to evaluate the prognostic and therapeutic value of TIMP2 in cancer patients by utilizing a series of databases, including ONCOMINE, GEPIA, cBioPortal, GeneMANIA, Metascape, and Sangerbox online tool. The expression of TIMP2 in different cancers were analyzed by Oncomine, TCGA and GTEx databases and mutation status of TIMP2 in cancers was then verified using cBioportal database. The protein-protein interaction (PPI) network of the TIMP family was exhibited by GeneMANIA. The prognosis of TIMP2 in cancers was performed though GEPIA database and cox regression. Additionally, the correlations between TIMP2 expression and immunity (immune cells, gene markers of immune cells, TMB, MSI, and neoantigen) were explored using Sangerbox online tool.

Results: The transcriptional level of TIMP2 in most cancerous tissues were significantly elevated. Survival analysis revealed that elevated expression of TIMP2 was associated with unfavorable survival outcome in multiple cancers. Enrichment analysis demonstrated the possible mechanisms of TIMPs and their associated genes mainly involved in pathways including extracellular matrix (ECM) regulators, degradation of ECM and ECM disassembly, and several other signaling pathways.

Conclusions: Our findings systematically dissected that TIMP2 was a potential prognostic maker in various cancers and use the inhibitor of TIMP2 may be an effective strategy for cancer therapy to improve the poor cancer survival and prognostic accuracy, but concrete mechanisms need to be validated by subsequent experiments.

Introduction

Cancer, a vicious disease, is the second leading cause of death globally the statistics are daunting [1]. Given the situation, the requirement for biomarker-matched molecularly targeted treatment for cancers shows the trend of increasingly recognized. The investigation of novel and promising biomarkers as cancer mediators and therapeutic targets has now spanned multiple decades. In order to pinpoint novel biomarkers and develop new interventions, we firstly and comprehensively delineated the expression spectrums and prognostic value of tissue inhibitor of metalloproteinases 2 (TIMP2) in diverse malignancies, which triggered fundamental cellular responses and was a vital player during tumorigenesis.

TIMP2, ascribed to TIMP family members, functioned as an endogenous inhibitor of matrix metalloproteinases (MMPs) and a homeostatic regulator at the interface between extracellular matrix (ECM) and cellular components [2, 3]. TIMP2, located on chromosome 17q25, has been indicated in the
modulation of MMP-2 proteolytic activity via formation of a 1:1 stoichiometric suppressive complex with the enzyme [4, 5]. Tumor environment (TME) was coincident with increasing levels of active MMPs expression, which was overwhelmed by TIMP2, resulting in tumor promoting functions [2]. TIMP2 has been shown to exhibit multiple interactions with components of the ECM by targeting several putative receptors, such as membrane-bound MMP146 [6, 7], integrin α3β15 [6] and insulin-like growth factor 1 receptor (IGFR1) [3]. These implicated that TIMP2 was involved in multiple different cancer-promoting processes, aiding discoveries in identifying therapeutic targets regarding the TIMP-metalloproteinase-substrate network.

Clinical cancer bioinformatics was emphasized as a crucial tool and emerging science, which might serve as a new paradigm for guiding cancer research. Recently, escalating online platforms for the mining, sharing, analysis and integration of cancer data have came into existence. In this study, we had a sophisticated understanding of TIMP2 in pan-cancer on basis of data-mining analysis from various databases, providing a theoretical basis for cancer diagnosis and prognosis.

Materials And Methods

Oncomine database

Oncomine (http://www.oncomine.org) is a free and public cancer microarray data for academic research community [8]. Relative mRNA expression of TIMP2 in various cancer tissues compared with the normal tissues is analyzed by Oncomine. The thresholds are defined at p-value$\leq 1E^{-4}$, fold change$\geq 2$, gene rank top 10%.

cBioPortal database

The cBioCancer Genomics Portal (cBioPortal database, http://cbioportal.org) is a newly developed interactive, open-access web server for the exploration of numerous cancer genomics datasets, based on the data retrieved from the TCGA database [9]. Analysis of the genomic alterations of TIMP2 included copy number amplification, deep deletion, missense mutation with uncharted significance and mRNA upregulation. 32 studies (10967 samples) in Pancancer studies module were selected.

GEPIA database

GEPIA (Gene Expression Profiling Interactive Analysis) database (http://gepia.cancer-pku.cn/index.html) is an open-access web resource for analyzing the RNA sequencing expression data from the TCGA and the Genotype-Tissue Expression (GTEx) database, and provides customizable functions including differential expression analysis, correlation analysis and survival analysis [10]. In current study, we mainly used the GEPIA database to get the overall survival (OS) and DFS data of TIMP2 of high level of TIMP2 patients and low levels of TIMP2 patients.

GeneMANIA database
The GeneMANIA (https://www.genemania.org/) was adopted to predict the potential functions of TIMP2. GeneMANIA produced a series of genes with similar functions to TIMP2 and exhibited a gene-gene interaction network to expound relationships between TIMP2 and its associated genes. In this study, we constructed this interactive functional-association network for TIMP2 in terms of genetic interactions, co-expression, co-localization, physical interactions, predictions and protein domain similarity [11].

**Relationship between TIMP2 expression and immunity**

Cancer progression is an intricate process controlled by a series of factors that coordinate the crosstalk between immune components of TME and the tumor cells. Knowledge of the sophisticated interplay between tumor and immunity could aid in formulating novel combination treatments to conquer tumor immune evasion mechanisms and direct immunotherapy decision-making. Attuned with these facts, we explored the relationship between the level of TIMP2 expression and immunity by using Sangerbox online tool, including infiltrating immune cells, gene markers of immune cells, tumor mutational burden (TMB), microsatellite instability (MSI), and neoantigen.

**Functional and pathway enrichment analysis**

Functional and pathway enrichment analysis of TIMP family members and co-expressed genes were next performed using Metascape. Metascape website (http://metascape.org) is a friendly and well-maintained gene-list analysis online tool for gene analysis and annotation, which integrated analysis tools and biological information to offer a systematic annotation [12]. The Molecular Complex Detection (MCODE) algorithm was employed to screen the densely connected modules of PPI network. Gene Ontology (GO) terms for biological process, cellular component, and molecular function categories were enriched based on the Metascape online tool.

**Statistical analysis**

The expression data from Oncomine database is analyzed by Student's t-test. Transcripts per million (TPM) serves as a measurement of the proportion of transcripts in the pool of RNA. The expression level of TIMP2 is showed with log2 TPM. The prognostic values of high- and low-expression groups were evaluated according to the hazard ratio (HR), 95% confidence interval (CI), and log-rank P-values. P-value<0.05 indicated statistically significant differences.

**Results**

**The expression and mutation Profiling of TIMP2 in different cancer types**

Cancer is a disease of the genome and develops as one end-product of accumulating somatic mutation [13, 14]. Remarkable advances in next-generation sequencer (NGS) and computational technology dealing with massive data make it available to synthetically analyze cancer genome profiles at clinical and research levels [14]. Thus, our aim was to explore genomic mutation profiling of TIMP2 in pan-cancer, regarding analysis of TIMP2 was exhibited by cBioPortal database. The genetic alteration
characterization of TIMP2 showed that its amplification was one of the most important single factors for alteration in liver cancer, BRCA, mesothelioma, sarcoma, lung adenocarcinoma, LGG, CRC, uveal melanoma, PCPG, esophagus cancer, pancreas cancer, thyroid cancer, GBM and ccRCC. Besides, TIMP2 mutation frequencies are the highest in liver cancer, BRCA and mesothelioma (Figure. 1A). The Oncomine database showed that TIMP2 mRNA levels were significantly upregulated in nine cancer datasets, especially lymphoma (15 reported). Meanwhile, leukemia was the most down-expression cancer type (9 reported). Additionally, we visualized the expression of TIMP2 genes in various cancer tissues and adjacent tissues in Figure 1C, the higher TPM levels of TIMP2 in multiple cancers were observed (P < 0.05). Data extracted from TCGA database revealed that TIMP2 expression was notably higher in 10 tumor types compared to matched TCGA normal tissues and GTEx data, including CHOL, GBM, HNSC, KIRP, LAML, LGG, LIHC, PAAD, SKCM, STAD (Figure 1C).

The prognostic significance of TIMP2 expression in different cancer types

Kaplan Meier curves displayed elevated expression of TIMP2 was an unfavorable prognostic factor for cancer patients, including overall survival (OS, Figure 2A) and disease-free survival prognosis (DFS, Figure 2B). As shown in Figure 2C, high mRNA expression of TIMP2 predicted worse survival for UCEC (HR = 1.3, 95%CI: 1.08-1.55, P = 0.0046), BLCA (HR = 1.15, 95%CI: 1.05-1.25, P = 0.0019), MESO (HR = 1.59, 95%CI: 1.13-2.24, P = 0.0082), STAD (HR = 1.25, 95%CI: 1.07-1.45, P = 0.0037) LGG (HR = 1.39, 95%CI: 1.05-1.85, P = 0.022), and KICH (HR = 2.16, 95%CI: 1.12-4.17, P = 0.022) respectively.

The correlation between TIMP2 expression and immune infiltrates

When analyzing the association between TIMP2 expression and immune sub-types, it was found that the expression of TIMP2 was most positively associated with central memory CD4+ T cell, central memory CD8+ T cell, effector memory CD4+ T cell, effector memory CD8+ T cell, gamma delta T cell, immature dendritic cell, mast cell, MDSC, memory B cell, natural killer cell, natural killer T cell, plasmacytoid dendritic cell, regulatory T cell, T follicular helper cell and type 1 T helper cell. Furthermore, TIMP2 was most positively associated with major immune cells in OV, LUAD, LUSC, PARD, BLCA, ESCA, PAAD, LIHC, BRCA, COAD, STAD, THCA, READ and LGG (Figure. 3A). With regards to gene markers of immune cells, the expression of TIMP2 was found to positively correlate with CD276. PRAD, COAD, THCA and KICH were top four tumors which had the most gene markers of immune cells positively associated with TIMP2 expression (Figure. 3B). Analysis of the relationship between TIMP2 expression and six common immune cells revealed that the expression of TIMP2 positively correlated with COAD, LIHC, PRAD, LUAD, OV, ACC, LGG, READ and THCA (Figure. 3C). In addition, our study found that TIMP2 expression were positively correlated with ImmuneScore, StromalScore, and ESTIMATEScore in THCA, HNSC, LAML, READ, LGG, DLBC, KICH, OV, LUAD, LUSC, PRAD, BLCA, ESCA, TGCT and PAAD (Figure. 3D). These results suggested that TIMP2 expression might be involved in regulating the aforementioned immune molecules and play a vital role in immune microenvironment.

Relationship between TIMP2 expression and TMB, MSI, and neoantigen
TMB is defined as the number of somatic mutations detected on next generation sequencing (NGS) per megabase (mb) [15, 16]. As measured by immunohistochemistry, high TMB is an emerging biomarker of predicting the response to immune checkpoint inhibitors [17]. Across tumor diagnoses, patients with high TMB might be an optimal subgroup for ICI therapy and have a higher likelihood of immunotherapy [16, 18]. More broadly, neoantigens arise from tumor-specific mutations that differ from wild-type antigens, which is a major factor in the activity of clinical immunotherapies and may guide application of immunotherapies [19] [20]. These observations indicated that TMB, MSI, and neoantigen might form biomarkers in the immune response to cancer patients and provide the progress of novel therapeutic approaches with an incentive. In addition, TIMP2 was positively correlated with TMB in OV, LGG and SKCM, and negatively correlated with TMB in STAD and KIRP (Figure. 4A). TIMP2 was positively correlated with MSI in UVM and TGCT, and negatively correlated with MSI in HNSC, STAD and UCEC (Figure. 4B). TIMP2 was negatively correlated with neoantigen in with MSI in STAD (Figure. 4C).

**Functional Annotation of Co-expression Gene Network of TIMP2**

The TIMP family (TIMP-1, 2, 3, 4), a class of transcription factors, has four members, are roughly 40% identical in amino acid sequence, and TIMP2 and TIMP4 share most similarities [21]. As shown in Figure 5A, 20 genes showed the greatest association with TIMPs in the gene interaction network, including RECK, MMP1, MMP14, MMP3, MMP2, AGTR2, PCSK5, ESR1, ADAM17, MMP9, MXRA8, EFEMP1, MMP8, ETV4, JUND, EGR1, ADAMTS4, ADAM15, STAT3 and JUNB. Further functional analysis revealed that the top six pathways related to these genes were M3468: NABA ECM REGULATORS (logP=-22.8947, z-score=30.68476), M167: PID AP1 PATHWAY (logP= -19.2461, z-score= 37.29148), R-HSA-6785807: Interleukin-4 and Interleukin-13 signaling (logP=-19.1111, z-score= 31.49618), GO:0051045: negative regulation of membrane protein ectodomain proteolysis (logP=-17.967, z-score=47.44123), GO:1901652: response to peptide (logP=-15.867, z-score=16.87997), and GO:0001568: blood vessel development . (Figure. 5C) Moreover, it was also related to the metabolism of insulin, glucose, and fat, and cell surface receptor signaling pathways which regulate immune response. The top 3 most relevant MCODE modules were NABA ECM regulators, degradation of the extracellular matrix and extracellular matrix disassembly (Figure. 5D).

**Discussion**

TIMPs firmly participated in the development and process of the majority of cancer hallmarks, and may serve as promising biomarkers for cancer prognosis in patient body fluids [21]. Tissue inhibitors of metalloproteinases (TIMPs) are proteins approximately 21 kDa in molecular weight and consisting of 184–194 amino acids [21, 22]. They are dimers composed of an N-terminal domain and a smaller C-terminal domain binding to the MMPs substrate [23]. Thus, the family of TIMPs (TIMP-1, 2, 3, 4) are able to mediate the degradation of MMPs and prominently appreciated as inhibitors of MMP activity [23–25]. MMPs, also known as matrixins, primarily regulated the remodeling of the ECM components, which functions in many pathological conditions such as tumor cell invasion and metastasis, cell growth and differentiation, angiogenesis, and apoptosis [22, 26, 27]. A systematic and comprehensive understanding
of the TIMP-metalloproteinase-substrate network will aid in MMP inhibitor design for therapy. As numerous studies delineated protease-independent TIMP function and protease biology was inherent to various human cancers, advances made in comprehending these versatile metalloproteinase inhibitors could help us defeat cancers. Future efforts will align animal model systems with changes in TIMPs in patients, will, will pinpoint therapeutic targets within the TIMP-metalloproteinase-substrate network and will use TIMPs in liquid biopsy samples as biomarkers for cancer prognosis. Among the family of TIMPs, Wang et al disclosed that TIMP2 participated in the regulation of cell adhesion, angiogenesis, epithelial-to-mesenchymal transition (EMT) and interacted with multiple integrin pathways [28]. Up-regulated TIMP2 expression level in cancer tissues probably played a crucial part in the occurrence of cancers. Additionally, TIMP2 probably exerted their functions in many aspects of tumorigenesis through ECM regulators, degradation of ECM and ECM disassembly.

Cancer immunotherapy has shown substantial and validated therapeutic effects in patients with cancer, including ICI and adoptive cell therapy, manipulating the immune system to discern and assault cancer cells [29, 30]. As introduced previously, TIMP2 was related to TMB, MSI, and neoantigen in varying degrees, providing a theoretical basis for directing patient-specific cancer immunotherapy optimizing clinical benefit of current immunotherapy.

Altogether, our study was conducted using diverse public databases and displayed the expression and clinical significance of TIMP2 in cancers. However, our research has several limitations. Sample numbers of each cancer varied greatly, which may lead to a reduction in the reliability and accuracy of analyses for those cancers with a relatively small sample size. In addition, our analysis failed to account for differences in clinical and sociodemographic characteristics of the individuals. The biological interactions and detailed mechanisms involved need further investigation and experimental confirmation, which will be conducted in future researches. we hope our study may be helpful to potential prognostic markers for the improvement of cancer survival and prognostic accuracy in the future.

Conclusions

Comprehensive understanding of the TIMP2 may have guiding significance for the prognostic judgments, early diagnosis and targeted therapy of in cancer patients. Based on our study, further discovery of the systematic molecular mechanisms that how TIMP2 interacted with different signaling and other molecules or leads to different prognosis of cancer patients can pave a way for more effective tumor diagnosis and serve as a genetic treatment target.
