Department of Microbiology and Graduate Program of Molecular Medicine, Ajou University School of Medicine, Suwon 442-749, Korea

T cell immunoglobulin mucin domain (TIM)-3 is an immunomodulatory molecule and upregulated in T cells by several cytokines. TIM-3 also influences mast cell function but its transcriptional regulation in mast cells has not been clarified. Therefore, we examined the transcript level and the promoter activity of TIM-3 in mast cells. The TIM-3 transcript level was assessed by real-time RT-PCR and promoter activity by luciferase reporter assay. TIM-3 mRNA levels were increased in HMC-1, a human mast cell line by TGF-β1 stimulation but not by stimulation with interferon (IFN)-α, IFN-λ, TNF-α, or IL-10. TIM-3 promoter −349 to +144 bp region relative to the transcription start site was crucial for the basal and TGF-β1-induced TIM-3 promoter activities in HMC-1 cells. TIM-3 promoter activity was increased by overexpression of Smad2 and Smad4, downstream molecules of TGF-β1 signaling. Our results localize TIM-3 promoter activity to the region spanning −349 to +144 bp in resting and TGF-β1 stimulated mast cells.

INTRODUCTION

T cell immunoglobulin mucin domain (TIM)-3 is expressed in various leukocyte subpopulations and modulates their functions (1). It is expressed on the surfaces of exhausted T cells and involved in the downregulation of effector function of T cells (2-4). TIM-3 on dendritic cells promotes the uptake of apoptotic cells via interaction with phosphatidylserine but suppresses the immunogenicity of nucleic acid via interaction with HMGB1 (5,6). TIM-3 expression in mast cells influences cytokine production and apoptosis of these cells (7). However, the regulation of TIM-3 expression has not been well known.

Mast cells play a significant role in various immune responses. These cells lead allergic symptoms through secretion of mediators and cytokines upon cross-linking of FcεRI (8). Mast cells contribute defense against pathogen: mice devoid of mast cells die from infection that does not result in death in wild type mice (9). Protective immunity is enhanced by mast cell production of TNF-α and recruitment of neutrophils to the infectious site (9). Mast cells are also required for the development of collagen-induced rheumatoid arthritis and the induction of tolerance to skin graft (10,11).

To understand the regulation of TIM-3 expression in mast cells, we investigated the effect of various cytokines on TIM-3 transcription and the activity of TIM-3 promoter in relation with TGF-β1 stimulation of mast cells.

MATERIALS AND METHODS

Reagents

IFN-α, IFN-λ, TGF-β1, IL-10, and TNF-α were purchased from R&D Systems (Minneapolis, MN, USA). Expression vectors for Smad2 and Smad4 were kindly provided by Dr. Cho (Dept. Biochemistry, Ajou University School of Medicine, Korea).

Received on September 4, 2012. Revised on September 19, 2012. Accepted on September 21, 2012.

TIM-3 Promoter Activity in Mast Cells
Jung Sik Kim, et al.

Cell culture
HMC-1, a human mast cell line, was kindly provided by Professor Hyung Min, Kim (Kyunghee University, Suwon, Korea). HMC-1 cells were maintained in IMDM supplemented with 10% FBS, penicillin-streptomycin (each 100 U/ml, 100 ug/ml). Similarly, HEK293 cells were maintained in RPMI 1640 (Gibco BRL, Paisley, Scotland) supplemented with 10% FBS.

Real-time RT-PCR
The total RNA was isolated using RNA STAT-60 (Tel-Test, IN C., Friendwood, TX, USA) and reverse transcribed using Superscriptase II (Invitrogen, Carlsbad, CA, USA). Real-time PCR was performed using primers (5’-TCCAAGGTGCTTACCAGTGC-3’, 5’-GGAATGTGGATATTGGTTAGATT-3’) and a Taq Man probe (5’-ACATGGCCAGGACGACGAC-3’) for TIM-3 transcript which was normalized to GAPDH transcript levels.

RESULTS
TIM-3 transcription was upregulated in HMC-1 cells by TGF-β1 stimulation
In recent studies, TIM-3 mRNA and protein expression levels were up regulated in TGF-β1 stimulated- human mast cells (12) but the transcriptional regulation of TIM-3 by other stimulants has not been well explored. To address this issue a human mast cell line, HMC-1 cells were treated with various cytokines for the indicated time and then TIM-3 mRNA levels were determined by real-time RT-PCR. TIM-3 mRNA expression was not significantly enhanced by treatment with the indicated concentration of IFN-α, IFN-λ, IL-10, or TNF-α (p>0.05) but was significantly increased by TGF-β1 stimulation of HMC-1 cells for 4 h (p<0.005) (Fig. 1).
TIM-3 promoter activity in Mast Cells

Figure 2. Basal TIM-3 promoter activity in HEK293 and HMC-1 cells. (A) Luciferase reporter vectors containing various length of TIM-3 promoter region. (B) HEK293 (5 × 10⁵) or (C) HMC-1 (1 × 10⁶) cells were transfected with the indicated luciferase reporter vector together with pEGFP-N1 vector (1/10 of total plasmid) and 48 h later luciferase activity was measured and normalized to the frequencies of GFP-expressing cells. Relative luciferase activity to control (pGL-Basic) was presented. The data are the mean ± standard deviation of 5 experiments. *p < 0.01.

**TIM-3 promoter activity was increased in HMC-1 cells by TGF-β1 stimulation**

To know the TIM-3 promoter is responsive to TGF-β1 stimulation, we first examined the basal activity of TIM-3 promoter by luciferase reporter assay using vectors depicted in Fig. 2A. Luciferase activities in both HEK293 cells and HMC-1 cells transfected with T3U(0.5)-luc that contains proximal TIM-3 promoter were significantly higher than that of controls transfected with the empty vector pGL-Basic (Fig. 2B and C). Also, luciferase activities driven by T3U(1.0)-luc and T3U(1.8)-luc, respectively were significantly higher than that of controls but lower than that driven by T3U(0.5)-luc. These results indicate that the proximal TIM-3 promoter spanning from +144 to −349 may consist of sufficient element for the basal level transcription of TIM-3 in HMC-1 cells.

We next analyzed the TIM-3 promoter activity in the presence of TGF-β1 stimulation (Fig. 3). Luciferase activity driven by each luciferase reporter vector in the presence of TGF-β1 was presented as fold induction relative to that in the absence of TGF-β1. Luciferase activity in HMC-1 cells transfected with T3U(0.5)-luc or T3U(1.8)-luc was significantly increased (2.3 and 2.6 fold, respectively) by TGF-β1 stimulation compared to that in the absence of TGF-β1 stimulation (p < 0.001). However, luciferase activity in HMC-1 cells transfected with T3U(1.0)-luc or the empty pGL-Basic was not significantly increased by TGF-β1 stimulation compared to that in the absence of TGF-β1 stimulation (p > 0.01). These results suggest that TIM-3 promoter region may contain the TGF-β1 responsive elements.

**TIM-3 promoter activity was upregulated by Smad2 and Smad4 overexpression**

To support the TGF-β1 responsiveness of the TIM-3 promoter, we assessed TIM-3 promoter activity in the cells overexpressing Smad2 and Smad4 that were reported to be involved in the gene expression induced by TGF-β1 (13,14). Given that TGF-β responsive promoter activity was increased by overexpression of either Smad2 or Smad3 in HEK293 cells even in the absence of TGF-β1 stimulation (15), we analyzed TIM-3 promoter activity in HEK293 cells overexpressing...
Smad2 and/or Smad4 without TGF-β1 treatment (Fig. 4). Compared to control, luciferase activity was significantly increased in HEK293 cells by overexpression of Smad2, Smad4 or both (4.5, 5.8 and 11 fold, respectively) (p<0.01). These results imply that TIM-3 promoter region may respond to TGF-β1 stimulation through Smad2 and Smad4 involvement.

DISCUSSION

In this study, we revealed that TIM-3 mRNA expression in a human mast cell line was increased by TGF-β1 stimulation but not by other stimuli such as interferon α and λ, TNF-α, and IL-10. TGF-β1 affects mast cell survival and functions, TGF-β1 inhibits IL-3-dependent mast cell proliferation and counterbalances the effect of IL-4 on mast cell survival, migration, and FcεRI expression (16,17). Also TGF-β1 can elicit mouse mast cell protease-1 expression (18) and mast cell tryptase expression in experimental emphysema model (19). Furthermore, TGF-β1 in both soluble and regulatory T cell-surface bound forms can escalate IL-6 production by mast cells (20). Our results (21) and the previous report by Wiener et al. (12) add another one to the effects of TGF-β1 on mast cells i.e., induction of TIM-3 expression. Except the report by Nakae et al. (7) that TIM-3 cross-linking by an anti-TIM-3 polyclonal Ab can promote IL-4, IL-6 and IL-13 production but suppress mast cell apoptosis, little information is currently available regarding the role of TIM-3 in mast cell function.

We also demonstrated that TIM-3 promoter −349 ~ +144 bp region relative to the transcription start site was crucial for the basal and TGF-β1-induced TIM-3 transcription in HMC-1 cells. Since T3U(0.5)-luc driven luciferase activity in HMC-1 cells was greater than that driven by T3U(1.8)-luc or T3U(1.0)-luc, the DNA fragment of −349 ~ +144 bp seems to contain elements for basal transcription of TIM-3. Compatible to our results, Zhang et al. (22) reported that the basal TIM-3 promoter activity is localized to the region spanning −241 to +63 bp in Y7 cells, a T/NK cell line. Apparently incompatible with our previous observation that TIM-3 promoter activity driven by the −1,362 to +144 bp region was not enhanced by TGF-β1 stimulation (21), luciferase activities under TIM-3 promoter −349 ~ +144 bp region and −1,677 ~ +144 was significantly increased in HMC-1 cells by TGF-β1 stimulation (Fig. 3). Interestingly, the luciferase activity under TIM-3 promoter −872 ~ +144 was not significantly elevated by TGF-β1 stimulation in the present study. Further study is required to investigate whether TIM-3 promoter −1,362 to −350 bp region may contain the element hindering the TGF-β1 responsiveness of TIM-3 promoter −349 ~ +144 bp region.

We showed that overexpression of Smad2 and Smad4 upregulated TIM-3 promoter activity in HEK293 cells, Smad2 and Smad4 are downstream signaling molecules and transcription factors of TGF-β1 signaling (13,14). Although there are three predicted Smad binding elements in TIM-3 promoter −β1 −349 ~ +144 bp region, further study should be followed to clarify whether Smad2 and Smad4 are directly bound to TIM-3 promoter or indirectly involved in TIM-3 transcription in TGF-β1 stimulated mast cells. In T cells, it was reported that two transcription factors regulated TIM-3 transcription in different modes, T-box transcription factor T-bet increases Tim-3 transcription via its interaction with Tim-3 promoter of mouse TH1 cells at approximately 400 bp upstream of the first ATG, whereas signal transducer and activator of transcription (STAT)-4 dose not bind to the Tim-3 promoter but reduces Tim-3 expression in murine T cells when it is knocked-out (23). At present, critical role of MEK, another downstream signaling molecule of TGF-β1 signal pathway, in TIM-3 induction is revealed in HMC-1 cells stimulated with TGF-β1 (21).

Conclusively, our results localize TIM-3 promoter activity in resting and TGF-β1 stimulated HMC-1 cells to the region from −349 to +144 bp relative to the transcription start site and propose a possible regulatory role of Smad2 and Smad4.
in TIM-3 transcription of mast cells.
