METASTABILITY OF REVERSIBLE FINITE STATE MARKOV PROCESSES

J. BELTRÁN, C. LANDIM

Abstract. We prove the metastable behavior of reversible Markov processes on finite state spaces under minimal conditions on the jump rates. To illustrate the result we deduce the metastable behavior of the Ising model with a small magnetic field at very low temperature.

1. Introduction

Metastability is a phenomenon observed in thermodynamic systems close to a first–order phase transition. Describing the evolution among competing metastable states or from a metastable state to a stable state in stochastic lattice spin systems at low temperatures is still a subject of considerable interest. We refer to [10, 22, 3, 11] for recent monographs on the subject.

Inspired from the metastable behavior of condensed zero-range processes [2] and from the metastable behavior of random walks among random traps [15, 16], we proposed in [1] a definition of metastability and developed some techniques, particularly effective in the reversible case, to prove the metastability of sequences of Markov processes on countable state spaces.

To present the approach introduced in [1] in the simplest possible context, we examine in this article the metastable behavior of reversible Markov processes on finite state spaces. The main result of the article, Theorem 2.1, describes all metastable behaviors of such processes in all time scales under the minimal conditions (2.1), (2.2) on the jump rates.

The minimal assumptions (2.1), (2.2) are clearly satisfied by all Markovian dynamics studied so far. This includes the Glauber dynamics with a small external field at very low temperature in two [19, 20] and three [3] dimensions, anisotropic Glauber dynamics [17, 18], conservative Kawasaki dynamics [12, 13, 14, 9], birth and death processes [23] and the reversible dynamics considered in [7].

Theorem 2.1 asserts the existence of time scales in which a metastable behavior is observed. To apply this result to specific models, as pointed out in Remark 2.2, one needs to compute the capacity between metastable sets and the hitting probabilities of metastable sets. In some cases, as in the Kawasaki dynamics, the exact calculation of the hitting probabilities is impossible, but one can at least determine if the asymptotic hitting probability is strictly positive or not. In these cases, an exact description of the metastable behavior of the process is not available. It is only known that asymptotically the process spends an exponential time, of a computable mean, in a metastable set at the end of which it jumps to some

Key words and phrases. Metastability, Finite state Markov processes, Reversibility.
other metastable set with an unknown probability, where the same phenomenon is observed.

In contrast with the pathwise approach proposed in \[5\], the one presented in this article does not highlight the saddle configurations visited by the process when moving from one metastable state to another. However, to compute the exact depths of the valleys, a calculation which relies on a precise estimation of the capacities, one needs to characterize the saddle configurations. This is clearly illustrated in Section \[8\] where the saddle configurations of a valley \(E_\sigma\), denoted by \(\mathcal{W}(\sigma)\), appear when we compute the capacities between the metastable sets of the Ising model.

The lack of precise results on the saddle configurations is compensated by an exact description of the asymptotic dynamics among wells. We are able, in particular, with similar methods to the ones introduced in Bovier et al. \[5, 6\], to show the existence of sequences \(\theta_N\) for which \(T_N/\theta_N\) converges to a mean one exponential distribution, if \(T_N\) represents the time the process leaves a metastable set. Furthermore, we also prove the asymptotic independence of \(T_N/\theta_N\) and \(\eta_{TN}\), where \(\eta\) represents the Markov process, a question not considered before. The proof of this asymptotic independence requires the convergence of the average jump rates, defined in \(2.4\), which is, in most cases, the main technical difficulty in the deduction of metastability.

To illustrate the main result, we consider in Section \[3\] the metastable behavior of the two dimensional Ising model with a small external field at very low temperature, the model of Neves and Schonmann \[19, 20\], and a case in which all parameters can be exactly computed.

2. Notation and Results

We say that a sequence of positive real numbers \((\alpha_N : N \geq 1)\) is of lower magnitude than a similar sequence \((\beta_N : N \geq 1)\), \(\alpha_N \prec \beta_N\) or \(\beta_N \succ \alpha_N\), if \(\alpha_N/\beta_N\) vanishes as \(N \uparrow \infty\). We say that two positive sequences \((\alpha_N : N \geq 1), (\beta_N : N \geq 1)\) are of the same magnitude, \(\alpha_N \approx \beta_N\), if there exists a finite positive constant \(C_0\) such that

\[
C_0^{-1} \leq \liminf_{N \to \infty} \frac{\alpha_N}{\beta_N} \leq \limsup_{N \to \infty} \frac{\alpha_N}{\beta_N} \leq C_0.
\]

Finally, \(\alpha_N \preceq \beta_N\) or \(\beta_N \succeq \alpha_N\) means that \(\alpha_N \prec \beta_N\) or \(\alpha_N \approx \beta_N\).

We say that a set of sequences \((\alpha_N(1) : N \geq 1), \ldots, (\alpha_N(\ell) : N \geq 1)\) is comparable if for each \(i \neq j\) one of the three possibilities holds: either \(\alpha_N(i) \prec \alpha_N(j)\) or \(\alpha_N(j) \prec \alpha_N(i)\) or \(\alpha_N(i)/\alpha_N(j)\) converges to a constant \(c_{i,j} \in (0, \infty)\). Hence, for example, the possibility that the sequence \(\alpha_N(i)/\alpha_N(j)\) oscillates between two finite values and does not converge is excluded.

Fix a finite set \(E\) and sequences \(\{\lambda_N(j) : N \geq 1\}, 0 \leq j \leq n\), such that \(\lambda_N(n) \prec \lambda_N(n-1) \prec \cdots \prec \lambda_N(0) \equiv 1\). Consider a Markov process \(\eta_t^N : t \geq 0\) on \(E\) with jump rates denoted by \(R_N(x,y), x \neq y \in E\). We assume that the process is irreducible, that the unique stationary state, denoted by \(\mu_N\), is reversible, and that the jump rates satisfy the following multi-scale hypothesis. There exists \(a : E \times E \to \{0, \ldots, n\}\) such that

\[
R_N(x,y) = r_N(x,y) \lambda_N(a(x,y)) , \quad x \neq y \in E ,
\]

where \(\lim_{N \to \infty} r_N(x,y) = r(x,y) \in (0, \infty), x \neq y\). We assume, without loss of generality, that \(a(x,y) = 0\) for some \(x \neq y\). We assume, furthermore, that
products of the rates $\lambda_N(j)$ are comparable. More precisely, we suppose that for any $(k_1, \ldots, k_n) \in \mathbb{Z}^n$,

$$\lim_{N \to \infty} \prod_{i=1}^{n} \lambda_N(i)^{k_i} = C_0$$

(2.2)

for some constant $C_0 \in [0, \infty]$ which depends on $(k_0, \ldots, k_n)$.

Fix two states $x, y$ in $E$. By irreducibility, there exists a path $x = x_0, x_1, \ldots, x_n = y$ such that $n \leq |E|$, $R_N(x_i, x_{i+1}) > 0$, $0 \leq i < n$. By the detailed balance condition,

$$\frac{\mu_N(y)}{\mu_N(x)} = \prod_{i=0}^{n-1} \frac{R_N(x_{i+1}, x_i)}{R_N(x_i, x_{i+1})}.$$  

(2.3)

It follows from assumptions (2.1) and (2.2) that the sequences $\{\mu_N(x) : N \geq 1\}$, $x \in E$, are comparable. In fact, there exist $m \geq 1$, sequences $M_N(m) \prec \cdots \prec M_N(1) \prec M_N(0) \equiv 1$, a function $b : E \to \{0, \ldots, m\}$ and a function $m : E \to (0, \infty)$ such that

$$\mu_N(x) = m_N(x) M_N(b(x)),$$  

(2.4)

where $\lim_{N \to \infty} m_N(x) = m(x) \in (0, \infty)$. We may choose each sequence $M_N(j)$ to be equal to $\prod_{i=1}^{n} \lambda_i(N)^{k_i}$ for an appropriate choice of $(k_1, \ldots, k_n)$ with $\sum_i |k_i| \leq 4|E|$.

Let $G_N : E \times E \to \mathbb{R}_+$ be given by $G_N(x, y) = \mu_N(x) R_N(x, y)$ and note that $G_N$ is symmetric. As above, by (2.1) and (2.2) the sequences $\{G_N(x, y) : N \geq 1\}$, $x \neq y \in E$, are comparable. Moreover, there exist $j \geq 1$, sequences $G_N(j) \prec \cdots \prec G_N(1) \prec G_N(0) \equiv 1$, a function $c : E \times E \to \{0, \ldots, j\}$ and a function $g : E \to (0, \infty)$ such that

$$G_N(x, y) = g_N(x, y) G_N(c(x, y)),$$  

(2.5)

where $\lim_{N \to \infty} g_N(x, y) = g(x, y) \in (0, \infty)$. Here also each sequence $G_N(j)$ may be chosen equal to $\prod_{i=1}^{n} \lambda_i(N)^{k_i}$ for an appropriate choice of $(k_1, \ldots, k_n)$ with $\sum_i |k_i| \leq 4|E| + 1$.

Denote by $P^N_x$, $x \in E$, the probability measure on the path space $D(\mathbb{R}_+, E)$ induced by the Markov process $\{\eta^N_t : t \geq 0\}$ starting from $x$. Expectation with respect to $P^N_x$ is denoted by $E^N_x$.

For a subset $A$ of $E$, denote by $T_A$ the hitting time of $A$:

$$T_A = \inf\{t > 0 : \eta^N_t \in A\}.$$  

When $A$ is a singleton $\{x\}$, we denote $T_{\{x\}}$ by $T_x$.

For a proper subset $F$ of $E$, denote by $\{\eta^F_t : t \geq 0\}$ the trace of the Markov process $\{\eta^N_t : t \geq 0\}$ on $F$. We refer to [1] Section 2] for a precise definition. $\eta^F_t$ is a Markov process on $F$ and we denote by $R^F_N(x, y)$, $x, y \in F$, its jump rates. Let $r^F_N(A, B)$, $A, B \subset F$, $A \cap B = \emptyset$, be the average jump rates of $\eta^F_t$ from $A$ to $B$:

$$r^F_N(A, B) = \frac{1}{\mu_N(A)} \sum_{x \in A} \mu_N(x) \sum_{y \in B} R^F_N(x, y).$$  

(2.6)

The main theorem of this article describes all metastable behaviors of the process $\{\eta^N_t : t \geq 0\}$.

**Theorem 2.1.** There exist $\mathfrak{M} \geq 1$, sequences $\{\theta_N(k) : N \geq 1\}$, $1 \leq k \leq \mathfrak{M}$, $1 \leq \theta_N(1) \prec \cdots \prec \theta_N(\mathfrak{M})$, and, for each $1 \leq k \leq \mathfrak{M}$, a partition $E_1^{(k)}, \ldots, E_\nu^{(k)}$, $\Delta_k$ of the state space $E$ such that for all $1 \leq k \leq \mathfrak{M}$:
(P1) $1 < \nu(k) < \nu(k-1)$, $k \geq 2$.

(P2) For $k \geq 2$, $1 \leq i \leq \nu(k)$, $E_i^{(k)} = \cup_{a \in I_k, i} E_a^{(k-1)}$, where $I_k,1, \ldots, I_{k,\nu(k)}$ are disjoint subsets of $\{1, \ldots, \nu(k-1)\}$.

(P3) For $1 \leq i \leq \nu(k)$, $\mu_N(x) = \mu_N(E_i^{(k)})$ for all states $x$ in $E_i^{(k)}$.

(P4) Let $E_i^{(k)} = \cup_{i=1}^{\nu(k)} E_i^{(k)}$. For all $1 \leq i \neq j \leq \nu(k)$, the following limits exist

$$v_k(i,j) := \lim_{N \to \infty} \theta_N(k)^{-1} \rho_N^{(k)}(E_i^{(k)}, E_j^{(k)}) .$$

(P5) Property (M1) of metastability holds: For every $1 \leq i \leq \nu(k)$, every state $x$ in $E_i^{(k)}$ and every $\delta > 0$,

$$\lim_{N \to \infty} \max_{y \in E_i^{(k)}} P_N^y \left[ T_x > \delta \theta_N(k) \right] = 0 .$$

(P6) Property (M2) of metastability holds: Let $\Psi_k : E^{(k)} \to \{1, \ldots, \nu(k)\}$ be given by

$$\Psi_k(x) = \sum_{i=1}^{\nu(k)} i \mathbf{1}\{x \in E_i^{(k)}\} .$$

Denote by $\{\eta_t^{N,k} : t \geq 0\}$ the trace of the process $\{\eta_t^N : t \geq 0\}$ on $E^{(k)}$. For every $1 \leq i \leq \nu(k)$, $x \in E_i^{(k)}$, under the measure $P_N^x$, the blind speeded up (non-Markovian) process $X^{N,k}_t = \Psi_k(\eta_{t\theta_N(k)})$ converges to the Markov process on $\{1, \ldots, \nu(k)\}$ starting from $i$ and characterized by the rates $v_k(i,j)$.

(P7) Property (M3) of metastability holds: For every $t > 0$,

$$\lim_{N \to \infty} \max_{x \in E} E_N^x \left[ \int_0^t \mathbf{1}\{\eta_s^{N,k} \in \Delta_k\} ds \right] = 0 .$$

The sets $E_i^{(k)}$, $1 \leq i \leq \nu(k)$, are called the metastable states at level $k$ or, simply, $k$-metastates. Property (P2) asserts that as we pass from a description in the time scale $\theta_N(k-1)$ to a description in the longer time scale $\theta_N(k)$, the new metastates are larger and obtained as unions of $(k-1)$-metastates. Moreover, by property (P3), all states in any metastable set have measure of the same magnitude.

Condition (P5) asserts that, with a probability increasing to one, any state in a metastable set is visited before the process leaves the metastable set. The process therefore thermalizes in the metastable state or, in other words, reaches a local equilibrium, before leaving the metastable state.

Condition (P7) states that on the time scale $\theta_N(k)$, the time spent outside the union of all metastates is negligible. To examine the behavior of the process in this time scale we may therefore restrict our attention to the trace process $\{\eta_t^{N,k} : t \geq 0\}$ speeded up by $\theta_N(k)$.

It follows from properties (P5) and (P6) that the speeded up trace process $\{\eta_{t\theta_N(k)}^{N,k} : t \geq 0\}$ thermalizes in each metastable set $E_i^{(k)}$ and then, at the end of an exponential time, jumps to another metastable set. By property (P4) the rate at which the process jumps from one metastable set to another is given by the asymptotic mean rate at which the speeded up trace process jumps. Theorem 2.1 gives, therefore, a complete description of the evolution of the process on each time scale $\theta_N(k)$.

Remark 2.2. In order to apply this result to concrete models, we proceed as follows. Consider the Markov process on $E$ obtained by suppressing all jumps
comparable the following limits exist

\[ \theta_{N,i} = \frac{\mu_N(E_i)}{\text{cap}_N(E_i, \bar{E}_i)}, \quad 1 \leq i \leq \nu, \]  

(2.7)

where \( \text{cap}_N(A, B) \) represents the capacity between \( A \) and \( B \), defined in Section 4 and \( \bar{E}_i = \cup_{j \neq i} E_j \). By Proposition 5.8 the sequences \( (\theta_{N,i} : N \geq 1), 1 \leq i \leq \nu, \) are comparable. Let \( \theta_N = \theta_N(1) = \min\{\theta_{N,i} : 1 \leq i \leq \nu\} \). Since the sequences are comparable the following limits exist

\[ \lambda(i) = \lim_{N \to \infty} \frac{\theta_{N,i}}{\theta_{N,i}} \in [0, \infty), \quad 1 \leq i \leq \nu. \]

(2.8)

By Lemma 4.3 and the first remark formulated at the end of Section 6, for every \( 1 \leq i \neq j \leq \nu \), the limits below also exist and do not depend on \( x \in E_i \):

\[ p(i, j) = \lim_{N \to \infty} P_x^N \left[T_{E_j} = T_{E_i}\right]. \]

(2.9)

By \( (2.2) \), \( \tau_1(i, j) = \lambda(i)p(i, j) \).

Hence, the characterization of the 1-metastates is very simple and the computation of \( \theta_{N,i} \) (the depth of the valley \( E_i \), as we shall see) is feasible. This computation provides the slowest time scale \( \theta_N(1) \) in which a metastable behavior is observed. To determine the exact asymptotic evolution in this time scale, we need to compute \( (2.8) \) which may be difficult or even impossible. In several cases, however, one may at least discriminate the pairs \((i, j)\) for which \( \tau_1(i, j) \) is strictly positive. This permits to iterate the argument and gives an imprecise picture of the metastable behavior. In the time scale \( \theta_N(1) \) the process remains in the 1-metastate \( E_i \) for a rate \( \lambda(i) \) exponential time at the end of which it jumps to one of the remaining metastates such that \( p(i, j) > 0 \).

Consider the Markov process on \( \{E_1, \ldots, E_\nu\} \) (instead of \( \{1, \ldots, \nu\} \)) with rates \( \tau_1(i, j) \) and denote by \( \nu(2) \) the number of its irreducible classes, and by \( E^{(2)}_1, \ldots, E^{(2)}_\nu \) the irreducible classes. Note that properties (P1) and (P2) are fulfilled and that we need only to know if \( p(i, j) \) is strictly positive or not to determine the irreducible classes. Compute \( (2.7) \) and \( (2.8) \) for this new class of sets to obtain the second time scale \( \theta_N(2) \) and the rates \( \tau_2(i, j) \). Iterating this scheme we completely characterize the metastable behavior of the Markov process.

We conclude this section with some comments. In statistical mechanics models, the rates \( R_N(x, y) \) are usually exponential and given by \( e^{Nh(x, y)} \) for some function \( h : E \times E \to \mathbb{R} \). Assumptions \( (2.1), (2.2) \) are trivially satisfied in this context.

In some models examined in statistical mechanics the time scales \( \theta_N(k), 1 \leq k < \mathfrak{M} \), correspond to the nucleation phase of the system, which may be very intricate even for simple dynamics due to the variety of valleys and the complexity of their geometries. In most case, one only investigates the behavior in the largest time scale, \( \theta_N(\mathfrak{M}) \), where one observes either an exponential jump from a metastable to a stable state, or a Markovian evolution among competing metastable states.

We prove in \( (6.3) \) and \( (7.1) \) that the process never jumps from a metastable set to another metastable set which has probability of smaller order: \( \tau_k(i, j) = 0 \) if \( \mu_N(E^{(k)}_j) < \mu_N(E^{(k)}_i) \).
3. The Ising model at low temperature

To illustrate the methods presented in the first part of this article, we examine in this section the metastable behavior of the Ising model at low temperature following Neves and Schonmann [19].

We consider the two-dimensional nearest neighbor ferromagnetic Ising model on a finite torus \( \Lambda_L = \mathbb{T}_L \times \mathbb{T}_L \), \( L \geq 1 \), where \( \mathbb{T}_L = \{1, \ldots, L\} \) is the discrete one-dimensional torus with \( L \) points. The Hamiltonian is written as

\[
\mathbb{H}(\sigma) = -\frac{1}{2} \sum_{(x,y)} \sigma(x)\sigma(y) - \frac{h}{2} \sum_{x \in \Lambda_L} \sigma(x),
\]

where \( \sigma(x) \in \{-1,1\} \), the first sum runs over the pairs of nearest neighbors sites of \( \Lambda_L \), counting each pair only once, and the second is taken over \( \Lambda_L \). We will always consider \( h > 0 \).

At inverse temperature \( \beta > 0 \), the Gibbs measure \( \mu_\beta \) associated to the Hamiltonian \( \mathbb{H} \) is given by

\[
\mu_\beta(\sigma) = \frac{1}{Z_\beta} e^{-\beta \mathbb{H}(\sigma)},
\]

where \( Z_\beta \) is the normalizing partition function.

The Glauber dynamics on the state space \( \Omega = \Omega_L = \{-1,1\}^{\Lambda_L} \), also known as the Ising model, is the continuous-time Markov process whose generator \( L_\beta \) acts on functions \( f: \Omega \to \mathbb{R} \) as

\[
(L_\beta f)(\sigma) = \sum_{x \in \Lambda_L} c(x,\sigma) \left[ f(\sigma^x) - f(\sigma) \right],
\]

where \( \sigma^x \) is the configuration obtained from \( \sigma \) by flipping the spin at \( x \):

\[
\sigma^x(y) = \begin{cases} 
\sigma(y) & \text{if } y \neq x, \\
-\sigma(x) & \text{if } y = x,
\end{cases}
\]

where the rates \( c(x,\sigma) \) are given by

\[
c(x,\sigma) = \exp \left\{ -\beta \left[ \mathbb{H}(\sigma^x) - \mathbb{H}(\sigma) \right] \right\},
\]

and where \( a_+ \), \( a \in \mathbb{R} \), stands for the positive part of \( a \): \( a_+ = \max\{a,0\} \).

The Markov process \( \{\sigma_\beta^t : t \geq 0\} \) with generator \( L_\beta \) is reversible with respect to the Gibbs measures \( \mu_\beta \), \( \beta > 0 \), and ergodic. Denote by \( R_\beta(\sigma,\sigma') \) the rate at which the process jumps from \( \sigma \) to \( \sigma' \) so that \( R_\beta(\sigma,\sigma') \) vanishes unless \( \sigma' = \sigma^x \) for some \( x \in \Lambda_L \), in which case \( R_\beta(\sigma,\sigma^x) = c(x,\sigma) \).

In this model the process jumps from a state \( \sigma \) to the state \( \sigma^x \) at rate 1 if \( \mu_\beta(\sigma) \leq \mu_\beta(\sigma^x) \). In particular, by the detailed balance condition, \( \mu_\beta(\sigma) R_\beta(\sigma,\sigma^x) = \min\{\mu_\beta(\sigma), \mu_\beta(\sigma^x)\} \) so that \( G_\beta(\sigma,\sigma') = \min\{\mu_\beta(\sigma), \mu_\beta(\sigma^x)\} \).

We examine in this section the metastable behavior of the Markov process \( \{\sigma_\beta^t : t \geq 0\} \) on \( \Omega \) as the temperature vanishes. To avoid less interesting cases, following [19] we assume from now on that \( 0 < h < 2 \), that \( 2/h \notin \mathbb{N} \) and that \( L > (n_0+1)^2+1 \), where \( n_0 = \lfloor 2/h \rfloor \) and \( \lceil r \rceil \) stands for the integer part of \( r \).

Let \( I \) be an interval of the one-dimensional torus \( \mathbb{T}_L \). The sets \( I \times \mathbb{T}_L, \mathbb{T}_L \times I \subset \Lambda_L \) are called rings, while rectangles are subsets of the form \( I \times J \), where \( I, J \) are non-empty proper intervals of \( \mathbb{T}_L \).

To describe all metastable behaviors of the Ising model, we need to define the time scales at which they occur, the metastable sets associated to each time scale,
and the asymptotic dynamics which specifies at which rate the process jumps from one metastable state to another. We start defining the $n_0 + 1$ time scales. For $1 \leq k \leq n_0 - 1$ let

$$
\theta_\beta(k) = e^{k \beta h}, \quad \theta_\beta(n_0) = e^{\beta(2-h)}, \quad \theta_\beta(n_0 + 1) = e^{\beta c(h)},
$$

where $c(h) = 4(n_0 + 1) - h[(n_0 + 1)n_0 + 1]$. Note that $\theta_\beta(1) \propto \cdots \propto \theta_\beta(n_0 + 1)$.

The presentation of the metastable sets requires some notation. Denote by $\Omega_o \subset \Omega$ the set of configurations whose total jump rate $\sum_{x \in \Lambda_L} R_\beta(\sigma, \sigma')$ vanishes as $\beta \uparrow \infty$. This is the set of configurations in which a negative spin has at most one positive neighbor and in which a positive spin has at most two negative neighbors. This set contains the configurations $+1, -1$, which are the configurations with all spins positive, negative, respectively, and configurations formed by positive rectangles and rings of length and width larger than 2 in a background of negative spins. In these latter configurations, to fulfill the prescribed conditions the positive rectangles and rings may not be at graph distance 2.

For a configuration $\sigma$ in $\Omega_o$, denote by $\ell(\sigma)$ the smallest length or width of the positive rectangles of $\sigma$. By convention, $\ell(-1) = 0$, $\ell(+1) = L$ and $\ell(\sigma) = L$ if $\sigma$ contains no positive rectangles, but only positive rings. Let $N_r(\sigma)$ be the number of positive rectangles of $\sigma \times m$ rectangles of $\sigma$ for some $m > \ell(\sigma)$, and let $N_s(\sigma)$ be the number of positive rectangles of $\sigma$.

We may now introduce the metastable states $\Omega_{o,k}$ appearing in the time scale $\theta_\beta(k)$, $1 \leq k \leq n_0 + 1$. For $1 \leq k \leq n_0$, let

$$
\Omega_{o,k} = \{ \sigma \in \Omega_o : \ell(\sigma) > k \} \cup \{-1\}, \quad \Omega_{o,n_0+1} = \{+1, -1\}.
$$

Note that $\Omega_o = \Omega_{o,1} \supset \cdots \supset \Omega_{o,n_0+1}$. The metastables states appearing in the time scale $\theta_\beta(k)$, $1 \leq k \leq n_0 + 1$, are all the elements of $\Omega_{o,k}$.

To depict how the process jumps from one metastable state to another in the different time scales, we need to introduce several sets. We use the terminology of graph theory to name some of them. Denote by $\mathbb{D}(\sigma)$ the set of direct successors of the configuration $\sigma$ in $\Omega_o$, $\sigma \neq +1, -1$. If $\ell(\sigma) = 2$, $\mathbb{D}(\sigma)$ is the set of configurations obtained from $\sigma$ by flipping all positive spins from one of the two sides of length 2 of a positive $2 \times m$ rectangle, $m > 2$, and of configurations obtained from $\sigma$ by flipping all spins of a positive $2 \times 2$ square of $\sigma$. Clearly, $|\mathbb{D}(\sigma)| = 2N_r(\sigma) + N_s(\sigma)$. When $3 \leq \ell(\sigma) \leq n_0$, $\mathbb{D}(\sigma)$ is the set of configurations obtained from $\sigma$ by flipping all positive spins from one of the sides of length $\ell(\sigma)$ of a positive $\ell(\sigma) \times m$ rectangle, $m \geq \ell(\sigma)$. In this case, $|\mathbb{D}(\sigma)| = 2N_r(\sigma) + 4N_s(\sigma)$. For $\ell(\sigma) > n_0$, $\mathbb{D}(\sigma)$ is the set of configurations obtained by first flipping a negative spin from a site which has a neighbor site with a positive spin, and then flipping in any order all negative spins surrounded by two positive spins. Note that in this latter case two or more positive rectangles may be replaced by the smallest rectangle which contains them all. For this reason an exact description of the direct successors of a configuration in the case $\ell(\sigma) > n_0$ is more complicated.

For $\sigma \in \Omega_o$, $\sigma \neq \pm 1$, denote by $\mathbb{W}(\sigma)$ the set of saddle points of the configuration $\sigma$. For $2 \leq \ell(\sigma) \leq n_0$, $\mathbb{W}(\sigma)$ is the set of configurations obtained from $\sigma$ by flipping $\ell(\sigma) - 1$ positive spins from a side of length $\ell(\sigma)$ of a positive $\ell(\sigma) \times m$ rectangle of $\sigma$, $m \geq \ell(\sigma)$. Note that $|\mathbb{W}(\sigma)| = 2\ell(\sigma)N_r(\sigma) + 4\ell(\sigma)N_s(\sigma)$ for $3 \leq \ell(\sigma) \leq n_0$ and $|\mathbb{W}(\sigma)| = 4N_r(\sigma) + 4N_s(\sigma)$ for $\ell(\sigma) = 2$. For $\ell(\sigma) > n_0$, $\mathbb{W}(\sigma)$ consists of the set of configurations obtained from $\sigma$ by flipping a negative spin from a site which has one neighbor with a positive spin so that $|\mathbb{W}(\sigma)|$ is equal to the sum of the
perimeters of the positive rectangles of \( \sigma \) added to \( 2L \) times the number of positive rings of \( \sigma \).

For \( \ell(\sigma) > n_0 \), let \( \mathcal{W}(\sigma, \sigma') \), \( \sigma, \sigma' \in \Omega_\sigma \), be the subset of \( \mathcal{W}(\sigma) \) of all configurations which attain \( \sigma' \) by flipping in any order all negative spins surrounded by two positive spins, and let \( \mathcal{W}_j(\sigma) \), \( 1 \leq j \leq 3 \), be the configurations \( \xi \) of \( \mathcal{W}(\sigma) \) with the following property. The site where \( \xi \) differs from \( \sigma \) has 3 neighbors with negative spins. Among these three neighbors, \( j \) sites have two neighbors with positive spins. The case \( j = 3 \) occurs when the configuration has two positive rectangles or rings at distance 3. Let \( \mathcal{W}_j(\sigma, \sigma') = \mathcal{W}_j(\sigma) \cap \mathcal{W}(\sigma, \sigma') \).

Fix a configuration \( \sigma \in \Omega_o \) and let \( \Omega_o = \Omega_o \setminus \{ \sigma \} \). Recall that we denote by \( T_\sigma \) the hitting time of a set \( A \subset \Omega \). We prove in Lemma 8.2 that \( P_{\sigma}|_A \) converges, as \( \beta \uparrow \infty \), to 1 and that the process reaches \( \sigma' \) by first visiting a configuration of \( \mathcal{W}(\sigma) \).

Denote by \( \mathcal{S}(\sigma) \) the set of successors of the configuration \( \sigma \) in \( \Omega_o \), \( \sigma \neq +1, -1 \). The difference between a successor and a direct successor is that the critical length \( \ell(\sigma') \) of a successor \( \sigma' \) may not be smaller than the one of the original configuration: \( \ell(\sigma') \geq \ell(\sigma) \). If \( \ell(\sigma) = 2 \) or \( \ell(\sigma) > n_0 \), the set of successors coincides with the set of direct successors: \( \mathcal{S}(\sigma) = \mathcal{D}(\sigma) \). However, if \( 3 \leq \ell(\sigma) \leq n_0 \), \( \mathcal{S}(\sigma) \) is the set of configurations obtained from \( \sigma \) by flipping all positive spins from one of the two sides of length \( \ell(\sigma) \) of a positive \( \ell(\sigma) \times m \) rectangle of \( \sigma \), \( m > \ell(\sigma) \), and of configurations obtained from \( \sigma \) by flipping all spins of a positive \( \ell(\sigma) \times \ell(\sigma) \) square of \( \sigma \).

The probability measure \( p \) introduced below describes how the process jumps from one metastable state to another in the appropriate time scales. For each configuration \( \sigma \in \Omega_o \), define the probability measure \( p(\sigma, \cdot) \) on \( \Omega_o \) as follows. Let \( p(\sigma, \sigma') = 0 \) for \( \sigma' \notin \mathcal{S}(\sigma) \). For \( \sigma' \in \mathcal{S}(\sigma) \) and \( \ell(\sigma) = 2 \leq n_0 \), let

\[
p(\sigma, \sigma') = \begin{cases} \frac{(8/3)|N_r + (8/3)N_s|}{2N_r + (8/3)N_s} & \text{for } \sigma' \in \mathcal{S}_s(\sigma), \\ (2N_r + (8/3)N_s)^{-1} & \text{otherwise} \end{cases}
\]  

(3.1)

where \( \mathcal{S}_s(\sigma) \subset \mathcal{S}(\sigma) \) is the set of configurations obtained from \( \sigma \) by flipping all spins in a positive \( 2 \times 2 \) square of \( \sigma \). For \( \sigma' \in \mathcal{S}(\sigma) \) and \( 3 \leq \ell(\sigma) \leq n_0 \), let

\[
p(\sigma, \sigma') = \begin{cases} \frac{4|N_r + 4N_s|}{2N_r + 4N_s} & \text{for } \sigma' \in \mathcal{S}_s(\sigma), \\ (2N_r + 4N_s)^{-1} & \text{otherwise} \end{cases}
\]  

(3.2)

where \( \mathcal{S}_s(\sigma) \subset \mathcal{S}(\sigma) \) is the set of configurations obtained from \( \sigma \) by flipping all spins in a positive \( \ell(\sigma) \times \ell(\sigma) \) square of \( \sigma \). Finally, for \( \sigma' \in \mathcal{S}(\sigma) \) and \( \ell(\sigma) > n_0 \), let

\[
p(\sigma, \sigma') = \frac{\sum_{j=1}^3 \frac{1}{j+1} |\mathcal{W}_j(\sigma, \sigma')|}{\sum_{j=1}^3 \frac{1}{j+1} |\mathcal{W}_j(\sigma)|}.
\]  

(3.3)

It remains to describe the rates at which the process leaves a metastable state in the different time scales. Let \( \theta : \Omega_o \setminus \{-1, +1\} \to \mathbb{R}_+ \) be given by

\[
\theta(\sigma) = \begin{cases} (2/3)N_s(\sigma) + 2N_r(\sigma) & \text{if } \ell = 2 \leq n_0, \\ \frac{2}{\ell + 1} |\mathcal{W}(\sigma)| & \text{if } 3 \leq \ell \leq n_0, \\ (1/2) |\mathcal{W}_1(\sigma)| + (2/3) |\mathcal{W}_2(\sigma)| + (3/4) |\mathcal{W}_3(\sigma)| & \text{if } \ell > n_0. \end{cases}
\]  

(3.4)
We are now in a position to state the first main result of this section. Fix $1 \leq k \leq n_0 + 1$ and denote by $\sigma_{t}^{\beta,k}$ the trace of the process $\sigma_{t}^{\beta}$ on $\Omega_{\sigma,k}$. Recall that $\sigma_{t}^{\beta,k}$ is a Markov process on $\Omega_{\sigma,k}$.

**Theorem 3.1.** Fix $1 \leq k \leq n_0$. As $\beta \uparrow \infty$, the Markov process $\sigma_{t}^{\beta,k}$ converges to the Markov process on $\Omega_{\sigma,k}$ with jump rates $\tau$ given by

$$
\tau(\sigma, \sigma') = \begin{cases} 
\theta(\sigma)p(\sigma, \sigma') & \text{if } \sigma \in \Omega_{\sigma,k} \setminus \Omega_{\sigma,k+1}, \\
0 & \text{if } \sigma \in \Omega_{\sigma,k+1}.
\end{cases}
$$

Moreover, the time spent outside $\Omega_{\sigma,k}$ by the process $\sigma_{t}^{\beta,k}$ is negligible: for all $t > 0$ and $\sigma \in \Omega$,

$$
\lim_{\beta \to \infty} E_{\sigma}^\beta \left[ \int_0^t 1\{\sigma_{st}^{\beta,k} \notin \Omega_{\sigma,k}\} \, ds \right] = 0.
$$

Fix a configuration $\sigma \in \Omega_{\sigma,k}$, $1 \leq k \leq n_0 - 1$, and consider asymptotic behavior, as the temperature vanishes, of the trace process $\sigma_{t}^{\beta,k}$ in the time scale $\theta_{\beta}(k)$ starting from $\sigma$. Theorem 3.1 states that if $\ell(\sigma) > k + 1$, the configuration $\sigma$ is an absorbing point for the asymptotic dynamics, while if $\ell(\sigma) = k + 1$, the asymptotic dynamics visits a sequence of configurations where each element of the sequence differs from the previous one either by flipping all positive spins of one of the two sides of length $k + 1$ of a $(k + 1) \times m$ positive rectangle, $m > k + 1$, or by flipping all spins of a $(k+1) \times (k+1)$ positive square. After a finite number of jumps, the process reaches a configuration whose positive rectangles have all sides larger than $k + 1$ and stays there forever.

For a configuration $\sigma \in \Omega_{\sigma,n_0}$, Theorem 3.1 states that in the time scale $\theta_{\beta}(n_0)$ the trace process $\sigma_{t}^{\beta,n_0}$ sees its positive rectangles and rings to increase gradually until the configurations $+1$ is reached.

This result describes therefore the behavior of the Ising model in the intermediate scales where first the small positive droplets are removed and then the large positive droplets increase to eventually occupy all space. To complete the picture of the metastable behavior of the model it remains to specify how the process jumps from the configuration $-1$ to the configuration $+1$.

Denote by $W(-1)$ the set of configurations which have a positive $(n_0 + 1) \times n_0$ rectangle and an extra positive spin which has a positive neighbor sitting on one of the sides of length $n_0 + 1$ of the positive rectangle, all others spins being negative. All configurations of $W(-1)$ have the same measure. Denote by $W_{1}(-1)$ the configurations of $W(-1)$ whose extra positive spin is next to the corner of the positive rectangle and by $W_{2}(-1)$ the other configurations of $W_{1}(-1)$. Let

$$
\theta(-1) = (1/2) |W_{1}(-1)| + (2/3)|W_{2}(-1)|.
$$

**Theorem 3.2.** As $\beta \uparrow \infty$, the Markov process $\sigma_{t}^{\beta,n_0+1}$ converges to the Markov process on $\{-1,+1\}$ in which $+1$ is an absorbing state and which jumps from $-1$ to $+1$ at rate $\theta(-1)$. Moreover, the time spent outside $\{-1,+1\}$ by the process $\sigma_{t}^{\beta,n_0+1}$ is negligible: for all $t > 0$ and $\sigma \in \Omega$,

$$
\lim_{\beta \to \infty} E_{\sigma}^{\beta} \left[ \int_0^t 1\{\sigma_{st}^{\beta,n_0+1} \neq \pm 1\} \, ds \right] = 0.
$$
4. Capacities and hitting times

Denote by $D_N$ the Dirichlet form associated to the generator of the Markov process introduced in Section 2:

$$D_N(f) = \sum_{\{x,y\} \in E} \mu_N(x) R_N(x,y) (f(y) - f(x))^2, \quad f : E \to \mathbb{R},$$

where in the sum on the right hand side each bond $\{x,y\}$ is counted only once. Let $\text{cap}_N(A,B)$, $A, B \subset E$, $A \cap B = \emptyset$, be the capacity between $A$ and $B$:

$$\text{cap}_N(A,B) = \inf_{f} D_N(f),$$

where the infimum is carried over all functions $f : E \to \mathbb{R}$ such that $f(x) = 1$ for all $x \in A$, and $f(x) = 0$ for all $x \in B$.

We may compute the order of magnitude of the capacity between two disjoint subsets of $E$. A self-avoiding path $\gamma$ from $A$ to $B$, $A, B \subset E$, $A \cap B = \emptyset$, is a sequence of sites $(x_0, x_1, \ldots, x_n)$ such that $x_0 \in A$, $x_n \in B$, $x_i \neq x_j$, $i \neq j$, $R_N(x_i, x_{i+1}) > 0$, $0 \leq i < n$. Denote by $\Gamma_{A,B}$ the set of self-avoiding paths from $A$ to $B$ and let

$$G_N(A,B) := \max_{\gamma \in \Gamma_{A,B}} G_N(\gamma), \quad G_N(\gamma) := \min_{0 \leq i < n} G_N(x_i, x_{i+1}).$$

Note that there might be more than one optimal path and that $G_N(\{\}, \{\}) \geq G_N(x,y)$, with possibly a strict inequality.

We shall say that a bond $(x_p, x_{p+1})$ of a path $\gamma = (x_0, x_1, \ldots, x_n)$ is critical if $G_N(x_p, x_{p+1}) = \min_{0 \leq i < n} G_N(x_i, x_{i+1}) = G_N(\gamma)$.

Note that for every disjoint sets $A, B, C$,

$$G_N(A, B \cup C) = \max \{ G_N(A,B), G_N(A, C) \}. \quad \text{(4.2)}$$

Indeed, the left hand side is greater or equal than the right hand side because $G_N(A, D) \leq G_N(A, D')$ if $D \subset D'$. On the other hand, there exists a self-avoiding path $\gamma = (x_0, \ldots, x_n)$ from $A$ to $B \cup C$ such that $G_N(A, B \cup C) = G_N(\gamma)$. We may assume without loss of generality that $x_n$ belongs to $B$. Hence, $\gamma$ is a self-avoiding path from $A$ to $B$ and $G_N(\gamma) \leq G_N(A,B)$, which proves (4.2).

Lemma 4.1. Fix $A$, $B \subset E$ such that $A \cap B = \emptyset$. The capacity $\text{cap}_N(A, B)$ is of the same magnitude of $G_N(A, B)$. There exists a positive and finite constant $C_1$, depending only on $E$ and on the limiting rates $r(x,y)$, such that

$$C_1^{-1} \leq \frac{\text{cap}_N(A, B)}{G_N(A, B)} \leq C_1$$

for all $N$ sufficiently large.

Proof. Fix two subsets $A$, $B$ of $E$ such that $A \cap B = \emptyset$. We shall obtain an upper and a lower bound for $\text{cap}_N(A,B)$. We start with a lower bound. Fix a self-avoiding path $\gamma = (x_0, x_1, \ldots, x_n)$ in $\Gamma_{A,B}$ such that $G_N(A, B) = \min_{0 \leq i < n} G_N(x_i, x_{i+1})$. This path always exists because the number of paths is finite. For any function $f : E \to \mathbb{R}$,

$$D_N(f) \geq \sum_{i=0}^{n-1} G_N(x_i, x_{i+1}) |f(x_{i+1}) - f(x_i)|^2.$$
Therefore, minimizing over all \( f : E \to \mathbb{R} \) such that \( f(x) = 1, \ x \in A, \ f(y) = 0, \ y \in B \), we get that \( \text{cap}_N(A, B) \) is bounded below by

\[
\inf f \sum_{i=0}^{n-1} G_N(x_i, x_{i+1})[f(x_{i+1}) - f(x_i)]^2,
\]

where the infimum is carried over all functions \( f : \{x_0, \ldots, x_n\} \to \mathbb{R} \) such that \( f(x_0) = 1, f(x_n) = 0 \). A simple computation shows that this expression is equal to

\[
\left\{ \frac{1}{\sum_{i=0}^{n-1} G_N(x_i, x_{i+1})} \right\}^{-1},
\]

which is bounded below, for \( N \) large, by \( C_1 \min_{0 \leq i < n} G_N(x_i, x_{i+1}) \) for some positive constant \( C_1 \) depending only on \( E \) and the asymptotic rates \( r(x, y) \). By the definition of the path \( \gamma = (x_0, x_1, \ldots, x_n) \), \( \min_{0 \leq i < n} G_N(x_i, x_{i+1}) = G_N(A, B) \), which proves the lower bound for the capacity.

We now turn to the upper bound. Denote by \( \mathcal{B}_N \) the set of bonds \( (x, y) \) such that \( G_N(x, y) > G_N(A, B) \). The state space \( E \) can be written as the disjoint union of maximal connected components. More precisely, there exist disjoint subsets \( A_1, \ldots, A_m \) of \( E \), possibly singletons, fulfilling the next three conditions:

- \( E = \cup_{1 \leq j \leq m} A_j \);
- for any \( x, y \in A_j \), there exists a path \( \gamma = (x = x_0, x_1, \ldots, x_p = y) \) such that \( G_N(x_i, x_{i+1}) > G_N(A, B) \) for all \( 0 \leq i < p \);
- for any \( x \in A_j, y \in A_k, j \neq k \), there does not exist a path \( \gamma = (x = x_0, x_1, \ldots, x_p = y) \) such that \( G_N(x_i, x_{i+1}) > G_N(A, B) \) for all \( 0 \leq i < p \).

Note that if \( A_j \cap A \neq \emptyset \) then \( A_j \cap B = \emptyset \). Otherwise, there would be a self-avoiding path \( (x_0, x_1, \ldots, x_n) \) from \( A \) to \( B \) such that \( G_N(x_i, x_{i+1}) > G_N(A, B) \) for all \( 0 \leq i < n \), in contradiction with the definition of \( G_N(A, B) \).

Consider a self-avoiding path \( \gamma = (x_0, x_1, \ldots, x_n) \) in \( \Gamma_{A,B} \) such that \( G_N(A, B) = \min_{0 \leq i < n} G_N(x_i, x_{i+1}) \). The path \( \gamma \) may have bonds \( (x_i, x_{i+1}) \) in \( \mathcal{B}_N \). We claim, however, that there exists a bond \( (x_q, x_{q+1}) \) in \( \gamma \) such that \( G_N(x_q, x_{q+1}) = G_N(A, B) \) and such that there is no maximal connected component \( A_j \) of \( E \) such that

\[
A_j \cap [A \cup \{x_0, \ldots, x_q\}] \neq \emptyset \text{ and } A_j \cap [B \cup \{x_{q+1}, \ldots, x_n\}] \neq \emptyset . \tag{4.3}
\]

To prove this claim, let \( L \geq 1 \) be the number of critical bonds in \( \gamma \) and fix a critical bond \( (x_p, x_{p+1}) \) for which \( \{L\} \) does not hold. There exists therefore a maximal connected component \( A_j \) of \( E \) such that \( A_j \cap [A \cup \{x_0, \ldots, x_p\}] \neq \emptyset \) and \( A_j \cap [B \cup \{x_{p+1}, \ldots, x_n\}] \neq \emptyset \). By overlapping the bond \( (x_p, x_{p+1}) \) by a path in \( A_j \), we construct a new self-avoiding path \( \gamma' = (x_0', \ldots, x_n') \) from \( A \) to \( B \) with possibly different initial or final point which avoids the bond \( (x_p, x_{p+1}) \).

Since all bonds which belong to \( \gamma' \) and not to \( \gamma \) are in \( \mathcal{B}_N \) and since \( G_N(x_i, x_{i+1}) \geq G_N(x_p, x_{p+1}) = G_N(A, B), 0 \leq i < n \), \( G_N(x_i', x_{i+1}') \geq G_N(A, B) \) for all \( 0 \leq i < n' \). On the other hand, since \( \gamma' \) is a self-avoiding path from \( A \) to \( B \), \( \min_{0 \leq i < n'} G_N(x_i', x_{i+1}') \leq G_N(A, B) \). Hence, \( \min_{0 \leq i < n'} G_N(x_i', x_{i+1}') = G_N(A, B) \).

On the other hand, since all bonds which belong to \( \gamma' \) and not to \( \gamma \) are in \( \mathcal{B}_N \) and since \( (x_p, x_{p+1}) \) does not belong \( \gamma' \), the number of critical bonds of \( \gamma' \) is at most \( L - 1 \). It might be smaller than \( L - 1 \) if the set \( A_j \) overlaps more than one critical bond of \( \gamma \).

If the new path \( \gamma' \) fulfills condition \( \{L\} \), the claim is proved. If it does not, we apply the algorithm again. Since the algorithm reduces the number of critical
bonds by at least one, after a finite number of iterations we obtain a path satisfying (4.3) as claimed.

We now define a function $f$ equal to 1 on the set $A$, equal to 0 on the set $B$ and we show that the Dirichlet form of $f$ is bounded by $C_1G_N(A,B)$ for some finite constant $C_1$ which depends only on $E$. Let $(x_p, x_{p+1})$ be a critical bond of a path $\gamma = (x_0, \ldots, x_n)$ satisfying condition (4.3). Define $f : E \to \mathbb{R}$ as follows. Let $f(x) = 1$ for $x \in A$, $f(y) = 0$, $y \in B$. Define $f$ on $\gamma$ as $f(x_i) = 1$, $0 \leq i \leq p$, $f(x_j) = 0$, $p + 1 \leq i \leq n$. On each maximal connected component $A_j$ which intersects $A \cup \{x_0, \ldots, x_p\}$, set $f = 1$. Similarly, on each maximal connected component $A_k$ which intersects $\{x_{p+1}, \ldots, x_n\} \cup B$ set $f = 0$. Property (4.3) ensures that this can be done. On the remaining sites we define $f$ to be a fixed arbitrary constant $\omega$. Note that with this definition $f$ is constant on each maximal connected component $A_k$.

It remains to examine the Dirichlet form of $f$. There are three types of nonvanishing terms in this Dirichlet form. The first one is $G_N(x_p, x_{p+1}) = G_N(A,B)$. The second and third types are expressions of the form $G_N(x,y)(1-\omega)^2$, $G_N(x,y)\omega^2$, where $(x, y)$ does not belong to $\mathcal{B}_N$. In particular, the contribution to the Dirichlet form of $f$ of these expressions is bounded by $C_1G_N(A,B)\{\omega^2 + (1-\omega)^2\}$ for some finite constant which depends only on $E$. This proves that $D_N(f) \leq C_1G_N(A,B)$. Since $f$ is equal to 1 on the set $A$ and is equal to 0 on the set $B$, $\text{cap}_N(A,B) \leq C_1G_N(A,B)$, which proves the lemma.

This lemma presents a typical estimation of asymptotic capacities. We first obtain a lower bound of the Dirichlet form, uniform over all functions $f$, by disregarding some bonds. Then, we prove an upper bound for a specific candidate, believed to be close to the optimal function in view of the proof of the lower bound. This time, however, no bond can be neglected in the Dirichlet form.

Of course, the function $f$ proposed in the proof of the previous lemma gives only the correct magnitude of the capacity $\text{cap}_N(A,B)$ and not its exact asymptotic value. The computation of the exact asymptotic value requires a detailed information of the jump rates and has to be done model by model.

We may prove, however, that under certain assumptions the capacity between two sets conveniently rescaled converges. Fix two disjoint subsets of $E$: $A, B \subset E$, $A \cap B = \emptyset$. By definition, $G_N(A,B) = G_N(x,y)$ for some $x, y \in E$. By (2.5), $G_N(x,y) = g_N(x,y)G_N(j)$ for some $0 \leq j \leq 1$. Let $g_N(A,B) = G_N(j) \leq 1$ so that $G_N(A,B) / g_N(A,B)$ converges, as $N \to \infty$, to some number in $(0, \infty)$.

**Lemma 4.2.** Fix two disjoint subsets of $E$: $A, B \subset E$, $A \cap B = \emptyset$. Let $f_N : E \to [0,1]$ be the function $f_N(x) = P^N_x[T_A < T_B]$. Assume that $f_N$ converges pointwise to some function $f$. Denote by $\mathcal{B}(A,B)$ the set of pairs $\{x, y\}$ such that $G_N(x,y) \approx g_N(A,B)$. Then, $f(y) = f(x)$ if $G_N(x,y) \approx g_N(A,B)$ and

$$\lim_{N \to \infty} \frac{\text{cap}_N(A,B)}{g_N(A,B)} = \sum_{\{x,y\} \in \mathcal{B}(A,B)} g(x,y)[f(y) - f(x)]^2 \in (0, \infty) ,$$

where $g(x,y)$ has been introduced in (2.5).

**Proof.** Fix two disjoint subsets of $E$: $A, B \subset E$, $A \cap B = \emptyset$ and let $f_N : E \to [0,1]$ be the function $f_N(x) = P^N_x[T_A < T_B]$. It is well known that

$$\text{cap}_N(A,B) = D_N(f_N) = \sum_{\{x,y\} \in E} G_N(x,y)[f_N(y) - f_N(x)]^2 .$$

We first show that \( f(y) = f(x) \) if \( G_N(x, y) \succ g_N(A, B) \). Indeed, fix such a pair and note that
\[
G_N(x, y) | f_N(y) - f_N(x) |^2 \leq \text{cap}_N(A, B) .
\]
By Lemma 4.1, the right hand side is bounded above by \( C_1 \text{cap}_N(A, B) \) for some finite constant \( C_1 \) independent of \( N \). Since \( f_N \) converges to \( f \) pointwise and since \( G_N(x, y) \succ g_N(A, B) \), \( f(y) = f(x) \), proving the claim.

Let \( \mathcal{B} = \mathcal{B}(A, B) \). To prove a lower bound for the capacity, note that
\[
\text{cap}_N(A, B) \geq \sum_{\{x, y\} \in \mathcal{B}} G_N(x, y) | f_N(y) - f_N(x) |^2 .
\]
In view of (2.5), as \( N \uparrow \infty \) the right hand side divided by \( g_N(A, B) \) converges to
\[
\sum_{\{x, y\} \in \mathcal{B}} g(x, y) | f(y) - f(x) |^2 .
\]
To prove the upper bound, recall the variational formula (4.1) for the capacity to write
\[
\text{cap}_N(A, B) \leq \sum_{\{x, y\} \in E} G_N(x, y) | f(y) - f(x) |^2 .
\]
Since \( f(y) = f(x) \) if \( G_N(x, y) \succ g_N(A, B) \), and since \( f \) is absolutely bounded by 1, we may restrict the sum to the pairs \( (x, y) \) in \( \mathcal{B}(A, B) \). Hence,
\[
\limsup_{N \to \infty} \frac{\text{cap}_N(A, B)}{g_N(A, B)} \leq \sum_{\{x, y\} \in \mathcal{B}} g(x, y) | f(y) - f(x) |^2 ,
\]
which proves the second assertion of the lemma. Moreover, by Lemma 4.1 and since \( G_N(A, B) \approx g_N(A, B) \), the limit belongs to \( (0, \infty) \). \qed

This result shows that the sequence of capacities are comparable if the sequence of hitting functions \( f_{A, B}^N(x) = \mathbb{P}_x^N[T_A < T_B] \) converge. This remark highlights the interest of the next result. Recall that we denote by \( R_N^F(x, y) \), \( x, y \in F \), the jump rates of the trace process \( \{\eta^F : t \geq 0\} \), \( F \subset E \).

**Lemma 4.3.** For every subset \( F \) of \( E \), the sequences \( \{R_N^F(x, y) : N \geq 1\} \), \( x \neq y \in F \), are comparable. Moreover, for every subsets \( A, B \) of \( E \), \( A \cap B = \emptyset \), and for every \( x \in E \), the following limits exist
\[
f_{A, B}(x) := \lim_{N \to \infty} \mathbb{P}_x^N[T_A < T_B] .
\]

**Proof.** It follows from the displayed formula presented just after Corollary 6.2 in [2] that
\[
R_N^F(x, y) = \frac{\sum_{z \in E} R_N(x, y) R_N(w, z) + R_N(x, w) R_N(w, y)}{\sum_{z \in E} R_N(w, z)}
\]
if \( F = E \setminus \{w\} \). Iterating this formula, we may show that for every proper subset \( F \) of \( E \), \( R_N^F(x, y) \) may be expressed as a ratio of sums of products of the rates \( R_N(\cdot, \cdot) \). The sum in the numerator contains only products with the same number of terms and the same thing happens in the denominator. In particular, by assumption (2.2), the sequences \( \{R_N^F(x, y) : N \geq 1\} \), \( x \neq y \in F \), are comparable. This proves the first assertion of the lemma.
If we denote by \( p_N^F(x, y) \) the jump probabilities associated to the rates \( R_N^F(x, y) \),

\[
p_N^F(x, y) = \frac{R_N^F(x, y)}{\sum_{z \in F} R_N^F(x, z)}; \quad x \neq y \in F,
\]

\( p_N^F(x, y) \) converges to some \( p^F(x, y) \) as \( N \to \infty \).

Denote by \( P_N^{X,F}, x \in F \), the probability on the path space \( D(\mathbb{R}_+, F) \) induced by the trace process \{\( \eta^F_t : t \geq 0 \)\} starting from \( x \). Clearly, \( P_N^{X,F}[T_A < T_B] = P_N^{X,F}[\eta^F_1 \in A, \eta^F_2 \in B] \), for \( F = \{x\} \cup A \cup B \). If \( x \) does not belong to \( A \cup B \), last probability is equal to \( \sum_{y \in A} p_N^F(x, y) \) and we proved that this expression converges as \( N \to \infty \). \( \square \)

**Corollary 4.4.** For every subset \( F \) of \( E \) and every subsets \( A, B \) of \( F \), \( A \cap B = \emptyset \), the ratio of mean rates

\[
\frac{r_N^F(A, B)}{r_N^F(A, F \setminus A)} = \frac{\sum_{x \in A} \sum_{y \in B} \mu^N(x) R_N^F(x, y)}{\sum_{x \in A} \sum_{z \in F \setminus A} \mu^N(x) R_N^F(x, z)}
\]

converges to some number \( p_F(A, B) \in [0, 1] \) as \( N \to \infty \).

**Proof.** It follows from the explicit formula for the rates \( R_N^F \), derived in the proof of the previous lemma, from equation (2.3) and from assumption (2.2) that the sequences \( (\mu^N(x) R_N^F(x, y) : N \geq 1) \), \( x \neq y \in F \), are comparable. The result is a simple consequence of this observation. \( \square \)

5. **The shallowest valleys**

Recall the definition of a valley with an attractor introduced in [1]. To avoid long sentences, in this article we call a valley with an attractor simply a valley. We describe in this section the shallowest valleys and we show that their depths are comparable.

We shall say that there exists an open path from \( x \) to \( y \) if there exists a sequence \( x = x_0, x_1, \ldots, x_n = y \) such that \( R_N(x_i, x_{i+1}) \approx 1 \), \( 0 \leq i < n \). Two sites \( x \neq y \) are said to be equivalent, \( x \sim y \), if there exist an open path from \( x \) to \( y \) and an open path from \( y \) to \( x \). If we also declare any site to be equivalent to itself, \( \sim \) is an equivalent relation. We denote by \( C_1, C_2, \ldots, C_\alpha \) the equivalent classes.

Some equivalent classes are connected to other equivalent classes by open paths. By drawing an arrow from a set \( C_i \) to a set \( C_j \) if there exist \( x \in C_i, y \in C_j \) such that \( R_N(x, y) \approx 1 \), the set \( \{C_1, \ldots, C_\alpha\} \) becomes an oriented graph with no directed loops. We denote by \( \mathcal{E}_1, \mathcal{E}_2, \ldots, \mathcal{E}_\nu \) the leaves of this graph, in the terminology of graph theory, the equivalent classes with no successors. Denote by \( \Delta \) the union of the remaining sets so that \( \{\mathcal{E}_1, \ldots, \mathcal{E}_\nu, \Delta\} \) forms a partition of \( E \):

\[
E = \mathcal{E} \cup \Delta, \quad \mathcal{E} = \mathcal{E}_1 \cup \cdots \cup \mathcal{E}_\nu.
\]

(5.1)

For \( 1 \leq i \leq \nu \), let \( \tilde{\mathcal{E}}_i \) be the union of all leaves except \( \mathcal{E}_i \):

\[
\tilde{\mathcal{E}}_i = \bigcup_{j \neq i} \mathcal{E}_j.
\]

By construction, all sites in an equivalent class \( C_j \) have probability of the same magnitude: there exists a finite, positive constant \( C_0 \) such that for all \( 1 \leq j \leq \alpha \),

\[
C_0^{-1} \leq \frac{\mu_N(x)}{\mu_N(y)} \leq C_0, \quad x, y \in C_j.
\]

(5.2)

We may also estimate the capacity between two states in a leave \( \mathcal{E}_i \).
Lemma 5.1. Fix $1 \leq i \leq \nu$. There exists a finite constant $C_1$, which depends only on $E$, such that for any $x \neq y$ in $\mathcal{E}_i$,
\[
C_1^{-1} \leq \frac{\text{cap}_N(\{x\}, \{y\})}{\mu_N(\mathcal{E}_i)} \leq C_1.
\]

Proof. Fix $1 \leq i \leq \nu$ and $x \neq y$ in $\mathcal{E}_i$. Consider a function $f : E \to \mathbb{R}$ such that $f(x) = 1$, $f(y) = 0$ and fix a self-avoiding open path $\gamma = (x = x_0, \ldots, x_n = y)$ from $x$ to $y$. By Schwarz inequality,
\[
1 = |f(y) - f(x)|^2 = \left\{ \sum_{i=0}^{n-1} (f(x_{i+1}) - f(x_i)) \right\}^2 \leq \sum_{i=0}^{n-1} \mu_N(x_i) R_N(x_i, x_{i+1}) \{f(x_{i+1}) - f(x_i)\}^2 \sum_{i=0}^{n-1} \frac{1}{\mu_N(x_i) R_N(x_i, x_{i+1})}.
\]
Therefore, $D_N(f)$, is bounded below by
\[
\sum_{i=0}^{n-1} \mu_N(x_i) R_N(x_i, x_{i+1}) \{f(x_{i+1}) - f(x_i)\}^2 \geq \left\{ \sum_{i=0}^{n-1} \frac{1}{\mu_N(x_i) R_N(x_i, x_{i+1})} \right\}^{-1}.
\]
Since $\gamma$ is an open path, $R_N(x_i, x_{i+1})$ is of order one. Hence, by [5.2], there exists a constant $C_1$ which depends only on $E$ such that for any function $f : E \to \mathbb{R}$ such that $f(x) = 1$, $f(y) = 0$, $D_N(f) \geq C_1^{-1} \mu_N(\mathcal{E}_i)$. This proves that $\text{cap}_N(\{x\}, \{y\}) \geq C_1^{-1} \mu_N(\mathcal{E}_i).

To prove the reverse inequality, consider the function $f_* : E \to \mathbb{R}$ which is equal to 1 at $x$ and is 0 elsewhere. Clearly,
\[
D_N(f_*) = \mu_N(x) \sum_{z \neq x} R_N(x, z).
\]
By hypothesis, $R_N(x, z) \leq C_0$ so that $D_N(f_*) \leq C_0 \mu_N(\mathcal{E}_i)$, proving the lemma. \qed

Recall Theorem 2.6 of [1] which presents sufficient conditions for a triple to be a valley in the context of reversible Markov processes.

Fix a leave $\mathcal{E}_i, 1 \leq i \leq \nu$, and a site $x$ in $\mathcal{E}_i$. Denote by $\mathcal{E}_i$ the set $\mathcal{E}_i$ as well as the constant sequence of sets $(\mathcal{E}_i, \mathcal{E}_i, \ldots)$ and by $x$ not only the site $x$ but also the constant sequence equal to $x$. This convention is used from now on without further notice. Denote by $\mathcal{B}_i$ the set of sites in $\Delta$ of measure of lower magnitude than $\mathcal{E}_i$: $\mathcal{B}_i = \{ y \in \Delta : \mu_N(y) < \mu_N(\mathcal{E}_i) \}$. Note that $\mathcal{B}_i$ is the union of some equivalence classes.

Lemma 5.2. Fix $1 \leq i \leq \nu$ and $x$ in $\mathcal{E}_i$. The triple $(\mathcal{E}_i, \mathcal{E}_i \cup \mathcal{B}_i, x)$ is a valley of depth $\theta_{N,i} := \mu_N(\mathcal{E}_i)/\text{cap}_N(\mathcal{E}_i, [\mathcal{E}_i \cup \mathcal{B}_i])$.

Proof. By [1] Theorem 2.6], to show that $(\mathcal{E}_i, \mathcal{B}_i \cup \mathcal{E}_i, x)$ is a valley of depth $\mu_N(\mathcal{E}_i)/\text{cap}_N(\mathcal{E}_i, [\mathcal{E}_i \cup \mathcal{B}_i])$ we need to check that $\mu_N(\mathcal{B}_i)/\mu_N(\mathcal{E}_i)$ vanishes as $N \uparrow \infty$ and that
\[
\lim_{N \to \infty} \frac{\text{cap}_N(\mathcal{E}_i, [\mathcal{B}_i \cup \mathcal{E}_i])}{\text{cap}_N(x)} = 0,
\]
where $\text{cap}_N(x) = \min_{y \in \mathcal{E}_i} \text{cap}_N(\{x\}, \{y\})$. The first condition follows from the definition of the set $\mathcal{B}_i$. The second one is simple to check. Fix a positive function $f : E \to \mathbb{R}$ bounded by one and constant in $\mathcal{E}_i$ and in $[\mathcal{B}_i \cup \mathcal{E}_i]$. In the expression of
the Dirichlet form $D_N(f) = \sum_{y,z} G_N(y, z)[f(z) - f(y)]^2$, there are two types of non-vanishing terms. Either $y$ belongs to $\mathcal{E}$, and we may estimate $G_N(y, z)[f(z) - f(y)]^2$ by $\mu_N(\mathcal{E}) \max_{y \in \mathcal{E}, z \notin \mathcal{E}} R_N(y, z)$ or $y$ does not belong to $\mathcal{E}$ and we may estimate $G_N(y, z)[f(z) - f(y)]^2$ by $\mu_N(B_i)$ because $R_N(y, z) \leq C_0$. Both expressions are of an order much smaller than the one of $\mu_N(\mathcal{E})$ because $\mathcal{E}$ has no successors. Therefore, (5.3) follows from Lemma 5.4, proving that $(\mathcal{E}_i, B_i \cup \mathcal{E}_i, x)$ is a valley.

Next lemma shows that a leaf is attained from any site in a time scale of magnitude one. Recall that $T_A, A \subset E$, stands for the hitting time of $A$.

**Lemma 5.3.** There exists a finite constant $C_0$, independent of $N$, such that

$$\max_{x \in \Delta} \mathbf{E}_x^N[T_E] \leq C_0.$$

**Proof.** Denote by $\{\tau_j : j \geq 0\}$ the jump times of the Markov process $\{\eta_t^N : t \geq 0\}$:

$$\tau_0 = 0, \quad \tau_{j+1} = \inf\{t > \tau_j : \eta_t^N \neq \eta_j^N\}, \quad j \geq 0.$$

Denote by $\{Y_k^N : k \geq 0\}$ the jump chain associated to the Markov process $\{\eta_t^N : t \geq 0\}$, i.e., the discrete time Markov chain formed by the successive sites visited by $\eta_t^N$:

$$Y_k^N = \eta_{\tau_k}^N, \quad k \geq 0.$$

For each site $x$ in $\Delta$, there exists an open path $\gamma = (x = x_0, x_1, \ldots, x_{n(x)})$ such that $x_{n(x)} \in \mathcal{E}$, $R_N(x_i, x_{i+1}) > C_0$, $0 \leq i < n(x)$, for some positive constant $C_0$, independent of $N$, whose value may change from line to line. In particular,

$$P_x^N[Y_k^N = x_k : 0 \leq k \leq n(x)] \geq C_0.$$ (5.4)

Let $n = \max\{n(x) : x \in \Delta\}$.

By the strong Markov property and decomposing the space according to the partition $\{T_E \leq \tau_n\}, \{T_E > \tau_n\}$, for every $x \in \Delta$, since on the set $\{T_E > \tau_n\}$,

$$T_E = \tau_n + T_E \circ \tau_n,$$

$$\mathbf{E}_x^N[T_E] = \mathbf{E}_x^N[\min\{T_E, \tau_n\}] + \mathbf{E}_x^N[1\{T_E > \tau_n\}\mathbf{E}_{\eta_{\tau_n}^N}[T_E]].$$

As $\eta_{\tau_n}^N$ belongs to $\Delta$ when $T_E > \tau_n$, it follows from the previous identity that

$$\max_{x \in \Delta} \mathbf{E}_x^N[T_E] \leq \frac{\max_{x \in \Delta} \mathbf{E}_x^N[\min\{T_E, \tau_n\}]}{1 - \mathbf{P}_x^N[\tau_n \leq T_E]}. $$

It follows from (5.3) that the denominator is bounded below by a strictly positive constant $C_0$. To estimate the numerator, observe that $T_E = \sum_{j \geq 1} \tau_j \mathbf{1}\{A_j\}$, where $A_j = \{Y_0^N \in \Delta, \ldots, Y_{j-1}^N \in \Delta, Y_j^N \in \mathcal{E}\}$. Hence, $\min\{T_E, \tau_n\} = \sum_{1 \leq j < n} \tau_j \mathbf{1}\{A_j\} + \tau_n \mathbf{1}\{B_n\}$, where $B_n = \cup_{j \geq n} A_j$. Since on the set $A_j, Y_k^N \in \Delta$, $0 \leq k < j$, on $A_j$ the random time $\tau_j$ can be estimated by the sum of $j$ mean $C_0$ independent exponential random variables. Hence,

$$\max_{x \in \Delta} \mathbf{E}_x^N[\min\{T_E, \tau_n\}] \leq C_0 \sum_{j=1}^n j,$$

which concludes the proof of the lemma. □

A similar argument permits to increase the negligible set $B_i$ of the valley $(\mathcal{E}_i, \mathcal{E}_i \cup B_i, x)$. 

Lemma 5.4. Fix $1 \leq i \leq \nu$ and $x$ in $\mathcal{E}_i$. The triple $(\mathcal{E}_i, \mathcal{E}_i \cup \Delta, x)$ is a valley of depth $\theta_{N,i} = \mu_N(\mathcal{E}_i)/\cap_N(\mathcal{E}_i, [\mathcal{E}_i \cup \mathcal{B}_i]^c)$. Moreover, $\cap_N(\mathcal{E}_i, [\mathcal{E}_i \cup \mathcal{B}_i]^c) \approx \cap_N(\mathcal{E}_i, \check{\mathcal{E}_i})$.

Proof. Fix $1 \leq i \leq \nu$ and $x$ in $\mathcal{E}_i$. By Lemmas [5.2] and [10.1] to prove the first claim of the proposition we need to show that for every $\delta > 0$

$$\lim_{N \to \infty} \max_{y \in \Delta \setminus \mathcal{B}_i} \mathbf{P}_y^N [T_{\check{\mathcal{E}_i}} > \delta \theta_{N,i}] = 0.$$ 

Fix $y$ in $\Delta \setminus \mathcal{B}_i$. By definition, $\mu_N(y) \geq \mu_N(\mathcal{E}_i)$. In particular, there is no open path from $y$ to $\mathcal{E}_i$. Indeed, if $y = y_0, \ldots, y_{n-1} \notin \mathcal{E}_i$, $y_n \in \mathcal{E}_i$ is an open path from $y$ to $\mathcal{E}_i$, the relation $\mu_N(y_{n-1}) \geq \mu_N(y)$ contradicts the identity $\mu_N(y_{n-1}) R_N(y_{n-1}, y_n) = \mu_N(y_n) R_N(y_n, y_{n-1})$ because $\max_{z \in \mathcal{E}_i, z' \notin \mathcal{E}_i} R_N(z, z') < 1$.

Recall that we denote by $\{Y^N_k : k \geq 0\}$ the jump chain associated to the Markov process $\eta^N$. Its jump probabilities $p_N(x, y)$, $x, y \in E$, $x \neq y$, are given by

$$p_N(x, y) = \frac{R_N(x, y)}{\sum_{z \in E} R_N(x, z)}.$$

In view of (2.1), as $N \uparrow \infty$, $p_N(x, y)$ converges to some $p(x, y) \in [0, 1]$ such that $\sum_y p(x, y) = 1$. Let $\{Z_k : k \geq 0\}$ be the discrete time Markov chain associated to the jump probabilities $p(x, y)$. Note that the Markov chain $Z_k$ may not be irreducible.

Clearly, we may couple both chains in a way that for every $n \geq 1$

$$\lim_{N \to \infty} \mathbf{P}_y^N \left[ \bigcup_{k=1}^n \{Y^N_k \neq Z_k\} \right] = 0. \quad (5.5)$$

On the other hand, before reaching $\mathcal{E}$ the Markov chain $Z_k$ only uses open bonds. Since there is no open path from $y$ to $\mathcal{E}_i$ and since there are open paths from $y$ to $\check{\mathcal{E}_i}$, the chain $Z_k$ eventually reaches $\check{\mathcal{E}_i}$. Hence,

$$\lim_{n \to \infty} \mathbf{P}_y^N \left[ \bigcap_{k=1}^n \{Z_k \notin \check{\mathcal{E}_i}\} \right] = 0.$$

Recall that $\{\tau_n : n \geq 1\}$ stands for the jump times of the Markov process $\eta^N$. On the set $[\cap_{k=1}^n \{Y^N_k = Z_k\}] \cap [\cup_{k=1}^n \{Z_k \in \check{\mathcal{E}_i}\}]$, $T_{\check{\mathcal{E}_i}} \leq \tau_k$ for some $k \leq n$, and $\tau_k$ may be bounded by the sum of $k$ mean $C_0$ i.i.d. exponential random variables, for some finite constant $C_0$, independent of $N$. Therefore, since $\theta_{N,i} > 1$, for every $n \geq 1$,

$$\lim_{N \to \infty} \mathbf{P}_y^N \left[ T_{\check{\mathcal{E}_i}} > \delta \theta_{N,i}, \bigcap_{k=1}^n \{Y^N_k = Z_k\}, \bigcup_{k=1}^n \{Z_k \in \check{\mathcal{E}_i}\} \right] = 0,$$

which proves the first assertion of the lemma.

In view of Lemma [4.1], to prove the second claim, it is enough to show that $G_N(\mathcal{E}_i, [\mathcal{E}_i \cup \mathcal{B}_i]^c) \approx G_N(\mathcal{E}_i, \check{\mathcal{E}_i})$. In fact, we assert that

$$G_N(\mathcal{E}_i, [\mathcal{E}_i \cup \mathcal{B}_i]^c) = G_N(\mathcal{E}_i, \check{\mathcal{E}_i}) \quad (5.6)$$

for all $N$ sufficiently large.

On the one hand, since $\check{\mathcal{E}_i} \subset [\mathcal{E}_i \cup \mathcal{B}_i]^c$, $G_N(\mathcal{E}_i, \check{\mathcal{E}_i}) \leq G_N(\mathcal{E}_i, [\mathcal{E}_i \cup \mathcal{B}_i]^c)$. On the other hand, since the set $E$ is finite, there exists a path $\gamma = (x_0, \ldots, x_n)$ in
estimate holds for \( \mu \) because 
\[ R \]
dechange from line to line. Since 
\[ E \]
and we may assume without loss of generality that 
\[ x \]
may not belong to 
\[ E \]
and we may assume without loss of generality that 
\[ x \]
and 
\[ 0 \]

Clearly, for every 
\[ x \]
which proves the first assertion of the lemma. The second one follows from the
\[ \text{(5.5)} \]
juxtaposing the paths 
\[ \gamma \] \text{and} \( \tilde{\gamma} \), in view of
\[ \text{(5.7)} \]
we obtain a self-avoiding path from \( E \) to \( \tilde{E} \) such that 
\[ \min_{1 \leq i < l} G_N(x_i, x_{i+1}) = \min_{1 \leq i < l} G_N(x_i, x_{i+1}) = G_N(\tilde{E}_i, [\tilde{E}_i \cup B_i]) \] for \( N \) sufficiently large. Hence, also in the case where \( x_n \) belongs to \( \Delta \setminus B_i \), 
\[ G_N(\tilde{E}_i, \tilde{E}_j) \geq G_N(\tilde{E}_i, [\tilde{E}_i \cup B_i]) \], which proves
\[ \text{(5.6)} \]

We may in fact compute the asymptotic behavior of the depth \( \theta_{N,i} \) of the valley
\[ (E_i, \tilde{E}_i \cup \Delta, x) \] with the help of Lemma 4.2. Recall the definition of the Markov chain
\[ \{Z_k : k \geq 0\} \] introduced in the previous proposition. Denote by \( P^x_\Delta \) the probability on the path space \( D(\mathbb{Z}^+, E) \) induced by the Markov chain \( \{Z_k : k \geq 0\} \) starting from \( x \).

**Lemma 5.5.** Fix a subset \( I \) of \( \{1, \ldots, v\} \) and let \( J = \{1, \ldots, v\} \setminus I \), \( f_N(x) = P^x_N[T_{E_i} < T_{\tilde{E}_j}] \), where \( E_i = \cup_{i \in I} E_i \). We claim that
\[ \lim_{N \to \infty} P^x_N[T_{E_i} < T_{\tilde{E}_j}] = f_{I,J}(x) := P^x_\Delta[T_{E_i} < T_{\tilde{E}_j}] , \quad x \in E . \]
In particular,
\[ \lim_{N \to \infty} \frac{\text{cap} P^x_N(\tilde{E}_i, \tilde{E}_j)}{\text{cap} P^x_N(\tilde{E}_i, \tilde{E}_j)} = \sum_{(x,y) \in \mathcal{G}(\tilde{E}_i, \tilde{E}_j)} g(x, y) [f_{I,J}(y) - f_{I,J}(x)]^2 \in (0, \infty) . \]

**Proof.** Clearly, for every \( x \in E \),
\[ \lim_{n \to \infty} P^x_\Delta \left[ \bigcup_{k=1}^{n} \{Z_k \in \tilde{E}_i \} \right] = 1 . \]
It follows from this estimates and from \( \text{(5.5)} \) that for every \( x \in \Delta \),
\[ \lim_{N \to \infty} P^x_N[T_{E_i} < T_{\tilde{E}_j}] = P^x_\Delta[T_{E_i} < T_{\tilde{E}_j}] , \]
which proves the first assertion of the lemma. The second one follows from the
\[ \text{previous result and Lemma 4.2} \]

Note that this result is a particular case of Lemma 4.3. The same argument provides the asymptotic value of the capacity between \( E_i \) and \( [\tilde{E}_i \cup B_i] \).
Lemma 5.6. Fix $1 \leq i \leq \nu$ and let $f_N : E \rightarrow [0, 1]$ be given by $f_N(x) = P^N_T |_{E_i} < T_{E_j \cup B_i}$. Then, $f_N$ converges pointwisely to $f(x) = P^Z_x |_{E_i} < T_{E_j \cup B_i}$. In particular,

$$
\lim_{N \rightarrow \infty} \frac{\text{cap}_N(E^i_i \cup B_i \cap E)}{\text{cap}_N(E^i_i)} = \sum_{(x,y) \in \mathcal{B}(E^i_i \cup B_i \cap E)} g(x,y) [f(y) - f(x)]^2.
$$

We may now state the first main result of this section.

Proposition 5.7. For $1 \leq i \leq \nu$, $(E_i, E_i \cup \Delta, x)$, $x \in E_i$, is a valley of depth $\theta_{N,i} = \mu_N(E_i)/\text{cap}_N(E_i, \tilde{E}_i)$. Moreover,

$$
\lim_{N \rightarrow \infty} \frac{\text{cap}_N(E_i, [E_i \cup B_i \cap E])}{\text{cap}_N(E_i, \tilde{E}_i)} = 1.
$$

Proof. Fix $1 \leq i \leq \nu$ and note that the set $E_j$ appearing in Lemma 5.6 is equal to $\tilde{E}_i$ if $I = \{ i \}$. By (5.5), $g_N(E_i, [E_i \cup B_i \cap E]) = g_N(E_i, \tilde{E}_i)$ so that $\mathcal{B}(E_i, [E_i \cup B_i \cap E]) = \mathcal{B}(E_i, \tilde{E}_i)$. Let $g_i = f_{i,j}$ when $I = \{ i \}$. Since there is an open path from any state in $\Delta \setminus B_i$ to $\tilde{E}_i$ and no open path from a state in $\Delta \setminus B_i$ to $E_i$, $f_i(x) = \sum_{k} g_k(x)$. This proves the corollary in view of Lemmas 5.5 and 5.6.

By Proposition 5.7 and Lemma 5.5,

$$
u_i := \lim_{N \rightarrow \infty} \frac{\text{cap}_N(E_i, \tilde{E}_i)}{\mu_N(E_i)} \in (0, \infty) . (5.8)
$$

In particular, the depths of the valleys are comparable.

Proposition 5.8. The sequences $(\theta_{N,i} : N \geq 1)$, $1 \leq i \leq \nu$, are comparable and $\theta_{N,i} \geq 1$, $1 \leq i \leq \nu$.

Proof. To prove this lemma, we have to show that, as $N \uparrow \infty$, the sequences $\mu_N(E_i)/\text{cap}_N(E_i, \tilde{E}_i)$, $i \neq j$, either vanish, diverge, or converge. Fix $i \neq j$. By (5.8),

$$
\lim_{N \rightarrow \infty} \frac{\mu_N(E_i)}{\text{cap}_N(E_i, \tilde{E}_i)} = \frac{\theta_{N,i}}{\theta_{N,j}} \lim_{N \rightarrow \infty} \frac{\mu_N(E_i)}{\text{cap}_N(E_i, \tilde{E}_i)} .
$$

By (5.2) and (2.4), $\mu_N(E_k) = \mu_N(x_k) a_N$ for some $x_k \in E_k$ and some sequence $a_N$ which converges to some $a \in (0, \infty)$ as $N \uparrow \infty$. On the other hand, by definition, $g_N(E_k, \tilde{E}_k) = G_N(y_k, z_k) b_N = \mu_N(y_k) R_N(y_k, z_k) b_N$ for some bond $(y_k, z_k)$, where $b_N$ converges to some limit $b \in (0, \infty)$ as $N \uparrow \infty$. Hence,

$$
\theta_{N,i} / \theta_{N,j} = c_N \frac{\mu_N(x_k) \mu_N(y_k) R_N(y_j, z_k)}{\mu_N(x) \mu_N(y) R_N(y, z)}
$$

for some sequence $c_N$ which converges to some limit $c \in (0, \infty)$ as $N \uparrow \infty$. In view of identity (2.3) and assumption (2.2), the sequences $\theta_{N,i}$ are comparable. This proves the first assertion of the lemma.

Fix $1 \leq i \leq \nu$ and recall the definition of $\theta_{N,i}$ given in Proposition 5.7. By Lemma 5.1 it is enough to show that $\mu_N(E_i)/G_N(E_i, \tilde{E}_i) > 1$. Fix a self-avoiding path $\gamma = (x_0, \ldots, x_n)$ from $E_i$ to $\tilde{E}_i$ such that $G_N(\gamma) = G_N(E_i, \tilde{E}_i)$. There exists a bond $(x_j, x_{j+1})$ such that $x_j \in E_i$, $x_{j+1} \notin E_i$. By definition of $G_N(\gamma)$, (5.2) and since $\tilde{E}_i$ is a leaf, $G_N(\gamma) \leq G_N(x_j, x_{j+1}) < \mu_N(x_j) \approx \mu_N(E_i)$, proving the second assertion of the lemma.

\[ \square \]
6. Metastability among the shallowest valleys

We describe in this section the asymptotic behavior of the Markov process \( \eta_t^N : t \geq 0 \) on the smallest time scale needed for the process to jump from one leave to another.

Let \( \theta_N(1) = \min \{ \theta_{N,i} : 1 \leq i \leq \nu \} \) and denote by \( S_1 \) the indices of the shallowest leaves, i.e., the ones whose valleys have depth of magnitude \( \theta_N(1) \):

\[
S_1 = \{ i : \theta_{N,i} \approx \theta_N(1) \}.
\]

Since, by Proposition 5.8, the depths of the valleys are comparable and since \( \theta_N(1) \) is the depth of the shallowest valley, \( \theta_N(1)/\theta_{N,i} \) converges as \( N \uparrow \infty \):

\[
\lambda(i) := \lim_{N \to \infty} \frac{\theta_N(1)}{\theta_{N,i}} \in (0, \infty) . \tag{6.1}
\]

**Lemma 6.1.** For any \( 1 \leq i \neq j \leq \nu \), \( \theta_N(1) r_N^e(\mathcal{E}_i, \mathcal{E}_j) \) converges, as \( N \uparrow \infty \), to some number \( r(i,j) \in [0,1] \).

**Proof.** Fix \( 1 \leq i \neq j \leq \nu \). By [1] Lemma 6.7 and by Proposition 5.4, we may rewrite \( \theta_N(1) r_N^e(\mathcal{E}_i, \mathcal{E}_j) \) as

\[
\theta_N(1) r_N^e(\mathcal{E}_i, \mathcal{E}_j) = \theta_N(1) \frac{\text{cap}_N(\mathcal{E}_i, \mathcal{E}_j)}{\mu_N(\mathcal{E}_i)} \frac{r_N^e(\mathcal{E}_i, \mathcal{E}_j)}{r_N^e(\mathcal{E}_i, \mathcal{E}_j)} = \frac{\theta_N(1)}{\theta_{N,i}} r_N^e(\mathcal{E}_i, \mathcal{E}_j).
\]

By (6.1), \( \theta_N(1)/\theta_{N,i} \) converges to \( \lambda(i) \). On the other hand, by Corollary 4.4, \( r_N^e(\mathcal{E}_i, \mathcal{E}_j)/r_N^e(\mathcal{E}_i, \mathcal{E}_j) \) converges, as \( N \uparrow \infty \), to some number \( q(i,j) \in [0,1] \). This proves the lemma with \( r(i,j) = \lambda(i) q(i,j) \).

Let \( \Psi : \mathcal{E} \to \{1, \ldots, \nu\} \) be given by \( \Psi(x) = \sum_{1 \leq i \leq \nu} i 1\{x \in \mathcal{E}_i\} \).

**Lemma 6.2.** Fix \( 1 \leq i \leq \nu \) and \( x \in \mathcal{E}_i \). Under \( \mathbf{P}_x^N \), the speeded up process \( X_t^N = \Psi(\eta_{t\theta_N(1)}^N) \) converges to a Markov process on \( \{1, \ldots, \nu\} \) with rates \( r(\cdot, \cdot) \) starting from \( i \).

**Proof.** We need to check that the assumptions of [1] Theorem 2.7] are fulfilled. On the one hand, condition (H1) follows from Lemma 5.1 and Proposition 5.8 which asserts that \( \theta_{N,i} \uparrow \infty \) as \( N \uparrow \infty \). On the other hand, condition (H0) has been proven in Lemma 6.1.

Note that \( \lambda(j) = 0 \) if \( j \not\in S_1 \). The points in \( S_1^c \) are therefore absorbing for the asymptotic dynamics.

Recall Definition 3.7 of [1]. The main result of this section, stated below in Proposition 6.3, asserts that the Markov process \( \{\eta_t^N : t \geq 0\} \) exhibits a metastable behavior on the time scale \( \theta_N(1) \) with asymptotic dynamics characterized by the jumps rates \( r(i,j) \) introduced in Lemma 6.1. Denote by \( \{\mathbb{P}_i : 1 \leq i \leq \nu\} \) the laws on the path space \( D(\mathbb{R}_+, \{1, \ldots, \nu\}) \) of a Markov process on \( \{1, \ldots, \nu\} \) whose sites in \( S_1^c \) are absorbing and which jumps from \( i \in S_1 \) to \( j \neq i \) at rate \( r(i,j) \).

**Proposition 6.3.** Fix a site \( x_i \) on each leave \( \mathcal{E}_i \). The sequence of Markov process \( \{\eta_t^N : t \geq 0\} \) exhibits a metastable behavior on the time scale \( \theta_N(1) \) with metastates \( \{\mathcal{E}_i : 1 \leq i \leq \nu\} \), metapoints \( \{x_i : 1 \leq i \leq \nu\} \) and asymptotic Markov dynamics \( \{\mathbb{P}_i : 1 \leq i \leq \nu\} \).
Proof. Condition (M2) has been proven in Lemma 6.2.
To prove (M3'), observe that for every $x \in E$,

$$E_{x}^{N} \left[ \int_{0}^{t} \mathbf{1}_{\{\eta_{\lambda t}^{N} \in \Delta \}} \, ds \right] \leq \max_{y \in \Delta} E_{y}^{N} \left[ \int_{0}^{t} \mathbf{1}_{\{\eta_{\lambda t}^{N} \in \Delta \}} \, ds \right].$$

Fix $y \in \Delta$ and denote by $U_{k}, V_{k}, k \geq 1$, the successive lengths of the sojourns in $\Delta$ and $\Delta^{c}$:

$$U_{1} = \inf \{t > 0 : \eta_{t}^{N} \not\in \Delta \} , \quad V_{1} = \inf \{t > 0 : \eta_{t}^{N} \in \Delta \} ,$$

$$U_{k+1} = \inf \{t > 0 : \eta_{t+U_{k}}^{N} \not\in \Delta \} , \quad V_{k+1} = \inf \{t > 0 : \eta_{t+U_{k+1}}^{N} \in \Delta \} .$$

Denote by $\{N_{t} : t \geq 0 \}$ the counting process associated to the sequence $\{V_{k} : k \geq 1 \}$:

$$\{N_{t} = k \} = \{V_{1} + \cdots + V_{k} \leq t < V_{1} + \cdots + V_{k+1} \} , \quad k \geq 0 ,$$

and observe that

$$\int_{0}^{t \theta_{N}(1)} \mathbf{1}_{\{\eta_{t}^{N} \in \Delta \}} \, ds \leq U_{1} + \sum_{k=1}^{N_{t \theta_{N}(1)}} U_{k+1} .$$

Let $\lambda_{N} = \max_{1 \leq j \leq \nu} \max_{y \in E_{j}} \sum_{z \not\in E_{j}} R_{N}(y, z) < 1$. We may estimate from below the random variables $\{V_{k} : k \geq 1 \}$ by independent exponential times of rate $\lambda_{N}$:

$$V_{k} \geq \hat{V}_{k} , \quad \text{where} \quad \{\hat{V}_{k} : k \geq 1 \} \text{is a sequence of i.i.d. mean } \lambda_{N}^{-1} \text{ exponential random variables, independent also from the sequence } \{U_{k} : k \geq 1 \} .$$

Let $\{\hat{N}_{t} : t \geq 0 \}$ be the Poisson process associated to the sequence $\{\hat{V}_{k} : k \geq 1 \}$.

Since the sequence $\{\hat{V}_{k} : k \geq 1 \}$ is independent of the sequence $\{U_{k} : k \geq 1 \}$, in view of the previous estimate,

$$E_{y}^{N} \left[ \int_{0}^{t \theta_{N}(1)} \mathbf{1}_{\{\eta_{t}^{N} \in \Delta \}} \, ds \right] \leq E_{y}^{N} \left[ U_{1} + \sum_{k=1}^{N_{t \theta_{N}(1)}} U_{k+1} \right] .$$

By Lemma 5.3 this expression is bounded by $C_{0} \{1 + t \theta_{N}(1) \lambda_{N} \}$, which proves condition (M3').

The proof of condition (M1') is similar to the one of Lemma 5.3. However, we may not estimate the expectation of $T_{\gamma}$, which might be very large if the process leaves the metastable set $\mathcal{E}_{i}$ before reaching the state $x_{i}$. We may of course assume that $\mathcal{E}_{i}$ is not a singleton so that $\sum_{y \in \mathcal{E}_{i}} R_{N}(y, z)$ is of magnitude one for all $y \in \mathcal{E}_{i}$. Recall that we denote by $\{\tau_{k} : k \geq 0 \}$ the successive jump times of $\eta_{t}^{N}$ and by $\{Y_{k}^{N} : k \geq 0 \}$ the jump chain. Fix $1 \leq i \leq \nu$, $x_{i} \in \mathcal{E}_{i}$ and let now $\lambda_{N} = \max_{y \in \mathcal{E}_{i}, \not\in \mathcal{E}_{i}} R_{N}(y, z) < 1$. For each $y \in \mathcal{E}_{i}$, there exists an open path $\gamma = (y_{0} = y, \ldots, y_{n(y)} = x)$ from $y$ to $x$ contained in $\mathcal{E}_{i}$. Let $n = \max \{n(y) : y \in \mathcal{E}_{i}, y \not\in x \}$.

There exists a constant $a$, independent of $N$, such that

$$\max_{y \in \mathcal{E}_{i}} P_{y}^{N} \left[ Y_{k}^{N} \neq x_{i}, 0 \leq k \leq n \right] \leq a < 1 .$$

On the one hand, for every $\ell \geq 1$, $y \in \mathcal{E}_{i}$,

$$P_{y}^{N} \left[ t_{\ell n} \leq \min \{T_{x_{i}}, T_{\mathcal{E}_{i}} \} \right] \leq P_{y}^{N} \left[ Y_{k}^{N} \neq x_{i}, Y_{k}^{N} \in \mathcal{E}_{i}, 0 \leq k \leq \ell n \right] .$$
By the Markov property and by the previous estimate, this expression is bounded by $a^\ell$. On the other hand, since the process jumps from $\mathcal{E}_i$ to $\mathcal{E}_i^c$ at rate $\lambda_N < 1$,

$$P_y^N[\tau_{n\ell} \geq T_{\mathcal{E}_i^c}] \leq P_y^N \left[ \bigcup_{k=1}^{n\ell} Y^N_k \not\in \mathcal{E}_i \right] \leq C_0 \ell n \lambda_N$$

for some finite constant $C_0$ independent of $N$.

In view of the previous bounds, to estimate $P_y^N[T_{x_i} > \delta \theta_N]$ it remains to consider the term

$$P_y^N[T_{x_i} > \delta \theta_N, T_{x_i} < \tau_{n\ell} < T_{\mathcal{E}_i^c}] \leq P_y^N[\delta \theta_N < \tau_{n\ell} < T_{\mathcal{E}_i^c}].$$

Since $\sum_{y \in E} R_N(y, z)$ is of magnitude one for all $y \in \mathcal{E}_i$, before leaving the set $\mathcal{E}_i$, we may estimate the times between jumps by i.i.d. exponential random times with finite mean independent of $N$. By Tchebycheff inequality, the previous expression is thus bounded by $C_0 n \ell / \delta \theta_N$ for some finite constant $C_0$ independent of $N$.

We have thus proved that for every $\delta > 0$, $y \in \mathcal{E}_i$, $\eta_N = 0$,

$$P_y^N[T_{x_i} > \delta \theta_N] \leq a^\ell + C_0 \ell n \lambda_N + \frac{C_0 n \ell}{\delta \theta_N}.$$  

The second assertion of the lemma follows by taking $N \uparrow \infty$ and then $\ell \uparrow \infty$. \hfill $\Box$

We conclude this section with two remarks. Denote by $P_N(x, i, j), 1 \leq i \neq j \leq \nu,$ $x \in \mathcal{E}_i$, the hitting probabilities

$$P_N(x, i, j) := P_x^N[T_{\mathcal{E}_j} = \mathcal{E}_i].$$

By Lemma 4.3, $P_N(x, i, j)$ converges to some $P(x, i, j) \in [0, 1]$. Since, by Proposition 5.7, $(\mathcal{E}_i, \mathcal{E}_i \cup \Delta, y), y \in \mathcal{E}_i$, is a valley, it is not difficult to show that the limit $P(x, i, j)$ does not depend on the starting point $x$. Therefore, by Lemma 10.2 for any $1 \leq i \neq j \leq \nu$,

$$r(i, j) = \lambda(i) p(i, j), \quad \text{where} \quad p(i, j) := \lim_{N \to \infty} P_x^N[T_{\mathcal{E}_j} = \mathcal{E}_i]$$

and where $\lambda(i)$ is defined in (6.1).

Consider a leave $\mathcal{E}_i, i \in S_1$, and a leave $\mathcal{E}_j$ such that $\mu_N(\mathcal{E}_j) < \mu_N(\mathcal{E}_i)$. By reversibility,

$$\mu_N(\mathcal{E}_i) r_N^\mathcal{E}_i(\mathcal{E}_j, \mathcal{E}_i) = \mu_N(\mathcal{E}_j) r_N^\mathcal{E}_j(\mathcal{E}_i, \mathcal{E}_j).$$

By (1) and Lemma 6.7, $r_N^\mathcal{E}_j(\mathcal{E}_i, \mathcal{E}_i) \leq r_N^\mathcal{E}_i(\mathcal{E}_j, \mathcal{E}_i) = \text{cap}_N(\mathcal{E}_j, \mathcal{E}_i)/\mu_N(\mathcal{E}_j) = 1/\theta_N(1)$, so that $\theta_N(1) r_N^\mathcal{E}_i(\mathcal{E}_j, \mathcal{E}_i)$ is bounded. Therefore, $\theta_N(1) r_N^\mathcal{E}_i(\mathcal{E}_j, \mathcal{E}_i)$ vanishes as $N \uparrow \infty$. We have just proved that

$$r(i, j) = \lim_{N \to \infty} \theta_N(1) r_N^\mathcal{E}_i(\mathcal{E}_j, \mathcal{E}_i) = 0 \quad \text{for all } j; \mu_N(\mathcal{E}_j) < \mu_N(\mathcal{E}_i).$$

Hence, in the asymptotic dynamics, the process may only jump from a leave $\mathcal{E}_i$ to a leave $\mathcal{E}_j$ if the measure of $\mathcal{E}_j$ is of the same or of a larger magnitude than the one of $\mathcal{E}_i$.

7. Multiscale analysis.

In the previous section, we proved that the Markov process $\{\eta^N_t : t \geq 0\}$ exhibits a metastable behaviour on the time scale $\theta_N(1)$ with metastates $\{\mathcal{E}_i : 1 \leq i \leq \nu\}$, metapoints $\{x_i : 1 \leq i \leq \nu\}$ and asymptotic Markov dynamics $\{P_x : 1 \leq i \leq \nu\}$.

We describe in this section, by a recursive argument, the metastable behaviour of the Markov process $\{\eta^N_t : t \geq 0\}$ on longer time scales. In the statement
of the hypothesis $T$ below, by convention, $\theta_N(0) \equiv 1$, $\nu(0) = |E|$ and the sets $\mathcal{E}_1^{(0)}, \ldots, \mathcal{E}_{\nu(0)}^{(0)}$ are all singletons of $E$.

**Assumption $T$ at level $p$:** For each $1 \leq k \leq p$ there exists a sequence $(\theta_N(k) : N \geq 1)$, $1 < \theta_N(k) < \theta_N(k + 1)$, $1 \leq k < p$, and a partition $\{\mathcal{E}_1^{(k)}, \ldots, \mathcal{E}_{\nu(k)}^{(k)}\}$ of the state space $E$, such that

- $(T1)$ $1 \leq \nu(k) < \nu(k - 1)$.
- $(T2)$ For $1 \leq i \leq \nu(k)$, $\mathcal{E}_i^{(k)} = \cup_{j \in I_k} \mathcal{E}_j^{(k-1)}$, where $I_{k,1}, \ldots, I_{k,\nu(k)}$ are disjoint subsets of $\{1, \ldots, \nu(k - 1)\}$.
- $(T3)$ For all $1 \leq i \leq \nu(k)$, $\mu_N(x) \approx \mu_N(\mathcal{E}_i^{(k)})$ for all $x \in \mathcal{E}_i^{(k)}$.
- $(T4)$ There exists a positive constant $C_1$, independent of $N$, such that for all $1 \leq i \leq \nu(k)$ and all $x, y \in \mathcal{E}_i^{(k)}$, $x \neq y$, $\text{cap}_N(x, y) \geq C_1 \mu_N(\mathcal{E}_i^{(k)}) / \theta_N(k - 1)$.
- $(T5)$ For all $1 \leq i \leq \nu(k)$, $\mu_N(\mathcal{E}_i^{(k)}) / \text{cap}_N(\mathcal{E}_i^{(k)}, \mathcal{E}_i^{(k)}) \geq \theta_N(k)$, where $\mathcal{E}_i^{(k)} = \cup_{j \neq i} \mathcal{E}_j^{(k)}$.

Let

$$\mathcal{E}^{(k)} = \bigcup_{i=1}^{\nu(k)} \mathcal{E}_i^{(k)}, \quad S_k = \left\{ i : \frac{\mu_N(\mathcal{E}_i^{(k)})}{\text{cap}_N(\mathcal{E}_i^{(k)}, \mathcal{E}_i^{(k)})} \approx \theta_N(k) \right\}.$$ 

Then,

$$\lim_{N \to \infty} \theta_N(k) r_N^{(k)} (\mathcal{E}_i^{(k)}, \mathcal{E}_j^{(k)}) = r_k(i, j), \quad 1 \leq i \neq j \leq \nu(k),$$

$$\sum_{j \neq i} r_k(i, j) > 0 \text{ for each } i \in S_k \text{ and } \sum_{j \neq i} r_k(i, j) = 0 \text{ for each } i \notin S_k, \quad (7.1)$$

and $r_k(i, j) = 0$ if $\mu_N(\mathcal{E}_j^{(k)}) < \mu_N(\mathcal{E}_i^{(k)})$.

Moreover, recall the definition of the speeded up blind process $X_{\nu(k)} = \Psi_k(\eta_{\theta_N(k)})$ introduced in the statement of Theorem 2.1. For every $1 \leq i \leq \nu(k)$, and $x \in \mathcal{E}_i^{(k)}$, under the measure $P_x^N$,

the speeded up blind process $X_{\nu(k)}$ converges (7.2)

to a Markov process on $\{1, \ldots, \nu(k)\}$ characterized by rates $r_k(l, m)$, $1 \leq l \neq m \leq \nu(k)$, starting from $i$.

- $(T7)$ Property (M1') of metastability holds. For every $1 \leq i \leq \nu(k)$, every $x \in \mathcal{E}_i^{(k)}$ and $\delta > 0$,

$$\lim_{N \to \infty} \max_{y \in \mathcal{E}_i^{(k)}} P_y^N [T_x > \delta \theta_N(k)] = 0.$$ 

- $(T8)$ Property (M3') of metastability holds. For every $t > 0$,

$$\lim_{N \to \infty} \max_{x \in E} E_x^N \left[ \int_0^t 1 \{ \eta_{\theta_N(k)}^N \in \Delta_k \} \, ds \right] = 0.$$ 

Note that all these properties have been proved in the previous section for $p = 1$ with $\nu(1) = \nu$; $\mathcal{E}_1^{(1)}, \ldots, \mathcal{E}_{\nu(1)}^{(1)}$, $\Delta_1$ given by the sets $\mathcal{E}_1, \ldots, \mathcal{E}_\nu$, $\Delta$ defined just before (5.1); $\theta_N(1) = \theta_N = p_N(1)$ defined at the beginning of Section 6 and $r_1 = r$ defined at Lemma 6.1.

The main result of this section states that if Assumption $T$ holds at level $p$ and $\nu(p) \geq 2$, then it holds at level $p + 1$. 

To begin the recursive argument, suppose that \( \nu(p) > 1 \). We first describe the metastates at level \( p + 1 \). We say that there exists an open path from \( E_a^{(p)} \) to \( E_b^{(p)} \) if there exists a sequence \( a = a_0, a_1, \ldots, a_n = b \) such that \( \tau_p(a_k, a_{k+1}) > 0 \), where \( \tau_p \) is the asymptotic jump rate introduced in (7.2). We say that two sets \( E_a^{(p)}, E_b^{(p)} \) are equivalent, \( E_a^{(p)} \sim E_b^{(p)} \), if there exist an open path from \( E_a^{(p)} \) to \( E_b^{(p)} \) and an open path from \( E_b^{(p)} \) to \( E_a^{(p)} \).

Two equivalent sets \( E_a^{(p)}, E_b^{(p)} \) have measure of the same magnitude. Indeed, if \( E_a^{(p)}, E_b^{(p)} \) are equivalent, there exists an open path \( (a = a_0, \ldots, a_n = b, \ldots, a_{n+m} = a) \) from \( E_a^{(p)} \) to \( E_a^{(p)} \) passing by \( E_b^{(p)} \). By (7.1), \( \mu_N(E_a^{(p)}) \leq \mu_N(E_b^{(p)}) \), \( 0 \leq i < n + m \). Since \( E_a = E_{a_{n+m}} = E_a^{(p)} \), we obtain that

\[
\mu_N(E_a^{(p)}) \approx \mu_N(E_b^{(p)}),
\]

as claimed.

We call a metastate in the time scale \( \theta_N(k) \) a \( k \)-metastate. If we declare a \( p \)-metastate equivalent to itself, the relation \( \sim \) introduced in the penultimate paragraph becomes an equivalent relation among the \( p \)-metastates \( E_1^{(p)}, \ldots, E_{\nu(p)}^{(p)} \). Denote by \( C_1^{(p+1)}, C_2^{(p+1)}, \ldots, C_{\alpha(p+1)}^{(p+1)} \) the equivalent classes. Some equivalent classes are connected to other equivalent classes. By drawing an arrow from a set \( C_i^{(p+1)} \) to a set \( C_j^{(p+1)} \) if there exist \( E_a^{(p)} \subset C_i^{(p+1)}, E_b^{(p)} \subset C_j^{(p+1)} \) such that \( \tau_p(a, b) > 0 \), the set \( \{C_1^{(p+1)}, \ldots, C_{\alpha(p+1)}^{(p+1)}\} \) becomes an oriented graph with no directed loops. We denote by \( E_1^{(p+1)}, E_2^{(p+1)}, \ldots, E_{\nu(p+1)}^{(p+1)} \) the leaves of this graph, i.e., the set of equivalent classes with no successors in the terminology of graph theory, and by \( \Delta_{p+1} \) the union of the remaining sets so that \( \{E_1^{(p+1)}, \ldots, E_{\nu(p+1)}^{(p+1)}, \Delta_{p+1}, \Delta_{p+1} = \Delta_{p+1} \cup \Delta_p \} \), forms a partition of \( E \):

\[
E = E_1^{(p+1)} \cup \Delta_{p+1}, \quad E_i^{(p+1)} = E_i^{(p+1)} \cup \cdots \cup E_{\nu(p+1)}^{(p+1)}.
\]

For \( 1 \leq i \leq \nu(p+1) \), let \( \hat{E}_i^{(p+1)} \) be the union of all leaves except \( E_i^{(p+1)} \):

\[
\hat{E}_i^{(p+1)} = \bigcup_{j \neq i} E_j^{(p+1)}.
\]

We may now state the main result of this section.

**Theorem 7.1.** Let \( \{\eta^N_t : t \geq 0\} \) be a sequence of irreducible, reversible Markov processes on a finite state space \( E \) satisfying assumptions (2.1) and (2.2). Suppose that Assumption \( T \) at level \( p \) holds and that \( \nu(p) \geq 2 \). Define \( \nu(p+1), E_{i}^{(p+1)}, \hat{E}_{i}^{(p+1)}, 1 \leq i \leq \nu(p+1), \Delta_{p+1}, \Delta_{p+1}^{\circ} \) as above. Then,

1. For \( 1 \leq i \leq \nu(p+1) \) and \( x \) in \( E_{i}^{(p+1)} \), the triple \( (E_{i}^{(p+1)}, E_{i}^{(p+1)} \cup \Delta_{p+1}^{\circ}, x) \)

   is a valley for the trace process \( \{\eta^N_t : t \geq 0\} \) of depth \( \theta_N,i \) \( = \mu_N(E_{i}^{(p+1)})/\cap N(E_{i}^{(p+1)}, E_{i}^{(p+1)}). \)

2. The sequences \( \{\theta_N,i : N \geq 1\} \), \( 1 \leq i \leq \nu(p+1) \) are comparable.

3. Let \( \theta_{N,p} + 1 \) = \( \min\{\theta_N,i : 1 \leq i \leq \nu(p+1)\} \). Then, \( \theta_{N,p} + 1 \) \( > \theta_{N,p} \).

4. Assumption \( T \) at level \( p+1 \) holds.

In the next remark, we summarize what informations are needed in each model to prove all its metastable behavior. It says, in essence, that to prove the metastable
behavior of a particular dynamics, we need only to obtain informations on the measure, on the capacity and on the hitting times of subsets of the process.

**Remark 7.2.** In the applications, once the metastable behavior in the time scale $\theta_N(1)$ among the shallowest valleys has been determined, we shall use Theorem 7.1 to describe the metastable behavior of the process in the longer time scales. We first characterize the $k$-metastates following the recipe presented above the statement of Theorem 7.1. According to this theorem, the $k$-metastates form valleys of different depths. To determine the time scale at which metastability at level $k$ can be observed we need to compute the depth of each valley. This computation requires estimates on the capacities among metastates and estimates on the measure of each metastate. Once this has been done, we may define the time scale $\theta_N(k)$. At this point, to complete the description of the metastable behavior of the process at level $k$, it remains to obtain the rates $r_k(i,j)$. Theorem 7.1 asserts that the asymptotic rates $r_k(i,j)$ exist. By the rates may be expressed in terms of the asymptotic depths of the valleys and the hitting probabilities of the metastates. Hence, to conclude we need to compute in each model, the limit of the hitting probabilities defined in 7.5, which exist in virtue of Lemma 7.2.

For some evolutions, as the Kawasaki dynamics, it may be difficult to obtain an exact expression for the limit of the hitting probabilities. Nevertheless, if we may at least determine if the rates $r_k(i,j)$ are positive or equal to 0, we may apply Theorem 7.1 and determine the time scales at which a metastable behavior is observed and the metastates at each time scale, without an exact knowledge of the asymptotic dynamics among the metastates.

The proof of Theorem 7.1 is divided in several lemmas. We first show that conditions (T1) and (T2) are satisfied for $k = p + 1$.

**Lemma 7.3.** We have that $\nu(p + 1) < \nu(p)$ and that $E_i^{(p + 1)} = \cup_{a \in I_p+1,i} E_a^{(p)}$, $1 \leq i \leq \nu(p + 1)$, where $I_{p+1}, \ldots, I_{p+1,\nu(p+1)}$ are disjoint subsets of $\{1, \ldots, \nu(p)\}$.

**Proof.** A $p$-metastate $E_a^{(p)}$, $a \in S_p$, is either contained in $\Delta_{p+1}^a$ or part of a larger valley $E_i^{(p+1)}$, in the sense that $E_a^{(p)} \subseteq E_i^{(p+1)}$, because by (7.3) each p-metastate whose index belongs to $S_p$ has at least one successor. In particular, the number of leaves at level $p + 1$ is strictly smaller than the number of $p$-metastates so that $\nu(p + 1) < \nu(p)$, proving condition (T1). Condition (T2) follows from the construction.

Next lemma shows that conditions (T3), (T4) are in force for $k = p + 1$.

**Lemma 7.4.** For all $1 \leq i \leq \nu(p + 1)$, $x \in E_i^{(p+1)}$, $\mu_N(x) \approx \mu_N(E_i^{(p+1)})$. Moreover, there exists a positive constant $C_1$ such that for all $1 \leq i \leq \nu(p + 1)$ and all $x$, $y \in E_i^{(p+1)}$, $x \neq y$, $\text{cap}_N(x,y) \geq C_1 \mu_N(E_i^{(p+1)})/\theta_N(p)$.

**Proof.** Fix $1 \leq i \leq \nu(p + 1)$, $x \in E_i^{(p+1)}$. By definition, the leave $E_i^{(p+1)}$ is the union of $p$-metastates: $E_i^{(p+1)} = \cup_{a \in I} E_a^{(p)}$, where $I$ is a subset of $\{1, \ldots, \nu(p)\}$.

By (7.3), all $p$-metastates $E_a^{(p)}$, $a \in I$, have measures of the same magnitude so that $\mu_N(E_i^{(p+1)}) \approx \mu_N(E_a^{(p)})$ for all $a \in I$. By assumption (T3) for $k = p$, $\mu_N(y) \approx \mu_N(E_a^{(p)})$ for all $y \in E_a^{(p)}$, which proves the first claim of the lemma.
To prove the second claim, fix $x, y$ in $E_i^{(p+1)}$. If $x, y$ belong to the same set $E_i^{(p)}$, the lemma follows from assumption (T4) for $k = p$, the first part of the lemma and the fact that $\theta_N(p - 1) < \theta_N(p)$.

Assume that $x, y$ belongs to different $p$-metastates, say $x \in E_i^{(p)}$, $y \in E_b^{(p)}$, $a \neq b$. Since $E_a^{(p)} \sim E_b^{(p)}$, there exists an open path, $a = a_0, \ldots, a_m = b$, from $E_a^{(p)}$ to $E_b^{(p)}$. This means that $\theta_N(p) r_N^{(p)}(E_{a_0}, E_{a_{m+1}})$ converges to a positive number for $0 \leq m < n$. Therefore, by (10.3), there exists a positive number $C_0 > 0$, independent of $N$ and which may change from line to line, such that

$$\frac{\theta_N(p) \text{cap}_N(E_{a_0}^{(p)}, E_{a_{m+1}}^{(p)})}{\mu_N(E_{a_0}^{(p)})} \geq C_0$$

for all $N$ large enough and $0 \leq m < n$. Since by Lemma 7.4 cap$_N(A, B) \approx G_N(A, B)$, $G_N(E_{a_0}^{(p)}, E_{a_{m+1}}^{(p)}) \geq C_0 \mu_N(E_{a_0}^{(p)}) / \theta_N(p)$. There exists, in particular, a path $\gamma_m$ from $x_m \in E_{a_0}^{(p)}$ to $y_{m+1} \in E_{a_{m+1}}^{(p)}$, $0 \leq m < n$, with $G_N(\gamma_m) \geq C_0 \mu_N(E_{a_0}^{(p)}) / \theta_N(p)$.

By assumption (T4) for $k = p$ and similar arguments to the ones used above, there exist a path $\gamma_{0}$ from $x \in E_i^{(p)}$ to $x_0 \in E_i^{(p)}$ such that $G_N(\gamma_0) \geq C_0 \mu_N(E_i^{(p)}) / \theta_N(p - 1)$; paths $\gamma_m$ from $y_m \in E_i^{(p)}$ to $x_{m+1} \in E_i^{(p)}$, $1 \leq m < n$, such that $G_N(\gamma_m) \geq C_0 \mu_N(E_i^{(p)}) / \theta_N(p - 1)$; and path $\gamma_n$ from $y_n \in E_i^{(p)}$ to $y \in E_i^{(p)}$ such that $G_N(\gamma_n) \geq C_0 \mu_N(E_i^{(p)}) / \theta_N(p - 1)$.

Since, by the first part of the lemma, $\mu_N(E_i^{(p+1)}) \approx \mu_N(E_c^{(p)})$ for all $c \in I$, juxtaposing all these paths, we obtain a path $\gamma$ from $x$ to $y$ such that $G_N(\gamma) \geq C_0 \mu_N(E_i^{(p+1)}) / \theta_N(p)$. This shows that

$$\text{cap}_N(x, y) \approx G_N(\{x\}, \{y\}) \geq G_N(\gamma) \geq \frac{C_0 \mu_N(E_i^{(p+1)})}{\theta_N(p)},$$

which proves the lemma.

We next show that condition (T7) is in force on any time scale longer than $\theta_N(p)$.

**Lemma 7.5.** Let $\{\theta_N : N \geq 1\}$ be a sequence such that $\theta_N > \theta_N(p)$. Then for every $1 \leq i \leq \nu(p + 1)$, $x \in E_i^{(p+1)}$ and $\delta > 0$,

$$\lim_{N \to \infty} \max_{y \in E_i^{(p+1)}} P_N^y [T_x > \delta \theta_N] = 0.$$

**Proof.** Fix $1 \leq i \leq \nu(p + 1)$, $x, y \in E_i^{(p+1)}$ and $\delta > 0$. Denote by $E_i^{(p)} \subset E_i^{(p+1)}$ the $p$-metastates which contain $x, y$, respectively. Since $\theta_N > \theta_N(p)$, by the strong Markov property, for every $t > 0$ and for every $N$ large enough,

$$P_N^y [T_x > \delta \theta_N] \leq P_N^y [T_{E_i} > t \theta_N(p)] + \max_{z \in E_i^{(p)}} P_N^z [T_z > \delta \theta_N / 2]. \quad (7.4)$$

We claim that both expression vanishes as $N \uparrow \infty$ and then $t \uparrow \infty$. Denote by $T_{E_i}^{(p)}$ the hitting time of $E_i^{(p)}$ by the trace process $\eta_i^{N,p}$ defined just before (12.2).

The first term on the right hand side of the previous formula is bounded above by

$$P_N^y \left[ \int_0^t 1 \{\eta_i^{N,p} \in \Delta_p\} ds > \epsilon \right] + P_N^y \left[ T_{E_i}^{(p)} > (t - \epsilon) \theta_N(p) \right]$$
for every $0 < \epsilon < t$. By property (T8) for $k = p$, the first term vanishes as $N \uparrow \infty$ for every $\epsilon > 0$. By the convergence of the process $\Psi_p(\eta^{N,p}_{\theta N}(p))$ to the Markov process with rates $r_p(i,j)$, assumed in (T6), the second term converges as $N \uparrow \infty$ to $\mathbb{P}_b[T_a > (t - \epsilon)]$, where $T_a$ stands for the hitting time of $a$. Since $\mathcal{E}^{(p+1)}_i$ is a leave, the asymptotic dynamics is an irreducible Markov process on the set of indices $c \in \{1, \ldots, \nu(p)\}$ such that $\mathcal{E}^{(p)}_i \subseteq \mathcal{E}^{(p+1)}_i$. In particular, $\mathbb{P}_b[T_a > (t - \epsilon)]$ vanishes as $t \uparrow \infty$. This proves that the first term in (7.3) vanishes as $N \uparrow \infty$ and then $t \uparrow \infty$.

The second term in (7.3) vanishes as $N \uparrow \infty$ by property (T7) for $k = p$. This proves the lemma.

Next lemma shows that we may from now on restrict our attention to the trace process $\{\eta^N_t : t \geq 0\}$ in our investigation of the metastability of $\{\eta^N_t : t \geq 0\}$ on a time scale longer than $\theta_N(p)$.

Lemma 7.6. Assume that the trace process $\{\eta^N_t : t \geq 0\}$ satisfy condition (T8) on some time scale $\theta_N \geq \theta_N(p)$ and for some subset $\Delta^*_{p+1}$ of $\mathcal{E}^{(p)}$:

$$\lim_{N \to \infty} \max_{N \in \mathcal{E}^{(p)}} E^N_{x} \left[ \int_0^t \mathbb{1}_{\eta^N_{\theta N} \in \Delta^*_{p+1}} ds \right] = 0 .$$

Then, the same property holds for the Markov process $\{\eta^N_t : t \geq 0\}$ with $\Delta_p \cup \Delta^*_{p+1}$ in place of $\Delta^*_{p+1}$:

$$\lim_{N \to \infty} \max_{N \in \mathcal{E}^{(p)}} E^N_{x} \left[ \int_0^t \mathbb{1}_{\eta^N_{\theta N} \in \Delta_p \cup \Delta^*_{p+1}} ds \right] = 0 .$$

Proof. Fix $x \in E$ and observe that

$$E^N_{x} \left[ \int_0^t \mathbb{1}_{\eta^N_{\theta N} \in \Delta_p \cup \Delta^*_{p+1}} ds \right] \leq E^N_{x} \left[ \int_0^t \mathbb{1}_{\eta^N_{\theta N} \in \Delta_p} ds \right] + \max_{y \in \mathcal{E}^{(p)}} E^N_{y} \left[ \int_0^t \mathbb{1}_{\eta^N_{\theta N} \in \Delta^*_{p+1}} ds \right].$$

The second term vanishes as $N \uparrow \infty$ by assumption. The first one is bounded by

$$\frac{\theta_N(p)}{\theta_N} \sum_{n=0}^{[\log(\theta_N(p))] - 1} E^N_{x} \left[ \int_{nt}^{(n+1)t} \mathbb{1}_{\eta^N_{\theta_N(x)}(p) \in \Delta_p} ds \right],$$

where $[r]$ stands for the integer part of $r$. By the Markov property, this expression is bounded above by

$$2 \max_{y \in E} E^N_{y} \left[ \int_0^t \mathbb{1}_{\eta^N_{\theta_N(y)}(p) \in \Delta_p} ds \right],$$

which vanishes as $N \uparrow \infty$ in virtue of (T8) for $k = p$. □

Consider the trace process $\{\eta^N_t : t \geq 0\}$. By formula (6.12) in [1], its invariant probability measure is the measure $\mu_N$ conditioned to $\mathcal{E}^{(p)}$, and by [1] Lemma 6.9 the capacity between two disjoint subsets of $\mathcal{E}^{(p)}$ for the trace process $\{\eta^N_t : t \geq 0\}$ is equal to the capacity for the original process divided by $\mu_N(\mathcal{E}^{(p)})$.

The evolution the trace process $\{\eta^N_t : t \geq 0\}$ on $\mathcal{E}^{(p)}$ is similar to the one of $\{\eta^N_t : t \geq 0\}$ among the shallowest valleys. We claim, for instance, that $(\mathcal{E}^{(p+1)}_i, \mathcal{E}^{(p+1)}_i)$,
x), x ∈ E_i^{(p+1)}, 1 ≤ i ≤ ν(p, +1), are valleys for the trace process \{η_i^{N,p} : t ≥ 0\}. The proof of this assertion is divided in several steps. We first show that

\[
G_N(E_i^{(p+1)}, E_i^{(p+1)}) = \frac{\mu_N(E_i^{(p+1)})}{\theta_N(p)}, \quad 1 ≤ i ≤ ν(p+1).
\] (7.5)

Indeed, since E_i^{(p+1)} is a leave, there is no open path from some E_a^{(p)} ⊂ E_i^{(p+1)} to some E_b^{(p)} \not\subset E_i^{(p+1)}. Therefore, since by Lemma 7.4, \mu_N(x) ≈ \mu_N(E_i^{(p+1)}), x ∈ E_i^{(p+1)}, by the definition of the average rate,

\[
\lim_{N \to \infty} \theta_N(p) r_N^{(p)}(E_i^{(p+1)}, \bigcup_b E_b^{(p)}) = \lim_{N \to \infty} \theta_N(p) \sum_a r_N^{(p)}(E_a^{(p)}, \bigcup_b E_b^{(p)}) = 0,
\]

where the sum is performed over all p-metastates E_a^{(p)} ⊂ E_i^{(p+1)} and the union over all p-metastates E_b^{(p)} \not\subset E_i^{(p+1)}. Hence, by Lemma 6.7 and Lemma 6.9 in [1], we only need to check that \[ \lim_{N \to \infty} \theta_N(p) R_N^{(p)}(E_i^{(p+1)}, \bigcup_b E_b^{(p)}) = 0. \] (7.6)

This proves (7.5) in view of (4.2) and because E_i^{(p+1)} ⊂ \cup_b E_b^{(p)}.

Recall the definition of the set \[ Δ_a^{p+1} \] introduced just before Lemma 7.4. Denote by B_i^{(p+1)}, 1 ≤ i ≤ ν(p+1), the union of all p-metastates E_b^{(p)} which have measure of lower magnitude than E_i^{(p+1)} and which are contained in \[ Δ_a^{p+1}. \] Let also \[ \mathcal{F}_i^{(p+1)} = E_i^{(p)} \setminus [E_i^{(p+1)} \cup B_i^{(p+1)}], \quad 1 ≤ i ≤ ν(p+1). \]

**Lemma 7.7.** Fix 1 ≤ i ≤ ν(p+1) and x ∈ E_i^{(p+1)}. The triple \( (E_i^{(p+1)}, E_i^{(p+1)} \cup E_i^{(p+1)}, x) \) is a valley for the trace process \{η_i^{N,p} : t ≥ 0\} of depth \( θ_{N,i} = μ_N(E_i^{(p+1)})/\text{cap}_N(E_i^{(p+1)}, E_i^{(p+1)}) \). Moreover, \( θ_{N,i} ≥ θ_N(p) \).

**Proof.** Fix 1 ≤ i ≤ ν(p+1) and x ∈ E_i^{(p+1)}. In view of Theorem 2.6, formula (6.12) and Lemma 6.9 in [1], we only need to check that

\[
\lim_{N \to \infty} \max_{y \in E_i^{(p+1)}} \frac{\text{cap}_N(E_i^{(p+1)}, \mathcal{F}_i^{(p+1)})}{\text{cap}_N(x, y)} = 0.
\]

This follows from Lemma 7.4, Lemma 4.1 (4.2) and (7.6).

It remains to show that \( θ_{N,i} ≥ θ_N(p) \). Since \( \mathcal{F}_i^{(p+1)} \) is contained in \( \cup_b E_b^{(p)} \), where the union is performed over all p-metastates which are not contained in \( E_i^{(p+1)} \), and since \( \text{cap}_N(A, B) ≤ \text{cap}_N(A, C) \) if \( B \subset C \), by Lemma 4.1, \( θ_N(p)/θ_{N,i} \) is bounded above by

\[
C_1 θ_N(p) \frac{G_N(E_i^{(p+1)}, \bigcup_b E_b^{(p)})}{\mu_N(E_i^{(p+1)})}
\]

for some finite constant \( C_1 \) independent of \( N \). By (7.6) this expression vanishes as \( N \to \infty \).

Denote by \( P_{x}^{N,p}, x ∈ E_i^{(p)} \), the probability on the path space \( D(\mathbb{R}_+, E^{(p)}) \) induced by the trace process \{η_i^{N,p} : t ≥ 0\} starting from \( x \).
Lemma 7.8. Fix $1 \leq i \leq \nu(p + 1)$ and $x \in \mathcal{E}_i^{(p+1)}$. The triple $(\mathcal{E}_i^{(p+1)}, \mathcal{E}_i^{(p+1)} \cup \Delta_{p+1}^0, x)$ is a valley for the trace process $\{N_i^p : t \geq 0\}$ of depth $\theta_{N,i} = \mu_N(\mathcal{E}_i^{(p+1)})/\cap_N(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)})$. Moreover, $\cap_N(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)}) \approx \cap_N(\mathcal{E}_i^{(p+1)}, \bar{\mathcal{E}}_i^{(p+1)})$.

Proof. Fix $1 \leq i \leq \nu(p + 1)$ and recall the definition of $\theta_{N,i}$ introduced in Lemma 7.4. By this lemma and by Lemma 10.1, to prove the first assertion we need to show that for every $\delta > 7.7$.

$$\lim_{N \to \infty} \max_{y \in \Delta_{p+1}^0 \setminus \mathcal{B}_i^{(p+1)}} P^N_{y}[T_{\mathcal{E}_i^{(p+1)}} > \delta \theta_{N,i}] = 0.$$ 

Since, by Lemma 7.1, $\theta_{N,i} > \theta_N(p)$, it is enough to show that

$$\lim_{t \to \infty} \lim_{N \to \infty} \max_{y \in \Delta_{p+1}^0 \setminus \mathcal{B}_i^{(p+1)}} P^N_{y}[T_{\mathcal{E}_i^{(p+1)}} > t \theta_N(p)] = 0.$$

Fix $y \in \Delta_{p+1}^0 \setminus \mathcal{B}_i^{(p+1)}$. By definition, $y$ belongs to some $p$-metastate $\mathcal{E}_b^{(p)} \not\subseteq \mathcal{E}_i^{(p+1)}$ and $\mu_N(\mathcal{E}_b^{(p)}) \geq \mu_N(\mathcal{E}_i^{(p+1)})$. We claim that there is no open path from $\mathcal{E}_b^{(p)}$ to $\mathcal{E}_i^{(p+1)}$.

Indeed, suppose that there is an open path. In this case, since $\mu_N(\mathcal{E}_b^{(p)}) \geq \mu_N(\mathcal{E}_i^{(p+1)})$, by (7.4), we necessarily have $\mu_N(\mathcal{E}_b^{(p)}) \approx \mu_N(\mathcal{E}_i^{(p+1)})$. Considering the last two $p$-metastates of the open path from $\mathcal{E}_b^{(p)}$ to $\mathcal{E}_i^{(p+1)}$, we find a $p$-metastate $\mathcal{E}_c^{(p)} \not\subseteq \mathcal{E}_i^{(p+1)}$, $\mu_N(\mathcal{E}_c^{(p)}) \approx \mu_N(\mathcal{E}_i^{(p+1)})$, and a $p$-metastate $\mathcal{E}_a^{(p)} \subseteq \mathcal{E}_i^{(p+1)}$ such that $r_p(c, a) > 0$. Therefore, by (7.4) and by reversibility,

$$r_p(a, c) = \lim_{N \to \infty} \theta_N(p) \frac{r_p(c, \mathcal{E}_a^{(p)} \mathcal{E}_c^{(p)})}{\mu_N(\mathcal{E}_c^{(p)})} = \lim_{N \to \infty} \frac{\mu_N(\mathcal{E}_c^{(p)})}{\mu_N(\mathcal{E}_a^{(p)})} \theta_N(p) r_p(c, \mathcal{E}_a^{(p)} \mathcal{E}_c^{(p)}) = r_p(a, c) \lim_{N \to \infty} \frac{\mu_N(\mathcal{E}_c^{(p)})}{\mu_N(\mathcal{E}_a^{(p)})} > 0,$$

which contradicts the fact that $\mathcal{E}_i^{(p+1)}$ is a leave.

By (7.2) with $k = p$, starting from $y$ the process $X_{\theta_N(p)}^{N,i}$ converges to the Markov process on $\{1, \ldots, \nu(p)\}$ with rates $r_p$ starting from $b$. Therefore,

$$\lim_{N \to \infty} P^N_{y}[T_{\mathcal{E}_i^{(p+1)}} > t \theta_N(p)] \leq P_b[T_A > t ] ,$$

where $A = \{c : \mathcal{E}_c^{(p)} \subset \mathcal{E}_i^{(p+1)}\}$. Since there is no open path from $\mathcal{E}_b^{(p)}$ to $\mathcal{E}_i^{(p+1)}$ and since $\mathcal{E}_b^{(p)} \subset \Delta_{p+1}^0$, the state $b$ is transient for the Markov process on $\{1, \ldots, \nu(p)\}$ with rates $r_p$ and all its limit points are contained in $A$. Hence, $P_b[T_A > t ]$ vanishes as $t \to \infty$. This proves the first assertion of the lemma.

To prove the second statement, note that $\cap_N(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)}) \geq \cap_N(\mathcal{E}_i^{(p+1)}, \bar{\mathcal{E}}_i^{(p+1)})$ because $\bar{\mathcal{E}}_i^{(p+1)} \subseteq \mathcal{F}_i^{(p+1)}$.

By Lemma 3.1, to prove the reverse inequality we may replace the capacities by the function $G_N$. There exists a path $\gamma = (x_0, \ldots, x_n)$ from $\mathcal{E}_i^{(p+1)}$ to $\mathcal{F}_i^{(p+1)}$ such that $G_N(\gamma) = G_N(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)})$. If $x_n$ belongs to $\mathcal{E}_i^{(p+1)}$, we have that $G_N(\gamma) \leq G_N(\mathcal{E}_i^{(p+1)}, \bar{\mathcal{E}}_i^{(p+1)})$ and the statement is proved.

If, on the other hand, $x_n$ belongs to some metastate $\mathcal{E}_b^{(p)} \subset \Delta_{p+1}^0 \setminus \mathcal{B}_i^{(p+1)}$, we proceed as follows. We have already showed in the first part of the proof that there exists an open path from $\mathcal{E}_b^{(p)}$ to $\mathcal{E}_i^{(p+1)}$. Repeating the arguments presented in the proof of Lemma 7.1 and keeping in mind the second assertion of
In particular, by Lemma 4.2, we show that there exists a path $\hat{\gamma}$ from $x_n$ to $\hat{\mathcal{E}}(p+1)$ such that $G_N(\hat{\gamma}) \geq C_0 \mu_N(x_n)/\theta_N(p)$ for some finite constant $C_0$ independent of $N$. By definition of $\mathcal{B}_i^{(p+1)}$, this latter expression is bounded below $C_0 \mu_N(\mathcal{E}_i^{(p+1)})/\theta_N(p)$. By (7.6), $G_N(\gamma) = G_N(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)}) < \mu_N(\mathcal{E}_i^{(p+1)})/\theta_N(p)$. Hence, if we denote by $\gamma \oplus \hat{\gamma}$ the juxtaposition of $\gamma$ and $\hat{\gamma}$, we have a path $\gamma \oplus \hat{\gamma}$ from $\mathcal{E}_i^{(p+1)}$ to $\mathcal{E}_i^{(p+1)}$ such that $G_N(\gamma \oplus \hat{\gamma}) = G_N(\gamma) = G_N(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)})$. This proves the second assertion of the lemma.

It follows from the two previous lemmas that the depth $\theta_N, i$ of the valley $(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)}) \cup \Delta_i^{p+1}, x, 1 \leq i \leq \nu(p + 1)$, is of the same magnitude as $\mu_N(\mathcal{E}_i^{(p+1)})/\text{cap}_N(\mathcal{E}_i^{(p+1)})$ and much larger than $\theta_N(p)$. Fix a subset $I$ of $\{1, \ldots, \nu(p + 1)\}$ and let $J = \{1, \ldots, \nu(p + 1)\} \setminus I$. $\mathcal{E}_{K, p+1} = \bigcup_{i \in K} \mathcal{E}_i^{(p+1)}, K \subset \{1, \ldots, \nu(p + 1)\}$. By Lemma 4.3, the following limit exists

$$f_{I, J}(p+1)(x) := \lim_{N \to \infty} \mathbb{P}_x \left[ T_{\mathcal{E}_{I, p+1}} < T_{\mathcal{E}_{J, p+1}} \right].$$

In particular, by Lemma 4.2,

$$\lim_{N \to \infty} \frac{\text{cap}_N(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)})}{\mathbb{G}(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)})} = 1 \sum g(x, y) \left[f_i^{(p+1)}(y) - f_i^{(p+1)}(x)\right]^2 \in (0, \infty),$$

where the sum on the right hand side is performed over all pairs $(x, y) \in \mathcal{B}(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)})$. By the same reasons, the limit

$$f_i^{(p+1)}(x) := \lim_{N \to \infty} \mathbb{P}_x \left[ T_{\mathcal{E}_i^{(p+1)}} < T_{\mathcal{E}_i^{(p+1)}} \right]$$

exists and

$$\lim_{N \to \infty} \frac{\text{cap}_N(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)})}{\mathbb{G}(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)})} = 1 \sum g(x, y) \left[f_i^{(p+1)}(y) - f_i^{(p+1)}(x)\right]^2 \in (0, \infty),$$

where the sum on the right hand side is performed over all pairs $(x, y) \in \mathcal{B}(\mathcal{E}_i^{(p+1)}, \mathcal{F}_i^{(p+1)})$. Let $g_i^{(p+1)} = f_i^{(p+1)}$ for $I = \{i\}$. We claim that $g_i^{(p+1)} = f_i^{(p+1)}$, in other words, that for all $x \in E$,

$$\lim_{N \to \infty} \mathbb{P}_x \left[ T_{\mathcal{E}_i^{(p+1)}} < T_{\mathcal{E}_i^{(p+1)}} \right] = \lim_{N \to \infty} \mathbb{P}_x \left[ T_{\mathcal{E}_i^{(p+1)}} < T_{\mathcal{E}_i^{(p+1)}} \right]. \quad (7.7)$$

Indeed, fix $x \in E$. Since $\lim_{N \to \infty} \mathbb{P}_x \left[ T_{\mathcal{E}^{(p)}} = T_{y} \right], y \in \mathcal{E}^{(p)}$, exists by Lemma 4.3 and since all sets involved are contained in $\mathcal{E}^{(p)}$, taking conditional expectation with respect to $T_{\mathcal{E}^{(p)}}$ and applying the strong Markov property, to prove (7.7) it is enough to show that for all $y \in \mathcal{E}^{(p)}$

$$\lim_{N \to \infty} \mathbb{P}_y \left[ T_{\mathcal{E}_i^{(p+1)}} < T_{\mathcal{E}_i^{(p+1)}} \right] = \lim_{N \to \infty} \mathbb{P}_y \left[ T_{\mathcal{E}_i^{(p+1)}} < T_{\mathcal{E}_i^{(p+1)}} \right].$$

At this point we may replace the process $\eta_i^N$ by the trace process $\eta_i^{N, p}$. Since $\mathcal{E}_i^{(p+1)}$ is contained in $\mathcal{F}_i^{(p+1)}$, by the strong Markov property, to prove the previous identity we have to show that for every $x \in \mathcal{F}_i^{(p+1)}$

$$\lim_{N \to \infty} \mathbb{P}_x \left[ T_{\mathcal{E}_i^{(p+1)}} < T_{\mathcal{E}_i^{(p+1)}} \right] = 0.$$

Since there is no open path from $\mathcal{F}_i^{(p+1)}$ to $\mathcal{E}_i^{(p+1)}$ since by (7.2) the speeded-up blind process $X_i^{N, p}$ converges to the Markov process with rates $\tau_p$ whose recurrent
Observe that the statement of Theorem 2.1. Hence, by Lemma 4.1, we deduce that (7.7) holds, proving claim (7.7).

If follows from the previous considerations that
\[
\lim_{N \to \infty} \frac{\text{cap}_N(E_i^{(p+1)}, E_i^{(p+1)})}{g_N(E_i^{(p+1)}, E_i^{(p+1)})} = \lim_{N \to \infty} \frac{\text{cap}_N(E_i^{(p+1)}, F_i^{(p+1)})}{g_N(E_i^{(p+1)}, E_i^{(p+1)})} \in (0, \infty),
\]
so that
\[
\lim_{N \to \infty} \frac{\text{cap}_N(E_i^{(p+1)}, E_i^{(p+1)})}{\text{cap}_N(E_i^{(p+1)}, F_i^{(p+1)})} = 1.
\]

In consequence, by Lemma 7.8, the following result holds.

**Lemma 7.9.** Fix \(1 \leq i \leq \nu(p+1)\) and \(x \in E_i^{(p+1)}\). The triple \((E_i^{(p+1)}, E_i^{(p+1)} \cup \Delta_{p+1}^0, x)\) is a valley for the trace process \(\eta^N_t, t \geq 0\) of depth \(\theta_{N,i} = \mu_N(E_i^{(p+1)})/\text{cap}_N(E_i^{(p+1)}, E_i^{(p+1)})\). Moreover,
\[
u_{p+1,i} := \lim_{N \to \infty} \frac{g_N(E_i^{(p+1)}, \Delta_{p+1}^0, x)}{\mu_N(E_i^{(p+1)})} \theta_{N,i} \in (0, \infty).
\]

Since the sequences \(g_N(E_i^{(p+1)}, \Delta_{p+1}^0, x)/\mu_N(E_i^{(p+1)}), 1 \leq i \leq \nu(p+1),\) are comparable, repeating the arguments presented in the proof of Proposition 7.8 we deduce the next result.

**Lemma 7.10.** The sequences \(\{\theta_{N,i} : N \geq 1\}, 1 \leq i \leq \nu(p+1)\) are comparable.

Let \(\theta_N(p+1) = \min\{\theta_{N,i} : 1 \leq i \leq \nu(p+1)\}\) and let \(S_{p+1} = \{i : \theta_{N,i} \approx \theta_N(p+1)\}\). Observe that \(\theta_N(p) \prec \theta_N(p+1)\) and that (T5) holds for \(k = p+1\) with this definition.

Denote by \(X^{N,p+1}_t = \Psi_{k/(\theta_{N,p+1})}\) the speeded up blind process introduced in the statement of Theorem 2.1.

**Lemma 7.11.** Condition (T6) holds for \(k = p+1\).

*Proof.* The arguments presented in Section 6 until Lemma 6.3 apply to the present context and show that conditions (T6) are fulfilled for \(k = p+1\).

It remains to prove the convergence of \(X^{N,p+1}_t\). We need to check that the assumptions of [1, Theorem 2.7] are fulfilled. On the one hand, condition (H1) follows from condition (T4) for \(k = p+1\), proved in Lemma 7.4 and from the fact that \(\theta_{N,i} \geq \theta_N(p+1) \succ \theta_N(p)\), proved right after Lemma 7.10 On the other hand, condition (H0) is part of (T3) which has already been proven. \(\square\)

To conclude the recurrence argument, it remains to show that property (T8) holds for \(k = p+1\). We first show that it holds for the trace process \(\eta^N_{t,p}\)

**Lemma 7.12.** For all \(t > 0\),
\[
\lim_{N \to \infty} \max_{x \in E(p)} \mathbb{E}_x^N \left[ \int_0^t 1\{\eta^N_{s,p} \in \Delta_{p+1}^0\} \, ds \right] = 0.
\]
Proof. Since \( \theta_N(p) < \theta_N(p+1) \), a change of variables in the time integral and the Markov property show that for every \( T > 0 \) and for every \( N \) large enough,

\[
E^N_x \left[ \int_0^T 1\{\eta_{s \theta_N(p+1)} \in \Delta^o_{p+1}\} \, ds \right] \leq \frac{2T}{T} \max_{y \in \mathcal{E}^p} E^N_y \left[ \int_0^T 1\{\eta_{s \theta_N(p)} \in \Delta^o_{p+1}\} \, ds \right]
\]

for every \( x \in \mathcal{E}^p \). Note that the process on the right hand side is speeded up by \( \theta_N(p) \) and not by \( \theta_N(p+1) \) anymore.

We estimate the expression on the right hand side of the previous formula. We may, of course, restrict the maximum to \( \Delta^o_{p+1} \). Let \( T_1 \) be the first time the trace process hits \( \mathcal{E}^{(p+1)} \) and let \( T_2 \) be the time it takes for the process to return to \( \Delta^o_{p+1} \) after \( T_1 \):

\[
T_1 = T_{\mathcal{E}^{(p+1)}}, \quad T_2 = \inf \{ s > 0 : \eta_{T_1+s} \in \Delta^o_{p+1} \}.
\]

Fix \( x \in \Delta^o_{p+1} \) and note that

\[
E^N_x \left[ \frac{1}{T} \int_0^T 1\{\eta_{s \theta_N(p)} \in \Delta^o_{p+1}\} \, ds \right] \leq P^N_x[T_1 > t_0 \theta_N(p)] + P^N_x[T_2 \leq T \theta_N(p)] + \frac{t_0}{T}
\]

for all \( t_0 > 0 \). We have proved, in Lemma 7.8 for instance, that the first term on the right hand side vanishes as \( N \to \infty \) and then \( t_0 \to \infty \). By the strong Markov property, the second term is bounded by \( \max_{y \in \mathcal{E}^{(p+1)}} P^N_y[T_{\Delta^o_{p+1}} \leq T \theta_N(p)] \). Since there is no open path from \( \mathcal{E}^{(p+1)} \) to \( \Delta^o_{p+1} \) this probability vanishes as \( N \to \infty \) for all \( T > 0 \). This concludes the proof. \( \square \)

Next result follows from Lemma 7.6 and Lemma 7.12 and concludes the proof of Theorem 7.1.

Corollary 7.13. Condition (T8) holds for \( k = p + 1 \):

\[
\lim_{N \to \infty} \max_{x \in \mathcal{E}} E^N_x \left[ \int_0^T 1\{\eta_{s \theta_N(p+1)} \in \Delta^o_{p+1}\} \, ds \right] = 0.
\]

We conclude this section with a remark. Fix a level \( q \) and denote by \( P_N(x,i,j) \), \( 1 \leq i \neq j \leq \nu(q), x \in \mathcal{E}^i(q) \), the hitting probabilities

\[
P_N(x,i,j) := P^N_x[T_{E^i(q)} = T_{\mathcal{E}^i(q)}]. \quad (7.8)
\]

Recall from Lemma 7.9 that \( \theta_{N,i} = \mu_N(E^{(q)}_i)/\text{cap}_N(E^{(q)}_i, \mathcal{E}^{(q)}_i) \). It follows from Lemma 7.10 with \( q = p + 1 \) that \( \theta_N(q)/\theta_{N,i} \) converges to some number denoted by \( \Lambda(i) \in [0, \infty) \). On the other hand, by Lemma 4.3 \( P_N(x,i,j) \) converges to some \( P(x,i,j) \in [0,1] \). Since by Lemma 7.2 \( E^{(q)}_i, \mathcal{E}^{(q)}_i \cup \Delta^o_{q}, y \in \mathcal{E}^{(q)}_i \), is a valley for the trace process \( \eta^N_{\theta_N(q)} \), it is not difficult to show that the limit \( P(x,i,j) \) does not depend on the starting point \( x \). Therefore, by Lemma 10.2 for any \( 1 \leq i \neq j \leq \nu(q) \),

\[
r^q(i,j) = \lim_{N \to \infty} \theta_{N,i} \lim_{N \to \infty} P^N_x[T_{E^i(q)} = T_{\mathcal{E}^i(q)}]. \quad (7.9)
\]
8. Valleys and Hitting times of the Ising model at low temperature

The proof of Theorem 8.1 follows the strategy presented in the previous sections. As we have seen, the approach relies on the characterization of the shallowest valleys of the model and on the computation of the depths and the hitting times of these valleys. We present in this section the shallowest valleys of the Ising model at low temperature and some estimates of the capacities and the hitting times.

In the present context, a path \( \gamma = (\eta_0, \ldots, \eta_p) \) is a sequence of configuration in \( \Omega \) such that for each \( 0 \leq j < p \), \( \eta_{j+1} = \eta_j^x \) for some \( x \in \Lambda_L \). We shall say that two configurations \( \xi, \eta \) in \( \Omega \) are neighbors if \( \xi = \eta^x \) for some \( x \in \Lambda_L \).

**Lemma 8.1.** Fix a configuration \( \sigma \) in \( \Omega_\sigma \), \( \sigma \neq +1, -1 \). For all \( \beta > 0 \),

\[
G_\beta(\{\sigma\}, \Omega_\sigma) = \begin{cases} 
\mu_\beta(\sigma) e^{-\beta(\ell(\sigma) - 1)h} & \text{if } \ell(\sigma) \leq n_0, \\
\mu_\beta(\sigma) e^{-\beta(2-h)} & \text{otherwise.}
\end{cases}
\] (8.1)

Moreover,

\[
G_\beta((-1), \Omega_{-1}) = \mu_\beta(-1) e^{-\beta(8-3h)}, \quad G_\beta((+1), \Omega_{+1}) = \mu_\beta(+1) e^{-\beta(8+3h)}.
\]

**Proof.** Fix a configuration \( \sigma \) satisfying the assumptions of the lemma and assume that \( \ell := \ell(\sigma) \leq n_0 \). Fix a positive rectangle \( R \) of \( \sigma \) of size \( \ell \times m \) and assume that \( m \geq 3 \). Consider the sequence of configurations \( \sigma = \eta_0, \ldots, \eta_\ell \) obtained by first flipping the spin at a corner of the rectangle \( R \) and then flipping contiguous spins along the smaller side. The last configuration \( \eta_\ell \) is the configuration where the rectangle \( R \) has been replaced by a rectangle \( R' \subset R \) of size \( \ell \times (m-1) \).

The configuration \( \eta_\ell \) belongs to \( \Omega_\sigma \) and the path \( \gamma \) to \( \Gamma_{\{\sigma\}, \Omega_\sigma} \). A simple computation shows that \( \mu_\beta(\eta_{\ell-1}) = \min \{ \mu_\beta(\eta_k) : 0 \leq k \leq \ell \} \) so that \( G_\beta(\{\sigma\}, \Omega_\sigma) \geq G_\beta(\gamma) = \mu_\beta(\eta_{\ell-1}) = \mu_\beta(\sigma) e^{-\beta(\ell-1)h} \).

To prove the reverse inequality, note that the configuration \( \sigma \) has five types of different neighbors \( \sigma^x \). A simple computation shows that \( \mu_\beta(\sigma^x) < \mu_\beta(\sigma) e^{-\beta(\ell-1)h} \) in four cases because \( \ell \leq n_0 < 2/h \). The only type where this inequality does not hold occurs when we flip the spin at a corner of a positive rectangle of \( \sigma \).

To compute \( G_\beta(\{\sigma\}, \Omega_\sigma) \) we need to maximize \( G_\beta(\gamma) \) over all paths \( \gamma \) from \( \sigma \) to \( \Omega_\sigma \). The previous observations shows that the unique possible paths are those where we start flipping the corner of a positive rectangle.

This argument can be iterated. At each step we are only allowed to flip a positive spin which has two negative neighbors. After \( k \) flips we reach configurations of measure \( \mu_\beta(\sigma) e^{-\beta kh} \). Since we are not allowed to pass the level \( \mu_\beta(\sigma) e^{-\beta(\ell-1)h} \), the only configurations in \( \Omega_\sigma \) which can be reached after \( \ell \) flips are the ones where a rectangle \( R \) of length \( \ell \times m \) is replaced by a rectangle \( R' \subset R \) of length \( \ell \times (m-1) \).

The case of a rectangle \( R \) of size \( 2 \times 2 \) is treated in a similar way. In this case, once one corner is removed, the next spins of the square flip at rate one to reach the configuration where the square \( R \) is removed. This proves the lemma in the case \( \ell(\sigma) \leq n_0 \).

Assume now that \( \ell(\sigma) > n_0 \). Consider the path \( \gamma = (\sigma = \eta_0, \ldots, \eta_m) \), where \( \eta_k \) is the configuration obtained from \( \sigma \) by flipping a negative spin contiguous to a positive rectangle, and where \( \eta_{j+1} \) is obtained from \( \eta_j \), \( 2 \leq j < m \), by flipping a negative spin surrounded by two positive spins. The final configuration \( \eta_m \) is reached when no negative spin has two positive neighbors. Clearly, \( \mu_\beta(\eta_k) = \min \{ \mu_\beta(\eta_k) : 0 \leq k \leq m \} \) so that \( G_\beta(\{\sigma\}, \Omega_\sigma) \geq G_\beta(\gamma) = \mu_\beta(\eta_1) = \mu_\beta(\sigma) e^{-\beta(2-h)} \).
A similar argument to the one presented in the first part of the proof of this lemma shows that the path proposed is the optimal one. This concludes the proof of the first part of the lemma.

Consider the the path $\gamma = (\sigma_0 = -1, \sigma_1, \ldots, \sigma_4)$ where $\sigma_j$ is the configuration obtained from $\sigma_{j-1}$, $0 \leq j \leq 3$, by flipping a negative spin from a site with the largest possible number of neighbors with a positive spin. Hence, $\sigma_4 \in \Omega_{-1}$ is obtained from $-1$ by flipping the spins of a $2 \times 2$ square and $G_\beta(\gamma) = \mu_\beta(-1) e^{-\beta(8-3h)}$. In particular, $G_\beta(\{-1\}, \Omega_{-1}) = \mu_\beta(-1) e^{-\beta(8-3h)}$.

To prove the reverse inequality, consider a path $\gamma = (\sigma_0, \ldots, \sigma_p)$ from $-1$ to $\Omega_{-1}$. Let $\sigma_i$ be the first configuration in the path $\gamma$ which has three positive spins. A simple computation shows that $\mu_\beta(\sigma_i) \leq \mu_\beta(-1) e^{-\beta(8-3h)}$. This proves that $G_\beta(\gamma) \leq \mu_\beta(-1) e^{-\beta(8-3h)}$ so that $G_\beta(\{-1\}, \Omega_{-1}) \leq \mu_\beta(-1) e^{-\beta(8-3h)}$, which proves the penultimate assertion of the lemma. The last statement is proved in a similar way.

Recall the definition of the transition probabilities $p(\sigma, \sigma')$, $\sigma \in \Omega_o$, $\sigma' \in S(\sigma)$, introduced in $[31, 33]$. For $\ell(\sigma) = 2$ and $\ell(\sigma) > n_0$, cases where $S(\sigma) = D(\sigma)$, let $q(\sigma, \sigma') = p(\sigma, \sigma')$. For $\sigma \in \Omega_o$, $3 \leq \ell(\sigma) \leq n_0$, $\sigma' \in D(\sigma)$, let $q(\sigma, \sigma')$ be defined by

$$q(\sigma, \sigma') = \frac{1}{|D(\sigma)|}.$$ 

Note that $q(\sigma, \sigma') = p(\sigma, \sigma')$ for $\sigma' \in D(\sigma) \cap S(\sigma) = D(\sigma) \cap \Omega_{\ell(\sigma)}$.

**Lemma 8.2.** Fix a configuration $\sigma$ in $\Omega_o$, $\sigma \neq +1, -1$, and a configuration $\sigma' \in D(\sigma)$. Then,

$$\lim_{\beta \to \infty} P_\beta[T_{\sigma'} = T_{\Omega_o}] = q(\sigma, \sigma').$$

**Proof.** Fix a configuration $\sigma$ satisfying the assumptions of the lemma, a configuration $\sigma' \in D(\sigma)$ and assume that $3 \leq \ell(\sigma) \leq n_0$. Denote by $W(\sigma, \sigma')$ the set of configurations in $W(\sigma)$ which are equal to $\sigma'$ when we flip the positive spin surrounded by three negative spins. Note that $|W(\sigma, \sigma')| = \ell(\sigma)$.

We present the proof for $\ell(\sigma) = 3$, the other cases being analogous. Since $3 = \ell(\sigma) \leq n_0 < 2/h$, we have that $h < 2/3$. For a configuration $\eta$ for which all positive spins are surrounded by at most two negative spins, let $F_1(\eta)$ be the set of all configurations obtained from $\eta$ by flipping a positive spin surrounded by two negative spins.

Let $f_\beta(\eta) = P_\eta[T_{\sigma'} = T_{\Omega_o}]$ and denote by $f$ a limit point of the sequence $f_\beta$, as $\beta \uparrow \infty$. We need to show that $f(\sigma) = 1/|D(\sigma)|$. Since $f_\beta$ is harmonic, a simple computation shows that

$$f_\beta(\sigma) = \frac{1}{|F_1(\sigma)|} \sum_{\xi \in F_1(\sigma)} f_\beta(\xi) + o_1(\beta),$$

where $o_1(\beta)$ is an expression absolutely bounded by $C_0 \exp\{-2\beta[1 - h]\}$ for some finite constant $C_0$ independent of $\beta$ which may change from line to line. It follows from this identity that $f(\sigma) = |F_1(\sigma)|^{-1} \sum_{\xi \in F_1(\sigma)} f(\xi)$.

A similar argument shows that $f(\eta) = f(\sigma)$ for any configuration $\eta$ in $F_1(\sigma)$. Let $F_2(\sigma)$ be the set of configurations obtained from a configuration in $F_1(\sigma)$ by flipping a positive spin surrounded by two negative spins. By the same reasons, $f(\xi) = f(\sigma)$ for any configuration $\xi$ in $F_2(\sigma) \setminus W(\sigma)$. Fix now a configuration $\eta$
in $\mathcal{W}(\sigma, \sigma')$. If $\eta$ differs from $\sigma'$ by a spin in a corner of a positive rectangle of $\sigma$, $f(\eta) = (1/2)[1 + f(\sigma)]$, while if $\eta$ differs from $\sigma'$ by a spin not in a corner, $f(\eta) = (1/3)[1 + 2f(\sigma)]$. For a configuration $\eta$ in $\mathcal{W}(\sigma) \setminus \mathcal{W}(\sigma, \sigma')$, if $\eta$ differs from $\sigma'$ by a spin in a corner of a positive rectangle of $\sigma$, $f(\eta) = (1/2)f(\sigma)$, while if $\eta$ differs from $\sigma'$ by a spin not in a corner, $f(\eta) = (2/3)f(\sigma)$.

Finally, observe that applying the harmonic identity to the terms $f_\beta(\xi)$ in equation (8.2), after some elementary computations we obtain that

$$
\sum_{\xi \in F_1(\sigma)} \sum_{\eta \in F_1(\xi)} \{f_\beta(\eta) - f_\beta(\sigma)\} = o_2(\beta),
$$

where $o_2(\beta)$ is absolutely bounded by $C_0 \{e^{-\beta h} + e^{-\beta[2-3h]}\}$. Since $h < 2/3$, the right hand side vanishes as $\beta \uparrow \infty$ so that $\sum_{\eta \in F_2(\sigma)} \{f(\eta) - f(\sigma)\} = 0$. By the previous identities, this relation is reduced to $\sum_{\eta \in \mathcal{W}(\sigma)} \{f(\eta) - f(\sigma)\} = 0$. From this identity and the explicit values of $f$ in $\mathcal{W}(\sigma)$, we obtain that $f(\sigma) = 1/|\mathbb{D}(\sigma)|$, which proves the lemma.

Suppose now that $\ell(\sigma) = 2 \leq n_0$ and note that equation (8.2) holds. The argument is analogous to the previous one, with one difference. If $\xi \in F_1(\sigma)$ is configuration in which a spin of a $2 \times 2$ positive square $Q$ of $\sigma$ has been flipped, we have that $3f(\xi) = f(\sigma) + f(\eta_1) + f(\eta_2)$, where $f$ is any limit point of the sequence $f_\beta$ and $\eta_1, \eta_2$ are configurations obtained from $\sigma$ by flipping a row or a column of the square $Q$. Iterating the argument based on the harmonicity of $f_\beta$, we conclude that $3f(\xi) = f(\sigma) + 2f(\sigma^*)$, where $\sigma^*$ is the configuration obtained from $\sigma$ by flipping all spins of $Q$.

The proof for $\ell(\sigma) > n_0$ is similar. Observe first that $n_0 = 1$ if $h > 1$. In this case, it is easier to flip a negative spin surrounded by a positive spin than to flip a positive spin surrounded by two negative spins and the proof presented below simplifies. We assume that $h < 1$ so that $n_0 \geq 2$.

Recall the definition of the set $F_1(\sigma)$ introduced in the beginning of the proof. By the harmonic property of $f_\beta$,

$$
f_\beta(\sigma) = \frac{1}{|F_1(\sigma)|} \sum_{\xi \in F_1(\sigma)} f_\beta(\xi) + e^{-2\beta[1-h]} \sum_{\eta \in \mathcal{G}_1(\sigma)} \sum_{\xi \in F_1(\sigma)} \{f_\beta(\eta) - f_\beta(\xi)\} + o(\beta),
$$

where $\mathcal{G}_1(\sigma)$ is the set of configurations obtained from $\sigma$ by flipping a negative spin surrounded by a positive spin and where $o(\beta)$ an expression which vanishes faster than $e^{-\beta[1-h]}$ as $\beta \uparrow \infty$.

We claim that

$$
\lim_{\beta \to \infty} e^{2\beta[1-h]} \sum_{\xi \in F_1(\sigma)} \{f_\beta(\xi) - f_\beta(\sigma)\} = 0. \tag{8.3}
$$

To prove this claim, denote by $F_k(\sigma)$, $1 \leq k \leq n_0$, the configurations obtained from $\sigma$ by successively flipping $k$ distinct positive spins surrounded by two negative spins: $F_{j+1}(\sigma) = \cup_{\xi \in F_j(\sigma)} F_1(\xi)$. Denote by $\mathcal{G}_1(\eta)$ the predecessors of $\eta$, that is, the configurations obtained from $\eta$ by flipping a negative spin surrounded by two positive spins. Hence, $\mathcal{G}_1(\eta) \subset F_{j-1}(\sigma)$ if $\eta$ belongs to $F_j(\sigma)$. By the harmonic property, for every $\eta \in F_j(\sigma)$, $1 \leq j < n_0$,

$$
\sum_{\xi \in \mathcal{G}_1(\eta)} \{f_\beta(\eta) - f_\beta(\xi)\} = e^{-\beta h} \sum_{\zeta \in F_1(\eta)} \{f_\beta(\zeta) - f_\beta(\eta)\} + O(e^{-\beta[2-h]}).$$
Replacing this identity in the sum appearing in [8.3], we reduce the proof of (8.3) to the proof that
\[ e^{2\beta (1-h)} e^{-(n_0-1)\beta h} \sum_{\xi_1 \in F_1(\sigma)} \ldots \sum_{\xi_{n_0} \in F_1(\xi_{n_0-1})} \{ f_\beta (\xi_{n_0}) - f_\beta (\xi_{n_0-1}) \} \]
vanishes as \( \beta \uparrow \infty \). This holds because \( f_\beta \) is bounded by one and \( 2/h < n_0 + 1 \).

By the harmonic property of \( f_\beta \) at \( \xi \in F_1(\sigma) \), \( f(\xi) = f(\sigma) \) for any limit point \( f \) of the sequence \( f_\beta \). Moreover, by [8.3] and by the displayed formula appearing just before (8.3),
\[ \sum_{\eta \in G(\sigma)} [f(\eta) - f(\sigma)] = 0. \]
Recall the notation introduced in Section 3. Note that \( G = G(\sigma) \) and that \( f(\eta) = [j + f(\sigma)]/(j+1) \) if \( \eta \) belongs to \( W_j(\sigma, \sigma') \), \( 1 \leq j \leq 3 \), while \( f(\eta) = f(\sigma)/(j+1) \) if \( \eta \in W_j(\sigma, \sigma') \). This observation permits to conclude the proof of the lemma.

Recall the definition of the sets \( \Omega_{o,k}, 1 \leq k \leq n_0 \), and \( S(\sigma) \) introduced in Section 3.

**Corollary 8.3.** Fix a configuration \( \sigma \) in \( \Omega_{o,k} \setminus \Omega_{o,k+1}, 1 \leq k \leq n_0, \sigma \neq +1,-1 \). Let \( \Omega_{k,\sigma} = \Omega_{o,k} \setminus \{ \sigma \} \). Then, for all \( \sigma' \in \Omega_{k,\sigma} \),
\[ \lim_{\beta \to \infty} P_\beta [T_{\sigma'} = T_{\Omega_{k,\sigma}}] = p(\sigma, \sigma'). \]

**Proof.** Fix \( 1 \leq k \leq n_0 \) and a configuration \( \sigma \) in \( \Omega_{o,k} \setminus \Omega_{o,k+1}, \sigma \neq +1,-1 \). For \( k = 1 \) and \( k = n_0 \), since \( D(\sigma) = S(\sigma) \) and \( \sum_{\sigma' \in D(\sigma)} q(\sigma, \sigma') = 1 \), by Lemma 8.2,
\[ \lim_{\beta \to \infty} P_\beta [T_{\Omega(\sigma)} = T_{\Omega}] = 1. \]
Since \( S(\sigma) \subset \Omega_{k,\sigma} \subset \Omega_{\sigma} \) we may replace \( T_{\Omega(\sigma)} \) by \( T_{\Omega_{k,\sigma}} \) in the previous equation. The corollary follows now from Lemma 8.2 and the fact that \( p = q \) for \( k = 1 \) and \( k = n_0 \).

Consider now the case \( 2 \leq k < n_0 \). Fix a configuration \( \sigma' \in D(\sigma) \cap \Omega_{o,k} \subset S(\sigma) \). Since \( T_{\Omega_{o,k}} \leq T_{\Omega_{k,\sigma}} \), and since \( p(\sigma, \sigma'') = q(\sigma, \sigma''') \) for \( \sigma'' \in S(\sigma) \), by Lemma 8.2,
\[ \lim_{\beta \to \infty} \inf P_\beta [T_{\sigma'} = T_{\Omega_{k,\sigma}}] \geq \lim_{\beta \to \infty} P_\beta [T_{\sigma'} = T_{\Omega_{k,\sigma}}] = p(\sigma, \sigma'). \]

Fix now a configuration \( \sigma' \in S(\sigma) \setminus D(\sigma) \). This configuration is obtained from \( \sigma \) by flipping all spins of a positive \( \ell(\sigma) \times \ell(\sigma) \) square of \( \sigma \). Denote by \( \sigma_j, 1 \leq j \leq 4 \), the four configurations obtained from \( \sigma \) by flipping all spins from one of the sides of this square. Of course,
\[ P_\beta [T_{\sigma'} = T_{\Omega_{k,\sigma}}] \geq \sum_{j=1}^4 P_\beta [T_{\sigma'} = T_{\Omega_{k,\sigma}}, T_{\sigma_j} = T_{\Omega_{k,\sigma}}]. \]
Since \( T_{\Omega_{k,\sigma}} \leq T_{\Omega_{k,\sigma}} \), and \( \sigma_j \notin \Omega_{k,\sigma} \), by the strong Markov property, the right hand side is equal to
\[ \sum_{j=1}^4 P_\beta [T_{\sigma_j} = T_{\Omega_{k,\sigma}}] P_\beta [T_{\sigma'} = T_{\Omega_{k,\sigma}}]. \]
By Lemma 8.2, \( P_\beta [T_{\sigma} = T_{\Omega_{k,\sigma}}] \) converges to \( q(\sigma, \sigma_j) \) as \( \beta \uparrow \infty \). We also claim that \( P_\beta [T_{\sigma'} = T_{\Omega_{k,\sigma}}] \) converges to 1 as \( \beta \uparrow \infty \) for \( 1 \leq j \leq 4 \). Indeed, for a fixed \( j \),
\[ \ell(\sigma_j) = \ell(\sigma) - 1 \] and the configuration \( \sigma_j \) has one and only one positive rectangle \( R \) with a side of length \( \ell(\sigma) - 1 \). It follows from Lemma 8.2 and from the definition of the sets \( D(\sigma^*) \) that the process first flips the spins of one side of the rectangle \( R \) transforming it into a positive \([\ell(\sigma) - 1] \times [\ell(\sigma) - 1]\) square. Then, it flips the spins of one side of this square transforming it into a positive \([\ell(\sigma) - 2] \times [\ell(\sigma) - 1]\) rectangle and so on, until the process reaches a configuration where the initial rectangle \( R \) is transformed into a \( 2 \times 2 \) square, without flipping in this process any other site which is not contained in the original \( \ell(\sigma) \times \ell(\sigma) \) positive square of \( \sigma \). In the last step, all spins of the \( 2 \times 2 \) positive square are flipped and the process reaches the configuration \( \sigma' \) which belongs to \( \Omega_{k,\sigma} \) and is the first one to belong to this set in the evolution just described. This proves the claim.

It follows from this argument that

\[
\liminf_{\beta \to \infty} P_\beta^\sigma[T_{\sigma'} = T_{\Omega_{k,\sigma}}] \geq \sum_{j=1}^4 q(\sigma, \sigma_j) = p(\sigma, \sigma').
\]

Since this inequality holds for all \( \sigma' \in S(\sigma) \) and \( \sum_{\sigma' \in S(\sigma)} p(\sigma, \sigma') = 1 \), the lemma is proved.

The proof of Lemma 8.2 describes the asymptotic behavior of \( P_\eta^\sigma[T_\sigma < T_{\Omega_\sigma}] \) for some configurations \( \eta \), but not for all. We may not, therefore, apply blindly Lemma 4.2 to deduce the limit of the capacity \( \text{cap}_\beta(\{\sigma\}, \Omega_\sigma) \). Next result fills the gaps.

For \( 3 \leq \ell(\sigma) \leq n_0 \), denote by \( \mathcal{W}_1(\sigma) \) the configurations in \( \mathcal{W}(\sigma) \) whose positive spin surrounded by three negative spins is in the corner of a positive rectangle of \( \sigma \) and denote by \( \mathcal{W}_2(\sigma) \) the remaining configurations of \( \mathcal{W}(\sigma) \). Note that configurations in \( \mathcal{W}_1(\sigma) \) jump to \( \Omega_\sigma \) with probability \((j+1)^{-1} + o(\beta)\) and that \(|\mathcal{W}_1(\sigma)| = 4N_r(\sigma) + 8N_s(\sigma), |\mathcal{W}_2(\sigma)| = 2[\ell(\sigma) - 2]N_r(\sigma) + 4[\ell(\sigma) - 2]N_s(\sigma)\).}

**Lemma 8.4.** Fix a configuration \( \sigma \) in \( \Omega_\sigma \), \( \sigma \neq +1, -1 \). If \( 2 \leq \ell := \ell(\sigma) \leq n_0 \),

\[
\lim_{\beta \to \infty} e^{\beta(\ell-1)h} \mu_\beta(\sigma)^{-1} \text{cap}_\beta(\{\sigma\}, \Omega_\sigma) = \theta(\sigma),
\]

and if \( \ell > n_0 \),

\[
\lim_{\beta \to \infty} e^{\beta(2h) - \beta(\ell-1)h} \mu_\beta(\sigma)^{-1} \text{cap}_\beta(\{\sigma\}, \Omega_\sigma) = \theta(\sigma),
\]

where \( \theta(\sigma) \) has been defined in (3.4).

**Proof.** Fix a configuration \( \sigma \) satisfying the assumptions of the lemma and assume that \( 3 \leq \ell := \ell(\sigma) \leq n_0 \). By Lemmas 4.1 and 8.1, we know that \( \text{cap}_\beta(\{\sigma\}, \Omega_\sigma) \) is of order \( \mu_\beta(\sigma)e^{-\beta(\ell-1)h} \).

We start with the proof of the upper bound for the capacity. Recall that we denote by \( \mathcal{W}(\sigma) \) the set of saddle configurations of the valley \( \{\sigma\}, \{\sigma \cup \Delta, \sigma\} \). Denote by \( B \) the set of all configurations \( \eta \) which do not belong to \( \mathcal{W}(\sigma) \) and which can be reached from \( \sigma \) by self-avoiding paths \( \gamma = (\sigma = \eta_0, \eta_1, \ldots, \eta_p = \eta) \) such that \( \mu_\beta(\eta_k) \geq \mu_\beta(\sigma)e^{-\beta(\ell-1)h}, 0 \leq k \leq p \). It follows from the proof of Lemma 8.1 that all these configurations are obtained from \( \sigma \) by successively flipping at most \( \ell - 1 \) positive spins which are surrounded by two negative spins. Note that all neighbors \( \xi \) of a configuration \( \eta \in B \) which do not belong to \( B \) have measure \( \mu_\beta(\xi) < \mu_\beta(\sigma)e^{-\beta(\ell-1)h} \).
Consider the function $f : \Omega \to [0, 1]$ defined as follows. Set $f(\sigma) = 1, f = 1$ on $B$, $f = j/(j+1)$ on $W_j(\sigma)$ and $f = 0$ elsewhere. By definition of capacity and by definition of the function $f$, $\text{cap}_f(\{\sigma\}, \Omega_\sigma) \leq D_\beta(f) = \mu_\beta(\sigma)e^{-\beta[\ell-1]h}\{2/3\}|W_2(\sigma)| + (1/2)|W_1(\sigma)| + o(\beta)$, where $o(\beta) \propto \mu_\beta(\sigma)e^{-\beta[\ell-1]h}$. This proves the upper bound.

To prove the lower bound, consider a function $f$ equal to 1 at $\sigma$ and 0 on $\Omega_\sigma$. Denote by $A_0$ the set of all configurations $\eta$ which can be reached from $\sigma$ by self-avoiding paths $\gamma = (\sigma = \eta_0, \eta_1, \ldots, \eta_\ell = \eta)$ such that $\mu_\beta(\eta_k) \geq \mu_\beta(\sigma)e^{-\beta[\ell-1]h}$, $0 \leq k \leq \ell$, and let $A = A_0 \cup \mathbb{D}(\sigma)$. By definition of the Dirichlet form, $D_\beta(f) \geq \sum_{(\eta, \xi) \in A} \sum_{(\eta, \xi) \in A} G_\beta(\eta, \xi)|f(\xi) - f(\eta)|^2$.

Denote by $f_\beta : A \to [0, 1]$ the function which minimizes the right hand side with the boundary conditions imposed above. It is well known that $f_\beta(\eta) = P^{A,\beta}[T_\sigma < T_{\mathbb{D}(\sigma)}]$ where $P^{A,\beta}$ stands for the probability on the path space induced by the reversible Markov process whose Dirichlet form is the one appearing on the right hand side of the previous formula. The asymptotic behavior of $f_\beta(\eta)$, as $\beta \uparrow \infty$, has been examined in the previous lemma for certain configurations. The arguments presented in the proof of the lower bound of Lemma 8.4 permit to conclude.

The proofs for $\ell(\sigma) = 2 < n_0$ and $\ell(\sigma) > n_0$ are simpler and left to the reader. □

Recall the definition of the set $\Omega_{k,\sigma}$ introduced in Corollary 8.3 and fix $2 \leq k \leq n_0$. Since $\Omega_{k,\sigma} \subset \Omega_\sigma$, $\text{cap}_f(\{\sigma\}, \Omega_{k,\sigma}) \leq \text{cap}_f(\{\sigma\}, \Omega_\sigma)$. The method of the proof of the lower bound for $\text{cap}_f(\{\sigma\}, \Omega_\sigma)$ together with the asymptotic behavior of the hitting times stated in Corollary 8.3 provide the next result.

**Corollary 8.5.** Fix $2 \leq k < n_0$ and a configuration $\sigma$ in $\Omega_{k,\sigma} \setminus \Omega_{k+1,\sigma}$. Then,

$$\lim_{\beta \to \infty} e^{\beta kh} \mu_\beta(\sigma)^{-1} \text{cap}_f(\{\sigma\}, \Omega_{k,\sigma}) = \theta(\sigma).$$

Moreover, for $\sigma$ in $\Omega_{n_0,\sigma} \setminus \Omega_{n_0+1,\sigma}$,

$$\lim_{\beta \to \infty} e^{\beta(2-k)h} \mu_\beta(\sigma)^{-1} \text{cap}_f(\{\sigma\}, \Omega_{n_0,\sigma}) = \theta(\sigma).$$

**9. Proofs of Theorem 3.1 and Theorem 3.2**

The proof of Theorem 3.1 is based on the theory developed in the first sections of this article. A simple computation shows that $H(\sigma^x) - H(\sigma) = \sum_{y:|y-x|=1}\sigma(y)\sigma(x) + h\sigma(x)$, where $|\cdot|$ stands for the Euclidean norm. Since $0 < h < 2$, the jump rates $c(x, \sigma)$ may only assume the values $1, e^{-\beta[4+h]}, e^{-\beta[2+h]}, e^{-\beta h}$ and $e^{-\beta[2-h]}$. Assumptions (2.1), (2.2) are therefore satisfied.

Recall the terminology and the notation introduced in Section 5. According to the theory developed in the previous sections, the first step in the proof of the metastable behavior of a Markov process is the description of the evolution among the shallowest valleys which we now determine. Since a negative (resp. positive) spin surrounded by two (resp. three) positive (resp. negative) spins flips at rate one, it is not difficult to show that the leaves $\mathcal{E}_1, \ldots, \mathcal{E}_\nu$ defined in Section 6 are all the singletons formed by the elements of $\Omega_\sigma$ so that $\nu = |\Omega_\sigma|$ and $\Delta = \Omega \setminus \Omega_\sigma$.

Denote by $\mathcal{E}_\sigma$ the singleton $\{\sigma\}, \sigma \in \Omega_\sigma$. By Lemma 5.4, Proposition 5.7 and Lemma 8.1, $\{\sigma\}, \{\sigma\} \cup \Delta, \sigma, \sigma \neq -1, +1$, is a valley of depth $e^{\beta[\ell(\sigma)-1]h}\theta(\sigma)^{-1}$ if $2 \leq \ell(\sigma) \leq n_0$ and of depth $e^{\beta(2-h)}\theta(\sigma)^{-1}$ if $\ell(\sigma) > n_0$. Moreover, by Lemma 8.1, Lemma 5.1 and the same results invoked above, $\{\pm 1\}, \{\pm 1\} \cup \Delta, \pm 1$, is a valley
whose depth is of order $e^{\beta(8\pm 3h)}$. The exact depth of these latter valleys is not important at this stage.

To describe the evolution among the shallowest valleys, recall the notation introduced in Section 6. For a subset $F$ of $\Omega$, denote by $R^F_\beta(\sigma, \sigma')$, $\sigma, \sigma' \in F$, the jump rates of the trace $\sigma^F_t$ of the process $\sigma_t$ on $F$. Let $r^F_\beta(A, B)$, $A, B \subset F$, $A \cap B = \emptyset$, be the average jump rates of $\sigma^F_t$ from $A$ to $B$:

$$r^F_\beta(A, B) = \frac{1}{\mu_\beta(A)} \sum_{\sigma \in A} \mu_\beta(\sigma) \sum_{\sigma' \in B} R^F_\beta(\sigma, \sigma').$$

In view of the depths of the valleys $\{\{\sigma\}, \{\sigma\} \cup \Delta, \sigma\}$, $\sigma \in \Omega$, the set $S_1$ can be identified to the set $\Omega_{0,1} \setminus \Omega_{0,2}$. Recall that $\theta_\beta(1) = e^{\beta h}$ if $n_0 \geq 2$ and $\theta_\beta(1) = e^{\beta(2-h)}$ if $n_0 = 1$. By Lemma 6.4, Corollary 8.3, the explicit expression for the depth of the valleys obtained above, and Lemma 11.2, the scaled average rates $e^{\beta h} r^F_\beta(\sigma, \sigma')$, $\sigma, \sigma' \in \Omega$, converge to $r(\sigma, \sigma') = \theta(\sigma)p(\sigma, \sigma')$, where $p(\sigma, \sigma')$ and $\theta(\sigma)$ have been introduced in (3.1)--(3.4).

Recall that we denote by $\sigma^\beta_{t,1}$ the trace of the Markov process $\sigma^\beta_t$ on $\Omega_{0,1}$. By Lemma 6.2, with $\theta_\beta(1) = e^{\beta h}$ and by the observations of the previous paragraph, the speeded-up process $\sigma^\beta_{t\theta(1)}$ converges to a Markov process on $\Omega_{0,1}$ with jump rates $r(\sigma, \sigma') = \theta(\sigma)p(\sigma, \sigma')$. By Proposition 6.3, on the time scale $\theta_\beta(1)$ the time spent in $\Delta$ is negligible. This proves Theorem 3.1 for $k = 1$.

The proof of Theorem 3.1 in the longer time scales is based on Theorem 7.1 and follows the strategy presented in Remark 7.2. Recall the notation introduced in Section 7 and Assumption T. Since Theorem 3.1 has been proven for $k = 1$, Assumption T holds at level one because all 1-metastates are singletons.

Theorem 3.1 for $2 \leq k \leq n_0$ follows from Theorem 7.1. As explained in Remark 7.2, we just need to to characterize the metastates at each level, the depth of each valley and the asymptotic rates. This has been done for $2 \leq k \leq n_0$ in Corollary 8.3 and Corollary 8.5 in view of Lemma 11.2. We present in details the case $k = 2$ and leave the rest of the recursive argument to the reader.

Assume that $n_0 \geq 2$. It follows from the dynamics generated by the rates $r$ introduced above that the leaves at level 2, $\mathcal{E}^{(2)}_1, \ldots, \mathcal{E}^{(2)}_{n_0}$, are all the singletons formed by the elements of $\Omega_{0,2}$ so that $\nu(2) = |\Omega_{0,2}|$ and $\Delta_2 = \Omega \setminus \Omega_{0,2}$, $\Delta^2_2 = \Omega_{0,2} \setminus \Omega_{0,3}$.

By Theorem 7.1 with $p = 1$ and Corollary 8.3, the triples $\{\{\sigma\}, \{\sigma\} \cup \Delta^2_2, \sigma\}$, $\sigma \in \Omega_{0,2}$, $\sigma \neq -1, +1$, are valleys for the trace process $\sigma^\beta_{t,1}$ of depth $e^{\beta\ell(\sigma)(1-h)}\theta(\sigma^{-1})$ if $3 \leq \ell(\sigma) \leq n_0$ and of depth $e^{\beta(2-h)}\theta(\sigma^{-1})$ if $\ell(\sigma) > n_0$. Moreover, by Lemma 8.1 and Lemma 11.2, $\{\{\pm 1\} \{\pm 1\} \cup \Delta^2_2, \pm 1\}$ is a valley for the trace process $\sigma^\beta_{t,1}$ whose depth is of order $e^{\beta(8\pm 3h)}$.

Note that the Ising model presents the particularity that the $p$-metastates are 1-metastates, and not a union of 1-metastates.

Recall the definition of the set $S_2$ introduced just after Lemma 7.10. The set $S_2$ can be identified to the set $\Omega_{0,2} \setminus \Omega_{0,3}$. Set $\theta_\beta(2) = e^{\beta h}$ if $n_0 > 2$ and $\theta_\beta(2) = e^{\beta(2-h)}$ if $n_0 = 2$. By Theorem 7.1 with $p = 1$, Lemma 10.2, Corollary 8.3 and Corollary 8.5, $\sigma^\beta_{t,2}$ converges to a Markov process on $\Omega_{0,2}$ with jump rates $r(\sigma, \sigma') = \theta(\sigma)p(\sigma, \sigma')$ introduced in (3.1)--(3.4). Furthermore, by Theorem 7.1 with $p = 1$, on the time scale $\theta_\beta(2)$ the time spent in $\Delta_2$ is negligible. This proves Theorem 3.1 for $k = 2$. \qed
We now turn to the proof of Theorem 3.2. It relies on the following lemma.
Recall the definition of the sets $\mathbb{W}(-1)$, $\mathbb{W}_1(-1)$ and $\mathbb{W}_2(-1)$ and of the number $\theta(-1)$ introduced just before the statement of Theorem 3.2.

**Lemma 9.1.** For $\beta > 0$, $G_\beta\{-1\}, \{+1\} = \mu_\beta(\sigma^*)$, for any $\sigma^* \in \mathbb{W}(-1)$. Moreover,
\[
\lim_{\beta \to \infty} e^{\beta c(h)} \mu_\beta(-1)^{-1} \cap_\beta\{-1\}, \{+1\} = \theta(-1),
\]
where $c(h) = 4(n_0+1)-h[(n_0+1)n_0+1]$ and $\theta(-1) = (2/3)|\mathbb{W}_2(-1)|+(1/2)|\mathbb{W}_1(-1)|$.

**Proof.** The proof of the first assertion is left to the reader. The proof of the second one is similar to the one of Lemma 4.2.

Denote by $B$ the set of all configurations $\eta$ which do not belong to $\mathbb{W}(-1)$ and which can be reached from $-1$ by self-avoiding paths $\gamma = (-1 = \eta_0, \eta_1, \ldots, \eta_p = \eta)$ such that $\mu_\beta(\eta_k) \geq \mu_\beta(\sigma^*)$, $0 \leq k \leq p$, for some $\sigma^* \in \mathbb{W}(-1)$. All these configurations are obtained from $-1$ by flipping at most $n_0(n_0+1)$ negative spins. Note that all neighbors $\xi$ of a configuration $\eta \in B$ which do not belong to $B$ have measure $\mu_\beta(\xi) < \mu_\beta(\sigma^*)$.

Consider the function $f: \Omega \to [0,1]$ defined as follows. Set $f(-1) = 1$, $f = 1/(j+1)$ on $B$, $f = 1/(j+1)$ on $\mathbb{W}_j(\sigma)$ and $f = 0$ elsewhere. By definition of capacity and by definition of the function $f$, $\cap_\beta\{-1\}, \{+1\} \leq D_\beta(\eta, \xi) = \mu_\beta(\sigma^*)\{2/3|\mathbb{W}_2(-1)|+(1/2)|\mathbb{W}_1(-1)|\} + o(\beta)$, where $o(\beta) \prec \mu_\beta(\sigma^*)$. This proves the upper bound.

To prove the lower bound, recall that the function $f: \Omega \to \mathbb{R}$ which minimizes the Dirichlet form under the constraint that $f(-1) = 1, f(+1) = 0$ is the hitting time $g_\beta(\sigma) = \mathbb{P}_0[T_\beta < T_{\beta+1}]$. Denote by $A$ the set of all neighbors $\xi$ of $\mathbb{W}(-1)$ which are obtained from a configuration $\eta \in \mathbb{W}(-1)$ by either flipping the positive spin surrounded by three negative spins or by flipping a negative spin surrounded by two positive spins. By definition of the Dirichlet form,
\[
\cap_\beta\{-1\}, \{+1\} = D_\beta(g_\beta) \geq \sum_{\eta \in \mathbb{W}(-1), \xi \in A} G_\beta(\eta, \xi)(g_\beta(\xi) - g_\beta(\eta))^2.
\]

It follows from Corollary 8.3 that $g_\beta(\xi)$ converges to 0 (resp. 1) as $\beta \uparrow \infty$ if $\xi$ is a configuration obtained from a configuration in $\mathbb{W}(-1)$ by flipping a negative spin surrounded by two positive spins (resp. by flipping the positive spin surrounded by three negative spins). On the other hand, since $g_\beta$ is harmonic and since a configuration $\eta \in \mathbb{W}_j(-1)$ jumps to configurations in $A$, where the asymptotic behavior of $g_\beta$ is known, at rates of order one, and jumps to other configurations at rate $o(\beta)$, $g_\beta(\eta)$ converges, as $\beta \uparrow \infty$, to 1/(j + 1) if $\eta \in W_j(-1)$. This proves the lower bound since $G_\beta(\eta, \xi) = \mu_\beta(\sigma^*)$ for $\eta \in \mathbb{W}(-1), \xi \in A$.

We are now in a position to prove Theorem 3.2 which relies on Theorem 7.1 and the strategy presented in Remark 7.2. Up to this point we proved Assumption T at level $n_0$. In view of the asymptotic dynamics of the trace process $\sigma^{}_{1, n_0}$ described in Theorem 3.1, there are only two $(n_0+1)$-metastates, $\{-1\}$ and $\{+1\}$. By Theorem 7.1 and by Lemma 9.1, $\{-1\} \cup \Delta_{n_0+1}(-1)$ is a valley for the trace process $\sigma^{}_{1, n_0}$ of depth $e^{3c(h)}\theta(-1)^{-1}$. A similar computation to the one presented in Lemma 9.1 shows that $\{+1\} \cup \Delta_{n_0+1}(+1)$ is a valley for the trace process $\sigma^{}_{1, n_0}$ whose depth is of magnitude larger than the one of the valley.
Proof. We need to check the three conditions of [1, Definition 2.1]. Since \( (B_N \cup C_N)^c \subset B_N^c \), condition (V1) is clearly fulfilled.

To prove (V3), decompose the event \( T_{(B\cup C)^c}(\Delta \cup \mathcal{C}) > \delta \theta_N \) according to whether \( T_e < T_{(B\cup C)^c} \) or \( T_e > T_{(B\cup C)^c} \). In the latter case, \( T_{(B\cup C)^c}(\Delta \cup \mathcal{C}) = T_{B^c}(\Delta) \) so that for every point \( \eta = (\eta^N : N \geq 1) \) in \( \mathcal{W} \),

\[
\limsup_{N \to \infty} \mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{(B\cup C)^c} > \delta , T_e > T_{(B\cup C)^c} \right] \leq \lim_{N \to \infty} \mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{B^c}(\Delta) > \delta \right] = 0 ,
\]

where the last identity follows from the fact that the triple \( (\mathcal{W}, \mathcal{B}, \xi) \) is a valley and from condition (V3) in the definition of a valley. On the other hand, since on the
set $T_{\bar{c}} < T_{(B \cup C)^c}$,

$$T_{(B \cup C)^c}(\Delta \cup \varnothing) = \int_0^{T_{\bar{c}}} 1\{\eta_s^N \in \Delta_N \cup C_N\} \, ds + \int_{T_{\bar{c}}}^{T_{(B \cup C)^c}} 1\{\eta_s^N \in \Delta_N \cup C_N\} \, ds$$

$$= \int_0^{T_{\bar{c}}} 1\{\eta_s^N \in \Delta_N\} \, ds + \int_{T_{\bar{c}}}^{T_{(B \cup C)^c}} 1\{\eta_s^N \in \Delta_N \cup C_N\} \, ds,$$

by the strong Markov property,

$$\mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{(B \cup C)^c}(\Delta \cup \varnothing) > \delta, T_{\bar{c}} < T_{(B \cup C)^c} \right] \leq \mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{B^c}(\Delta) > \delta/2 \right]$$

$$+ \sup_{\eta \in C_N} \mathbb{P}_{\eta} \left[ \frac{1}{\theta_N} \int_0^{T(B \cup C)^c} 1\{\eta_s^N \in \Delta_N \cup C_N\} \, ds \right].$$

The right hand side of this inequality vanishes as $N \uparrow \infty$ by hypothesis 10.1 and by the fact that the triple $(W, B, \xi)$ is a valley.

Putting together the two previous estimates, we obtain that for every $\delta > 0$ and every point $\eta = (\eta^N : N \geq 1)$ in $W$,

$$\lim_{N \to \infty} \mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{(B \cup C)^c}(\Delta \cup \varnothing) > \delta \right] = 0.$$

This shows that the triple $(W, B \cup C, \xi)$ satisfies assumption (V3) of a valley with depth $\theta_N$.

It remains to check that the assumption (V2) of a valley is fulfilled. On the one hand, since $T_{(B \cup C)^c} \geq T_{B^c}$ and since the triple $(W, B, \xi)$ is a valley of depth $\theta_N$, for every $t > 0$ and every point $\eta = (\eta^N : N \geq 1)$ in $W$,

$$\liminf_{N \to \infty} \mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{(B \cup C)^c} > t \right] \geq \lim_{N \to \infty} \mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{B^c} > t \right] = e^{-t}. \quad (10.2)$$

On the other hand, decompose the set $\{T_{(B \cup C)^c} > t\theta_N\}$ according to the partition $T_{\bar{c}} < T_{(B \cup C)^c}, \quad T_{\bar{c}} > T_{(B \cup C)^c}$. In the latter set, $T_{(B \cup C)^c} = T_{B^c}$, while in the first one, $T_{(B \cup C)^c} = T_{B^c} + T_{(B \cup C)^c} \circ T_{\bar{c}}$. Therefore, for every $t > 0$ and every point $\eta = (\eta^N : N \geq 1)$ in $W$,

$$\mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{(B \cup C)^c} > t \right] = \mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{B^c} > t, T_{\bar{c}} > T_{(B \cup C)^c} \right]$$

$$+ \mathbb{P}_{\eta^N} \left[ T_{B^c} + T_{(B \cup C)^c} \circ T_{\bar{c}} > t \theta_N, T_{\bar{c}} < T_{(B \cup C)^c} \right].$$

By the strong Markov property, the second term on the right hand side is bounded above by

$$\sup_{\eta \in C_N} \mathbb{P}_{\eta} \left[ T_{(B \cup C)^c} > t \theta_N \right] + \mathbb{P}_{\eta^N} \left[ T_{B^c} > (t - \delta)\theta_N, T_{\bar{c}} < T_{(B \cup C)^c} \right]$$

for every $\delta > 0$. Therefore, in view of the two previous displayed formulas, for every $\delta > 0$,

$$\mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{(B \cup C)^c} > t \right] \leq \mathbb{P}_{\eta^N} \left[ \frac{1}{\theta_N} T_{B^c} > t - \delta \right] + \sup_{\eta \in C_N} \mathbb{P}_{\eta} \left[ T_{(B \cup C)^c} > \delta \theta_N \right].$$

By 10.1, the second term on the right hand side vanishes as $N \uparrow \infty$ for every $\delta > 0$. Since the triple $(W, B, \xi)$ is a valley of depth $\theta_N$, by condition (V2) of a
valley, the first term converges to $e^{-(t-\delta)}$ as $N \uparrow \infty$. Hence, letting $\delta \downarrow 0$ after $N \uparrow \infty$, we obtain that for every $t > 0$ and every point $\eta = (\eta^N : N \geq 1)$ in $W$,

$$
\limsup_{N \to \infty} \mathbf{P}_\eta^N\left[ \frac{1}{\theta_N} T_{(B \cup C)N} > t \right] \leq e^{-t} .
$$

This estimate together with (10.2) shows that the triple $(W, B \cup C, \xi)$ satisfies condition (V2) of a valley with depth $\theta_N$. \qed

Of course, this result is only interesting if the process may jump from $B_N$ to $C_N$.

10.1. The positive recurrent reversible case. We assume from now on that the Markov process $\{\eta^N_t : t \geq 0\}$ is positive recurrent and reversible with respect to its unique invariant probability measure denoted by $\mu_N$.

Fix $N \geq 1$ and a proper subset $F_N$ of $E_N$. Denote by $R^F_N(\eta, \xi)$ the jump rates of the trace of the process $\{\eta^N_t : t \geq 0\}$ on the set $F_N$. We refer to [1, Section 6.1] for a precise definition. For each pair $A, B$ of disjoint subsets of $F_N$, denote by $r_{F_N}(A, B)$ the average rate at which the trace process jumps from $A$ to $B$:

$$
r_{F_N}(A, B) = \frac{1}{\mu_N(A)} \sum_{\eta \in A} \mu_N(\eta) \sum_{\xi \in B} R^F_N(\eta, \xi) .
$$

We claim that

$$
r_{F_N}(A, B) \leq \frac{\text{cap}_N(A, B)}{\mu_N(A)} ,
$$

where $\text{cap}_N(A, B)$ stands for the capacity between $A$ and $B$ for the process $\{\eta^N_t : t \geq 0\}$. Indeed, denote by $R^{A \cup B}$ the jump rates of the trace of $\{\eta^N_t : t \geq 0\}$ on $A \cup B$. By [1, Corollary 6.2], $R^{A \cup B}(\eta, \xi) \geq R^F_N(\eta, \xi)$ for every $\eta, \xi \in A \cup B, \eta \neq \xi$. Hence, by definition of the average rates and by [1, Lemma 6.7],

$$
r_{F_N}(A, B) = \frac{1}{\mu_N(A)} \sum_{\eta \in A} \mu_N(\eta) \sum_{\xi \in B} R^F_N(\eta, \xi) \leq r_{A \cup B}(A, B) = \frac{\text{cap}_N(A, B)}{\mu_N(A)} ,
$$

which proves (10.3).

Fix a finite number of disjoint subsets $E_N^1, \ldots, E_N^N$, $\kappa \geq 2$, of $E_N$: $E_N^x \cap E_N^y = \emptyset$, $x \neq y$. Let $E_N = \bigcup_x \overline{E_N^x}$ and let $\tilde{E}_N^x := E_N \setminus E_N^x$.

Denote by $r_{E_N}(\tilde{E}_N^x, \tilde{E}_N^y)$ the average rates $r_{E_N}(\tilde{E}_N^x, \tilde{E}_N^y)$. The next result shows that if the average rates appropriately rescaled converge, their limit can be expressed in terms of the depth of the metastates and their hitting probabilities.

Denote by $\Lambda_N(x)$, $1 \leq x \leq \kappa$, the inverse of the depth of a metastate and by $P_N(\eta, x, y)$, $1 \leq x \neq y \leq \kappa, \eta \in E_N^x$, the hitting probabilities among metastates:

$$
\Lambda_N(x) := \frac{\text{cap}_N(\tilde{E}_N^x, \tilde{E}_N^x)}{\mu_N(\tilde{E}_N^x)} , \quad P_N(\eta, x, y) := \mathbf{P}_\eta[T_{\tilde{E}_N^y} = T_{\tilde{E}_N^x}] .
$$

Lemma 10.2. Suppose that for each $1 \leq x \leq \kappa$ there exists a point $\xi_x = (\xi_x^N : N \geq 1)$ in $E_x^x$ such that the triple $(\tilde{E}_N^x, \tilde{E}_N^x \Delta \Delta, \xi_x)$ is a valley of depth $\mu_N(\tilde{E}_N^x)/\text{cap}_N(\tilde{E}_N^x, \tilde{E}_N^x)$ and such that

$$
\lim_{N \to \infty} \sup_{\eta \in \tilde{E}_N^x} \frac{\text{cap}_N(\tilde{E}_N^x, \tilde{E}_N^x)}{\text{cap}_N(\xi_x^N, \eta)} = 0 .
$$
Suppose, furthermore, that there exists a sequence \((\theta_N : N \geq 1)\) for which the mean rates, the depth and the jump probabilities converge: For any \(1 \leq x \neq y \leq \kappa\) and any sequence \((\eta^N : N \geq 1)\) in \(E^x\),
\[
\lim_{N \to \infty} \theta_N \Lambda_N(x) = \Lambda(x), \quad \lim_{N \to \infty} P_N(\eta^N, x, y) = P(x, y) \quad \lim_{N \to \infty} \theta_N r_N(E^x, E^y) = r(x, y).
\]

Then, \(r(x, y) = \Lambda(x) P(x, y)\).

**Proof.** Note that we assumed that the limit \(P(x, y)\) does not depend on the sequence \((\eta^N : N \geq 1)\).

It follows from \([11,\text{ Theorem 2.7}]\) that for any \(1 \leq x \leq \kappa\) and any sequence \((\eta^N : N \geq 1)\) in \(E^x\), under the measure \(P_{\eta^N}\) the speeded-up process \(X^N_t = \Psi(\eta^N_{\tau^N_t})\) converges to a Markov process on \(\{1, \ldots, \kappa\}\) with jump rates \(r(y, z)\) starting from \(x\). In particular, if we denote by \(\tau^N_t\) the time of the first jump of \(X^N_t\), \(\tau^N_1\) converges to an exponential time of rate \(\lambda(x) = \sum_{y \neq x} r(x, y)\) and \(X^N_{\tau^N_1}\) converges to a random variable with distribution \(p(y) = r(x, y)/\lambda(y)\).

On the other hand, since the triple \((E^x, E^x \cup \Delta, \xi^x)\) is a valley of depth \(\Lambda_N(x)^{-1}\), \(\tau^N_1 \Lambda_N(x)\) converge to a mean one exponential time so that \(\Lambda(x) = \lambda(x)\). Moreover, \(P_{\eta^N}[X^N_{\tau^N_1} = y] = P_{\eta^N}[T_{E^y} = T_{E^x}]\) converges to \(P(x, y)\) so that \(P(x, y) = p(y)\), which proves the lemma.
