Diabetes is a leading cause of end-stage renal disease. Therefore, prevention of renal dysfunction is an important treatment goal in the management of diabetes. The data of landmark cardiovascular outcome trials of sodium-glucose cotransporter-2 (SGLT2) inhibitors showed profound reno-protective effects. The Korean Diabetes Association and the Korean Society of Nephrology reviewed clinical trials and performed a meta-analysis to assess the effects of...
SGLT2 inhibitors on the preservation of estimated glomerular filtration rate (eGFR). We limited the data of SGLT2 inhibitors which can be prescribed in Korea. Both eGFR value and its change from the baseline were significantly more preserved in the SGLT2-inhibitor treatment group compared to the control group after 156 weeks. However, some known adverse events were increased in SGLT2 inhibitor treatment, such as genital infection, diabetic ketoacidosis, and volume depletion. We recommend long-term use of SGLT2 inhibitors in patients with type 2 diabetes mellitus (T2DM) for attenuation of renal function decline. However, we cannot generalize our recommendations due to the lack of long-term clinical trials testing the reno-protective effects of every SGLT2 inhibitor in a broad range of patients with T2DM. This recommendation can be revised and updated after the publication of several large-scale renal outcome trials.

**Keywords:** Diabetes mellitus, type 2, Glomerular filtration rate, Renal function, Sodium-glucose transporter-2 inhibitors

**Introduction**

Diabetic kidney disease (DKD) is a global problem and the prevalence and incidence are increasing strikingly. Along with the accelerating incidence of DKD, the total number of patients with end-stage renal disease (ESRD) undergoing maintenance dialysis has grown by approximately 7% to 10% per year in Korea [1–3]. DKD is the most prevalent cause of ESRD (affecting 50.2% of new ESRD patients in 2016) in Korea from 1994 [4]. All current treatment efforts in type 2 diabetes mellitus (T2DM) are devoted to the control of hyperglycemia to prevent the development of micro- and macrovascular complications. The cornerstone of therapy to prevent DKD is the strict control of the blood pressure with the renin-angiotensin—aldosterone system (RAAS) blockade and blood glucose levels [5]. However, many patients with diabetes progress to chronic kidney disease (CKD) despite standard treatment. These kinds of patients usually have profound amounts of albuminuria despite the use of RAAS-blocking agents and renal function declines rapidly. Furthermore, reduced estimated glomerular filtration rate (eGFR) is independently associated with all-cause mortality and cardiovascular disease [6]. There is an unmet clinical need for diabetes treatment to prevent or delay DKD progression.

Sodium-glucose cotransporter-2 (SGLT2) inhibitor is an emerging antidiabetic medication, and its cardio-protective effects has been proven from the large-scale cardiovascular outcome trials of Empagliflozin Cardiovascular Outcome Event Trial in Type 2 Diabetes (EMPA-REG) OUTCOME [7], Canagliflozin Cardiovascular Assessment Study (CANVAS) Program [8], and Dapagliflozin Effect on Cardiovascular Events—Thrombolysis in Myocardial Infarction 58 (DECLARE-TIMI 58) [9]. In these studies, renal outcome was analyzed as a secondary outcome. Empagliflozin showed a 49% reduction of incident or worsening of nephropathy (progression to macroalbuminuria, doubling of the serum creatinine level, initiation of renal-replacement therapy, or death from renal disease) [10], and dapagliflozin reduced 47% of renal-specific outcomes (a sustained decline of at least 40% in eGFR to less than 60 mL/min per 1.73 m$^2$, ESRD, or death from renal or cardiovascular causes) [11]. The Canagliflozin and Renal Endpoints in Diabetes with Established Nephropathy Clinical Evaluation (CREDENCE) trial [12] was the first study to show reno-protective effects as a primary outcome from a large-scale randomized clinical trial (among 4,401 subjects with T2DM). However, canagliflozin is not available in Korea. Therefore, it is necessary to investigate the renal benefits of SGLT2 inhibitors that can be prescribed in Korea [13,14]. In real clinical practice, we monitored patients’ renal functions using eGFR as described in other clinical trials assessed it. Therefore, among various renal outcomes, we aimed to analyze the eGFR after long-term treatment with SGLT2 inhibitors.

**Recent recommendations regarding SGLT2 inhibitor use in patients with T2DM**

In August 2019, the American Diabetes Association revised the online version of the Standards of Medical Care in Diabetes, adopting the results of the CREDENCE trial [15]. It recommended to consider SGLT2 inhibitor treatment in patients with T2DM and CKD (level of evidence C). After that, it updated the recommendation level to level of evidence A and specified the indication of SGLT2 inhibitor for patients with T2DM and DKD with an eGFR.
of at least 30 mL/min per 1.73 m² and albuminuria in 2020 [16]. Diabetes Canada also recommended SGLT2 inhibitor in T2DM with clinical cardiovascular disease and with an eGFR of at least 30 mL/min per 1.73 m² to reduce the risk of progression of CKD (Grade B, level 2 for empagliflozin and Grade C, level 3 for canagliflozin) in 2018 [17]. The Committee of Clinical Practice Guideline of the Korean Diabetes Association updated to the 6th Clinical Practice Guideline in 2019. In this guideline, SGLT2 inhibitor was recommended as a second-line drug, and the committee emphasized its cardioprotective effects [18]. However, it did not yet contain renal outcomes of SGLT2 inhibitor. In this statement, we firstly announced the renoprotective effects of SGLT2 inhibitor considering the situation of Korea.

**Effects of SGLT2 inhibitors on renal function**

Results of cardiovascular outcome trials using SGLT2 inhibitors

Neuen et al [19] reported the meta-analysis data of EMPA-REG Outcome, CANVAS Program, CREDENCE, and DECLARE-TIMI 58. This meta-analysis demonstrated

![Figure 1](www.krcp-ksn.org)

**Figure 1.** Effect of sodium-glucose cotransporter-2 inhibitors (SGLT2i) on (A) estimated glomerular filtration rate (eGFR), and (B) change of eGFR from baseline.

CI, confidence interval; IV, inverse variance; SD, standard deviation.
that SGLT2 inhibitors reduced the risk of ESRD and death due to kidney disease (relative risk of 0.67). This beneficial effect has been shown consistently across baseline eGFR levels in those studies. However, a meta-analysis result excluding the CREDENCE trial showed that the renoprotective effects were attenuated in patients with more advanced renal dysfunction at a baseline eGFR of less than 60 mL/min per 1.73 m² [20]. The inclusion and exclusion criteria of the original randomized clinical trials were not the same. For example, the EMPA-REG trial [10] included subjects with their eGFRs of at least 30 mL/min per 1.73 m², in contrast the DECLARE-TIMI 58 study [11] included subjects whose eGFRs were equal to or higher than 60 mL/min per 1.73 m². In this regard, 25.5% of subjects in the EMPA-REG study and only 7.4% of participants in DECLARE-TIMI 58 had eGFRs that were less than 60 mL/min per 1.73 m². Furthermore, a large number of participants were not followed up, and Asian pa-

**Figure 1. Continued.**
patients made up the minority of participants in each study, including 21.6% in the EMPA-REG study and 13.4% in the DECLARE-TIMI 58 study. For this reason, uncertainty remains about the reno-protective effect of SGLT2 inhibitor in Asian populations with reduced renal function. In this study, we reviewed current evidence considering patients’ baseline renal function and performed a meta-analysis to determine whether SGLT2 inhibitor can be recommended to Korean subjects with T2DM.

**Meta-analysis of large clinical trials using SGLT2 inhibitors**

**Search strategy and selection criteria**

We searched PubMed, Embase, and the Cochrane Central Register of Controlled Library up to March 2020, using search terms including “dapagliflozin,” “empagliflozin,” “ipragliflozin,” and “ertugliflozin,” which are drugs available in Korea. We included long-term large-scale randomized placebo controlled trials whose treatment duration was at least 52 weeks in T2DM patients with more than 100 participants in total. No studies on ipragliflozin and ertugliflozin met these criteria. Finally, we included 12 articles for 11 clinical studies (Supplementary Table 1 and Supplementary Fig. 1, available online) [9,10,21–30]. In this meta-analysis, the final eGFR or delta eGFR from baseline was compared between the SGLT2-inhibitor treatment group and placebo-control according to the method presented in the original studies, and we analyzed the data of low and high doses of empagliflozin separately.

**Figure 2.** Effect of sodium-glucose cotransporter-2 inhibitors (SGLT2i) on change of (A) glycosylated hemoglobin, (B) body weight, (C) systolic blood pressure, and (D) diastolic blood pressure.

CI, confidence interval; IV, inverse variance; SD, standard deviation.
Effect of SGLT2 inhibitor on eGFR

First, we compared the eGFR levels at each time point between the SGLT2 inhibitor and control. As shown in Fig. 1A, SGLT2 inhibitor treatment showed a lower eGFR level than the control at 12 weeks (−1.81 mL/min per 1.73 m²; 95% confidence interval [CI] −3.03 to −0.58) and at 24 weeks (−1.33 mL/min per 1.73 m²; 95% CI, −2.52 to −0.15). However, a favorable effect on eGFR was observed after at least 156 weeks of treatment. At 208 weeks of treatment, the mean difference in eGFR was 3.96 mL/min per 1.73 m² (95% CI, 3.13−4.80) between groups. In general, the improving trend of eGFR was observed in the SGLT2 inhibitor group as the treatment duration was prolonged. In terms of eGFR change from baseline, the mean difference was 1.42 mL/min per 1.73 m² (95% CI, 0.42 to 2.41) at 156 weeks (Fig. 1B). Therefore, SGLT2 inhibitor treatment showed renoprotective effects after long-term treatment.

Effects of SGLT2 inhibitor on glycosylated hemoglobin, body weight, and blood pressure

The glucose-lowering effect of SGLT2 inhibitors was consistently observed: the mean difference in the decline of the glycosylated hemoglobin (HbA1c) was −0.54 (95% CI, −0.67 to −0.41) at 52 weeks and −0.62 (95% CI, −0.75 to −0.48) at 104 weeks, respectively (Fig. 2A). The magnitude of body weight reduction was also greater in the SGLT2 inhibitor treatment than control treatment group (Fig. 2B). Both the systolic and diastolic blood pressure were more significantly decreased in the SGLT2 inhibitor treatment (Fig. 2C, D).

### Table B

Figure 2. Continued 1.
Adverse effects of SGLT2 inhibitor

There was no difference between the SGLT2 inhibitor and control groups in hypoglycemia events and urinary tract infection (Fig. 3A, B). However, more subjects were diagnosed with genital infections (risk ratio [RR], 3.34) (Fig. 3C) and diabetic ketoacidosis (RR, 2.22) (Fig. 3D). Acute kidney injury was less in the SGLT2 inhibitor group than in the control group (RR, 0.71) (Fig. 3E), but volume depletion was slightly more common in the SGLT2 inhibitor group (RR, 1.16) (Fig. 3F).

Effects of SGLT2 inhibitor on renal function among patients with eGFRs of less than 60 mL/min per 1.73 m²

The clinical studies we included for this systemic review and meta-analysis did not enroll a sufficient number of patients with eGFRs of less than 60 mL/min per 1.73 m². The patients with eGFRs of less than 60 mL/min per 1.73 m² included 7.4% of participants in the dapagliflozin study (DECLARE-TIMI 58) and 25.5% of participants in the empagliflozin study (EMPA-REG). Dapagliflozin did not demonstrate the prevention of eGFR decline in patients with eGFRs of less than 60 mL/min per 1.73 m² compared to the placebo group during four years of follow-up (P = 0.053) [11]. This negative result for preventing eGFR decline with dapagliflozin could be due to the insufficient number of enrolled patients with eGFRs of less than 60 mL/min per 1.73 m² since dapagliflozin reduced the rate of eGFR decline in patients with eGFRs of more than 60 mL/min per 1.73 m². In the empagliflozin study, patients with eGFRs of less than 60 mL/min per 1.73 m² treated with empagliflozin showed higher eGFRs compared to the placebo group from 156 weeks, while the analysis with total enrolled patients showed higher eGFRs at 104 weeks (Fig. 4A vs. Fig. 1A). In terms of the eGFR change from baseline, SGLT2 inhibitors showed a beneficial effect at 208-week treatment compared to
the control group (Fig. 4B). Both SGLT2 inhibitor studies revealed the initial decrease of the eGFR after SGLT2 inhibitors treatment since the mechanism of SGLT2 inhibitors may be due to relieving vasodilation of the afferent arteriole and following decrease of glomerular hyperfiltration in diabetes [31]. This initial decrease of the eGFR after SGLT2 inhibitor treatment was more significant in patients with eGFRs of less than 60 mL/min per 1.73 m². The risk of a sustained decrease in eGFR by at least 40% or more and in patients with eGFRs of 59 mL/min per 1.73 m² or less. In our meta-analysis, patients with eGFRs of less than 60 mL/min per 1.73 m² showed less hypoglycemia and more genital infections in SGLT2 inhibitor treatment compared to the control (Supplementary Fig. 2).

Results of Asian-dominant research

We arbitrarily defined Asian-dominant when Asians made up more than 40% of the total subjects. Kaku et al [21] analyzed the subgroup data of the Asian population from the EMPA-REG OUTCOME trial, which was the longest and largest trial included in our meta-analysis. Asian-dominant studies showed no significant difference in eGFR change between groups (Fig. 5A). Only one study was analyzed after 156 weeks of treatment in this meta-

analysis; therefore, it is not conclusive as to whether Asians may experience similar benefits of renal preservation with long-term treatment of SGLT2 inhibitors compared to the non-Asian population. Other parameters, such as HbA1c, body weight, blood pressure, and adverse events were similar with meta-analysis of the total population (Fig. 5B and Supplementary Fig. 3).

Korean Diabetes Association and Korean Society of Nephrology joint consensus statement on the use of SGLT2 inhibitor in T2DM for preservation of renal function

Long-term treatment of SGLT2 inhibitor has a preventive effect on decline of renal function in some patients with T2DM; therefore, long-term treatment of SGLT2 inhibitors is recommended under continuous monitoring of renal function (i.e., eGFR) (weak recommendation, low quality of evidence).

Strength of the recommendation

Study participants were mainly from Western countries. Their baseline body mass index was near 30 kg/m$^2$, which is relatively higher than that of Korean subjects with T2DM. Furthermore, Asian-dominant studies are lacking and a meta-analysis including only Asian-dominant studies did not show statistically significant effects on renal preservation. In addition, only two studies included subjects whose eGFRs were less than 60 mL/min/1.73 m$^2$; therefore, more attention should be paid to this population. In this regard, we cannot recommend the use of SGLT2 inhibitors in all patients with T2DM: more studies assessing renal effects as a primary outcome and including a meaningful number of Asian patients and subjects with a broad range of renal function are necessary. However, the ongoing Dapagliflozin And Prevention of Adverse Outcomes in Chronic Kidney Disease (DAPA-CKD) trial (NCT03036150) and EMPA-KIDNEY study (NCT03594110) are likely to provide further evidence in this field. This recommendation can be revised and updated after publication of these two landmark studies.

Quality of evidence

The authors independently assessed the risk of bias at the study level using the revised Cochrane risk-of-bias...
The mainstay of prevention and treatment for CKD in T2DM included optimal treatment of hyperglycemia, dyslipidemia, obesity, and blood pressure using RAAS blockade. These general recommendations should be followed and the patient’s preferences regarding both the benefits of SGLT2 inhibitors and their possible disadvantages, such as urinary frequency, unwanted body weight loss, genital infections, and cost, should be considered. We should educate patients for preventing volume depletion and genital infection. From the physician’s perspective, an immediate decline in renal function is concerned, and a follow-up plan for monitoring eGFR must be developed.
