Background: Androgen receptor (AR) is the principle therapeutic target in prostate cancer.

Result: We have established that Usp12 deubiquitimates and stabilizes the AR resulting in increased transcriptional and pro-proliferative activity.

Conclusion: We have identified Usp12 to be a novel positive regulator of AR.

Significance: Usp12 presents a therapeutic target upstream of AR that could enable bypassing the limitations of therapeutics aimed specifically at AR.

The androgen receptor (AR), a member of the nuclear receptor family, is a transcription factor involved in prostate cell growth, homeostasis, and transformation. AR is a key protein in growth and development of both normal and malignant prostate, making it a common therapeutic target in prostate cancer. AR is regulated by an interplay of multiple post-translational modifications including ubiquitination. We and others have shown that the AR is ubiquitinated by a number of E3 ubiquitin ligases, including MDM2, CHIP, and NEDD4, which can result in its proteosomal degradation or enhanced transcriptional activity. As ubiquitination of AR causes a change in AR activity or stability and impacts both survival and growth of prostate cancer cells, deubiquitination of these sites has an equally important role. Hence, deubiquitinating enzymes could offer novel therapeutic targets. We performed an siRNA screen to identify deubiquitinating enzymes that regulate AR; in that screen ubiquitin-specific protease 12 (Usp12) was identified as a novel positive regulator of AR. Usp12 is a poorly characterized protein with few known functions and requires the interaction with two cofactors, Uaf-1 and WDR20, for its enzymatic activity. In this report we demonstrate that Usp12, in complex with Uaf-1 and WDR20, deubiquitimates the AR to enhance receptor stability and transcriptional activity. Our data show that Usp12 acts in a pro-proliferative manner by stabilizing AR and enhancing its cellular function.

The androgen receptor (AR)3 belongs to the nuclear hormone receptor superfamily and plays a key role in the transcriptional regulation of numerous genes important in the development of both normal and malignant prostate (1). Ligand binding of the AR in the cytoplasm results in dimerization, translocation to the nucleus, and transcription of androgen-responsive genes. Deregulation of AR signaling leads to the development of prostate cancer (PCa), and as such the receptor represents the most common therapeutic target in PCa (1). The current clinical strategies in PCa revolve around anti-hormone therapies and aim to pharmacologically decrease serum androgen levels. This is currently achieved through the use of luteinizing hormone-releasing hormone agonists such as goserelin or anti-androgens which can be either steroidal (cyproterone acetate) or nonsteroidal (flutamide) and function by competitively inhibiting the AR (2). However, despite initial success most of anti-androgen therapies will invariably fail resulting in castrate-resistant prostate cancer (CRPCa). Importantly, the AR signaling cascade remains functional in CRPCa. Treatment failure can be caused by changes in AR signaling, including alterations in AR cofactor levels and activity as well as emergence of AR mutations that permit receptor activity in the presence of non-androgenic steroids and anti-androgens (2). In CRPCa, AR still remains a crucial target, with increased AR levels and gene amplification observed in 30% of patients. Increased levels of the downstream gene prostate-specific antigen (PSA) in the serum are also associated with PCa recurrence (3). Previous research demonstrated that even at CRPCa stage, depletion of AR by siRNA treatment decreased tumor growth. Similarly, AR overexpression in PCa xenograft in castrate animals still enhanced cancer growth (4).

AR function and activity are known to be regulated by a number of post-translational modifications. In response to androgens, AR is phosphorylated by kinases including AKT (5) and TFIH (6), resulting in changes to transcriptional activity and cellular localization. This can be reversed by phosphatases such as protein phosphatases 1 and 2A (7). Acetylation by p300 (8) and Tip60 (9) enhances transcriptional activity which can be reversed by the histone deacetylases HDAC1 (10) and SIRT1 (11). AR is also subjected to SUMOylation by PIAS1 and PIASxα, a process that is believed to decrease its transcriptional activity (12). We and others have shown that the AR is also...
Usp12 Is a Novel Positive Regulator of the AR

ubiquitinated by a number of E3 ubiquitin ligases, including MDM2 (13, 14), CHIP (15, 16), and NEDD4 (17, 18) which results in proteosomal degradation. AR ubiquitination can also lead to the increase in transcriptional activity; RNF6 has been reported to ubiquitinate AR at Lys-845 and Lys-847, promoting its activity by allowing ARA54 co-activator recruitment (19). Further details of AR post-translational modifications have been recently reviewed (20).

Ubiquitination of AR causes a change in AR activity and stability and impacts both survival and growth of PCa cells. As a result deubiquitination of those sites has an equally important role.

Currently, very little is known about the enzymes that deubiquitinate AR. It has been reported that Usp26 can directly bind and deubiquitinate AR, acting as a co-regulator of AR by reversing AR activation and degradation by MDM2 ubiquitination depending on cellular context (21). Additionally, Usp10 has been reported to bind AR, resulting in increased transcriptional activity (22).

In this study we focused on Usp12, a deubiquitinating enzyme identified in an siRNA screen as a positive regulator of AR. Usp12 has three reported targets; histones H2B, H2A (23), and nonactivated Notch (24). Usp12 is highly homologous to Usp46 and Usp1, and its activity, similar to that of Usp46, is enhanced by binding to its cofactors Uaf-1 and WDR20, with Uaf-1 required for enzymatic activity of Usp12 (25–27). It has been reported that Uaf-1 binds and stabilizes Usp12, and this complex is bound by WDR20. This interaction is both stoichiometric and evolutionarily conserved and has been shown to play the same role in *Schizosaccharomyces pombe* (28). Usp12 and Uaf-1-containing complex was shown to deubiquitinate all types of ubiquitin chains apart from linear chains (27). Our search of Oncomine profiles revealed that Usp12 is differentially expressed in bladder, brain, CNS, cervical, kidney, lymphoma, and ovarian cancer samples compared with healthy controls.

We now show that Usp12, in complex with Uaf-1 and WDR20, interacts with and deubiquitinates the AR resulting in increased protein stability and transcriptional activity. Moreover, we report that Usp12 depletion reduces PCa cell proliferation and up-regulates cell apoptosis, suggesting that it is an additional regulator of the AR that may represent a novel target for therapy.

**EXPERIMENTAL PROCEDURES**

*Antibodies and Plasmids*—Antibodies used were anti-FLAG (Sigma), anti-Usp12 (Dundee Cell Products), anti-AR (Santa Cruz Biotechnology; N20 clone), anti-HA (Santa Cruz Biotechnology; Y11 clone), anti-α-tubulin (Sigma), and anti-ubiquitin (Santa Cruz Biotechnology). Plasmids used were pPSA-Luc, pARE3-luc, pCMV-β-gal, pFLAG-His-AR (9), pFLAG-Usp12 wild type, and C48A mutant generated by *in vitro* mutagenesis (QuickChange; Stratagene), pHA-ubiquitin and pHA-FLAG-WDR20 and pFLAG-Uaf-1 (25, 26), which were kind gifts from Professor Alan D’Andrea (Dana-Farber Cancer Institute, Boston).

*Cell Culture, Transfections, and Reporter Assays*—LNCaP, HEK293T, and COS-7 cells were obtained from American Type Culture Collection (Manassas, VA). VCaP cells were kindly donated by Professor Guido Jenster (Erasmus Medical Centre, Rotterdam). Cells were cultured in RPMI 1640 medium with 2 mM l-glutamine (Invitrogen) supplemented with 10% (v/v) fetal calf serum (FCS) at 37 °C in 5% CO2. LNCaP-A1 variant cell line was derived in-house by culturing LNCaP cells in steroid-depleted medium (DCC) to allow for the development of androgen independence (30). LNCaP-7B7 cells stably overexpressing pPSA-Luc vector were kindly donated by Professor Jan Trapman (Erasmus Medical Centre) and cultured with the addition of 25 μg/ml zeocin. Transfections were performed using TransIT-LT1 reagent (MirusBiol) following the manufacturer’s instructions.

For luciferase assays, cells were transfected with 50 ng of pARE3-luc, 50 ng of pCMV-β-gal, and 10 ng of pFLAG-His-AR, pFLAG-Usp12, and pFLAG-Uaf-1 as required. All reactions were balanced with pCMV empty vector. Cells were cultured under steroid-depleted conditions for 48 h followed by supplementation with dihydrotestosterone (DHT), at a range of concentration of 5 and 10 nM with comparable results obtained for both concentrations, for an additional 24 h. Cells were lysed and incubated in 1 × Promega luciferase assay reagents according to the manufacturer’s instruction, and luciferase counts/s were established and normalized to β-galactosidase activity. Results were normalized to AR expression alone in steroid-depleted conditions.

**siRNA Gene Silencing and Gene Expression Analysis**—The generation and DUB siRNA screening methodology for AR regulators screen using an ELISA against PSA protein as a readout of AR activity in LNCaP cells have been described previously (29). Usp12 targeting siRNA sequences were: (A) GAAACUC-UGUGCAUGUAU[dTdT], (B) CAGAUCUUCCAUAGCAU[dTdT], and (C) CAUCAAGAUUCUAAAGAA[dTdT]; WDR20 was silenced with siRNAs (A) CGAGAAAGAUCAC-AAGCGA[dTdT] and (B) GGUGAAGCUUAAUACCAC-U[dTdT] and Uaf-1 with (A) CAANUUUGUUUCAGUAGA[dTdT] and (B) CAUCAUGACCUAAGAUA[dTdT]. Initial DUB screen used a pool of siRNAs against Usp12, and further experiments were performed using siRNA (B). Uaf-1 A achieved 61.5% knockdown with Uaf-1 B 61% similarly, WDR20 A achieved 67.4% and WDR20 B 57.4% in quantitative PCR (qPCR) validation (data not shown). As a result siRNAs (A) were selected for silencing of both Uaf-1 and WDR20.

LNCaP cells were reverse transfected with siRNA using RNAiMax (Invitrogen) according to the manufacturer’s instructions and incubated in culture medium for 96 h prior to cell lysis and analysis by Western blotting as described previously (31) or qPCR. For qPCR RNA was extracted using the EZ RNA isolation kit (Biological Industries), and cDNA synthesis and data analysis were performed as described previously (32). Proliferation was measured by cell counting 96 h after gene silencing. To measure colony-forming ability cells were reverse transfected with siRNA for 72 h, followed by reseeding at varying cell densities and incubated for 14 days to allow colony formation and stained with crystal violet. Colonies were counted and the surviving fraction calculated (31).

**Flow Cytometry**—Cell cycle profiles were generated by propidium iodide (PI) staining, cells were permeabilized with 1% Triton X-100 and incubated with 1 μg/ml RNaseA and PI fol-
ollowed by analysis on FACSscan (BD Biosciences) (33). Levels of apoptosis were analyzed after 96 h of gene silencing by annexin V assay (BD Biosciences) according to the manufacturer’s instructions and analyzed on a FACSscan. Cells were stained for both annexin V and PI positivity and during analysis divided into quadrants representing normal cells, necrotic cells, and apoptotic cells.

**Immunoprecipitations (IPs)—**Cells were seeded at 5 × 10⁵ cells/90-mm dish, transfected 24 h later with 1 μg of each plasmid as indicated, incubated for 48 h, and lysed directly into lysis buffer (50 mM Tris, pH 7.5, 150 mM NaCl, 0.2 mM Na₃VO₄, 1% Nonidet P-40, 1 mM PMSF, 1 mM DTT, and 1 × protease inhibitors (Roche Applied Science)). Lysates were incubated with 1 μg of antibodies as indicated for 16 h at 4 °, and antibodies were pulled down using protein G-Sepharose beads. For denaturing IPs, cells were subject to 20 μM MG132 proteosomal inhibitor treatment for the final 16 h followed by collection into lysis buffer with an addition of 2% SDS and denatured at 100 °C for 10 min (29). After denaturation samples were diluted 10× in lysis buffer without SDS and processed as in native IP. Immunoprecipitants were analyzed using Western blotting.

Chromatin immunoprecipitations (ChIPs) were performed as described previously (10). LNCaP cells were transfected in steroid-depleted medium for 72 h followed by DHT treatment for 120 min. Data are presented as percentage input using the following formula: % input = 100 × 2ⁿ (CT adjusted input sample – CT immunoprecipitated sample). CT refers to cycle threshold.

**Immunohistochemistry—**Tissue microarray containing 0.6-mm cores of benign prostatic hyperplasia (n = 7), PCa (n = 7), and control tissues including breast, kidney, placenta, ovary, and liver was used. Antibodies were retrieved by pressure cooking the tissue microarray in 0.01 M citrate buffer, pH 6.0, followed by staining the tissues with rabbit polyclonal anti-Usp12 antibody (Dundee Cell Products) (29).

**RESULTS**

**Identification of Usp12 as a Positive Regulator of AR—**To identify DUBs that regulate AR we conducted an siRNA screen in LNCaP cells using an ELISA detecting the levels of PSA, which is an AR target gene product, and as such its levels will be affected by any change in AR activity, as a surrogate readout of AR activity. All samples were normalized against the scrambled control (SCR), and readouts of ±2-fold PSA protein level compared with SCR were taken for further validation. To confirm that target DUBs regulate AR transcriptional activity and not only PSA secretion, further validation included the assessment of PSA mRNA levels upon DUB depletion, eliminating DUBs that solely affect PSA rather than AR activity. Of the 78 screened DUBs, four were identified as potentially involved in androgen-dependent regulation of AR. Silencing of one of the targets, Usp12, resulted in 73% reduction in PSA protein levels (Fig. 1A, highlighted panel). This result was also confirmed by Western blotting (Fig. 1B). Usp12 siRNA was shown to significantly decrease Usp12 transcript levels in three PCa cell lines, namely, LNCaP, LNCaP-AI, and VCaP (Fig. 1C). Additionally, depletion of Usp12 resulted in significant decrease of PSA transcript in LNCaP, LNCaP-AI, and VCaP cells, confirming that Usp12 affects AR transcriptional activity and as a result PSA gene expression rather than protein secretion (Fig. 1C). To summarize, Usp12 has been identified as a positive regulator of AR in multiple PCa cell lines, and it was selected for further validation and analysis.

**Usp12 Stabilizes AR at the Protein Level—**Ubiquitination of AR causes a change in AR activity and stability and impacts both survival and growth of PCa cells, as a result deubiquitination of those sites has an equally important role. We hypothesized that Usp12 affects AR activity by deubiquitinating it and as a result stabilizing AR protein. To determine the effects of Usp12 on AR activity and protein stability we analyzed the levels of endogenous AR in PCa cells depleted of Usp12. Silencing of Usp12 resulted in a decrease of AR protein compared with SCR in three PCa cell lines (Fig. 2, A–C). Stabilization of AR by Usp12 relies on enzymatic activity of this DUB as mutant Usp12C48A was not able to stabilize AR protein levels to the same extent as the wild type (Fig. 2D). Additionally as little as 1:10 of Usp12 (50 ng) to AR (500 ng) was sufficient to cause this effect (Fig. 2D). Similarly, when HEK293T cells were transfected with AR and co-transfected with Usp12, Uaf-1, and WDR20 the levels of AR increased compared with AR alone (Fig. 2E). Even the increase in AR protein levels observed in cells transfected with Uaf-1 and WDR20 can be attributed to the stabilization of endogenous Usp12 caused by the overexpression of its cofactors as illustrated by Usp12 protein levels (Fig. 2E). To assess whether reduced receptor levels were a consequence of compromised AR gene expression we analyzed AR transcript level in LNCaP cells depleted of Usp12. Knockdown of Usp12 or either one of its interacting partners had no statistically significant effect on AR transcript levels suggesting that Usp12 may function to enhance the stability of the AR in PCa cells (data not shown). Additionally, we investigated the effects of Usp12 depletion on AR half-life in PCa cells. In cells with depleted Usp12 the pool of AR was smaller than in controls even before the cycloheximide treatment and there was a trend of decreased half-life of AR (Fig. 2F). In conclusion we have shown that Usp12, with its interacting partners Uaf-1 and WDR20, increases AR protein levels rather than regulating its gene expression.

**AR Stabilization by Usp12 Results in Increased AR Activity—**To assess the effects of increased AR protein stability HEK293T cells were transfected with an androgen-responsive luciferase reporter containing three adjacent androgen-responsive elements (AREs) upstream from the *luciferase* gene. Additionally, combinations of mammalian expression vectors including dual FLAG-AR, FLAG-Usp12, and FLAG-Uaf-1 were co-transfected, and receptor activity was assessed. Cells transfected with Usp12 showed a trend of increased AR transcriptional activity which was not statistically significant (Fig. 3A); however, when Usp12 and Uaf-1 were co-transfected, AR transcriptional activity was significantly increased to levels comparable with that caused by the known AR co-regulator p300 (Fig. 3A). This result is in agreement with previous reports that Usp12 requires the presence of Uaf-1 for its enzymatic activity (27). To confirm a transcriptional co-regulatory role of Usp12 in the AR signaling cascade, we assessed AR activity upon depletion of Usp12 in the LNCaP variant cell line, LNCaP-7B7, which have a
Usp12 Is a Novel Positive Regulator of the AR

Stabilization of AR by Usp12 Affects Survival and Proliferation of Prostate Cells—We have shown that Usp12 enhances AR activity by up-regulating receptor stability. We next assessed the role of Usp12 in regulating the survival and proliferation of PCa cell lines. Proliferation of three PCa cell lines was quantified by cell counting 96 h after Usp12 depletion. It was observed that Usp12 silencing caused a significant decrease in cellular proliferation in all three cell lines (Fig. 4A). To examine the impact of Usp12 knockdown on LNCaP cell survival, we measured apoptosis by annexin V staining by flow cytometry. Silencing of the Usp12 complex and Usp12 alone resulted in a significant increase of apoptotic cells that was comparable with the value obtained for cells with depleted AR (Fig. 4B).

Cell cycle analysis by PI staining revealed that depletion of the Usp12 complex results in a significant increase of G1-arrested PCa cells (Fig. 4C). Additionally, silencing of the Usp12 complex significantly increased the number of cells in sub-G1 phase, confirming that it causes an increase in cellular apoptosis (Fig. 4D).

One of the crucial properties of cancer cells is their ability to form colonies which allows for cancer survival. We evaluated the ability of LNCaP cells to form colonies after depletion of Usp12. Cells with silenced Usp12 had a significantly decreased ability to form colonies compared with SCR-treated control (Fig. 4E). In conclusion, we have shown that AR stabilization by Usp12 has a significant effect on proliferation and survival of PCa cells. Usp12 is pro-proliferative, and cells deficient in it have decreased ability to proliferate, have increased apoptosis and G1 arrest, and are deficient in their ability to form colonies. These data suggest that Usp12 has a key role in PCa disease progression.

Usp12 Interacts with AR and Stabilizes It via Deubiquitination—We have shown that Usp12 stabilizes AR at the protein level and as a result increases transcriptional activity acting in a pro-survival manner in prostate cells. To determine whether Usp12 interacts with AR we immunoprecipitated AR and its interacting partners from the whole cell lysate. These immunoprecipitants were immunoblotted for the presence of Usp12. Both wild type Usp12 and its Cys-48 catalytically deficient mutant Usp12C48A were shown to interact directly with AR (Fig. 5A). Additionally, we confirmed the interaction between the endogenous AR and Usp12 proteins in LNCaP PCa cells (Fig. 5B). To determine whether this interaction affects the AR ubiquitination status we transfected COS-7 cells with ubiquitin, AR, and wild type and the deubiquitase-dead C48A mutant Usp12. Cells were treated with proteosomal inhibitors and lysed under denaturing conditions which ensures that only covalent bonds will remain unaffected, and as a result only direct ubiquitination of the AR rather than its interacting partners can be visualized. Lysates were subsequently immunoprecipitated using an anti-ubiquitin antibody which allowed separation of all directly ubiquitinated proteins and the levels of ubiquitinated AR visualized by immunoblotting the precipitant (Fig. 5B). To determine whether this interaction affects the AR ubiquitination status we transfected COS-7 cells with ubiquitin, AR, and wild type and the deubiquitine-sead C48A mutant Usp12. Cells were treated with proteosomal inhibitors and lysed under denaturing conditions which ensures that only covalent bonds will remain unaffected, and as a result only direct ubiquitination of the AR rather than its interacting partners can be visualized. Lysates were subsequently immunoprecipitated using an anti-ubiquitin antibody which allowed separation of all directly ubiquitinated proteins and the levels of ubiquitinated AR visualized by immunoblotting the precipitant for AR protein. Wild type but not Cys-48-deficient mutant of Usp12 caused deubiquitination of AR (Fig. 5C).

To assess potential co-localization of the AR and Usp12 both proteins were ectopically expressed in COS-7 cells. Immuno-

![FIGURE 2. Usp12 stabilizes AR at the protein level. A–C, LNCaP, LNCaP-AI, and VCaP cells, respectively, were treated with siRNA as indicated. LNCaP and VCaP cells were cultured in full media and LNCaP-AI in DCC. At 96 h cells were lysed followed by immunoblotting. D, COS-7 cells were transfected with 500 ng of PFLAG-His-AR and increasing amounts (10–500 ng) of wild type and C48A mutant Usp12 for 48 h. Reactions were balanced with empty pcMV vector. E, HEK293T cells were transfected with pFLAG-His-AR, pFLAG-Usp12, pFLAG-Uaf-1, and pHAG-FLAG-WDR20 plasmids as indicated, and at 48 h cells were lysed followed by Western blotting. F, LNCaP cells were treated with siRNA as indicated for 96 h followed by treatment with 1 μM cycloheximide for 0–4 h.](image)
fluorescence and confocal microscopy were employed to visualize their cellular localization. It was observed that Usp12 and AR co-localize in the cytoplasm in steroid-depleted conditions (Fig. 5D). We have shown that enhanced levels of Usp12 result in increased AR protein stability and transcriptional activity. To confirm whether this increase in Usp12 can be observed in vivo we analyzed Usp12 positivity in benign and PCa patient samples. Usp12 protein levels were increased in PCa samples compared with benign controls (Fig. 5E). To summarize, AR and Usp12 interact, and enzymatically functional Cys-48 of Usp12 is not required for this interaction. Usp12 deubiquitinates AR through this interaction and for this intact Cys-48 of Usp12 is required, as a result AR is stabilized at the protein level and its transcriptional activity is enhanced resulting in the activation of pro-survival pathways in prostate cells.

DISCUSSION

It is widely accepted that the post-translational regulation of AR protein stability is a crucial mechanism that regulates both normal and malignant prostate cells. Even in CRPCa AR still plays a major role and remains the main focus of therapeutic strategies, highlighting its importance as a drug target. Therapies aimed at AR invariably fail as a result of AR becoming promiscuous through mutations and acquiring the ability to become acti-
Usp12 is a novel positive regulator of the AR

Our study identified Usp12 as a novel positive regulator of AR through an siRNA screen of DUBs. Usp12 was initially identified as a histone H2B and H2A deubiquitinase (25, 23); recently, it was also reported to be a negative regulator of Notch signaling by impairing Notch trafficking and decreasing its cell surface levels (24). Still little is known about the role of Usp12 in humans, but the role of the Usp12 homologue in yeast has been researched in more detail with the enzyme shown to be involved in actin dynamics, cell polarity, and endocytosis (28). In S. pombe, silencing of the Usp12 homologue in combination with Myosin-1 or Wiskott-Aldrich Syndrome protein (WAS) was reported to be lethal. Our data also point to the importance of Usp12 in cell survival as Usp12 depletion significantly increased the percentage of apoptotic cells and caused G1 arrest in PCA cells, suggesting an evolutionarily conserved role of Usp12 in cell survival.

Usp12 DUB activity was previously shown to be very low in the absence of its binding partners, WD40 proteins Uaf-1 and WDR20 (27). Our reporter gene assays confirm this role of Uaf-1, and we have shown that without Uaf-1, Usp12 was not able to increase AR transcriptional activity whereas Usp12 knockdown alone was sufficient to decrease it. This confirms the role that Uaf-1 plays in regulating the activity of Usp12. In S.
pombe, binding partners were shown to be necessary not only for DUB activity but also to affect cellular localization of Usp12. Uaf-1 deletion traps Usp12 in the nucleus, and analogously WDR20 deletion traps Usp12 in the cytoplasm (28). It remains to be established whether their role in Usp12 localization is conserved in human.

DUBs have been previously shown to affect AR stability. Usp10 is reported to bind to AR and positively regulate its tran-

**FIGURE 5.** Usp12 interacts with AR resulting in AR deubiquitination and AR stabilization. A, HEK293T cells were transfected with plasmids as indicated, wild type (Usp12) and Cys-48-deficient mutant (Usp12M) of Usp12 were used. 48 h after transfection cells were harvested and lysates were immunoprecipitated (IP) with 1 μg of AR antibody followed by immunoblotting. B, LNCaP cells were harvested, and lysates were immunoprecipitated for AR and with a nonspecific IgG. C, COS-7 cells were transfected with plasmids as indicated, and wild type (Usp12) and Cys-48-deficient mutant (Usp12M) of Usp12 were used. 72 h after transfection cells were treated with MG132 and harvested 16 h later. Lysates were denatured and subsequently immunoprecipitated with 1 μg of ubiquitin antibody followed by immunoblotting. D, COS-7 cells were grown in steroid-depleted medium and transfected with equal amounts of Usp12-FLAG and AR plasmids. 48 h after transfection cells were fixed, and immunofluorescence followed by confocal microscopy were used to visualize the cellular localization of both proteins. DAPI was used as a nuclear stain. Scale bars, 20 μm. E, Usp12 immunohistochemistry of PCa and benign patient samples are shown. Images are representatives of n = 7 for each group. Scale bar, 50 μm.
scriptional activity (22). Recently, Usp10 effects on AR were proposed to be indirect via Usp10-mediated deubiquitination of H2A.Z leading to transcriptional activation of AR (35). This hypothesis requires further investigation in the context of Usp12 as it was also shown to deubiquitinate histones H2A and H2B (23). It is possible that the Usp12 effect on AR could be a combination of both direct deubiquitination and stabilization of the receptor and indirect regulation through deubiquitination of histones which allows transcriptional activation. Similarly, Usp26 is reported to assemble with AR and additional cofactors in subnuclear foci resulting in AR deubiquitination (21). We have also observed that Usp12 and AR co-localize and interact, resulting in deubiquitination of AR. Co-localization of AR and Usp12 occurs in the cytoplasm which can be explained by the large portion of the proteasome being present in the cytoplasm; it is also possible that for their co-localization in the nucleus additional Usp12 cofactors would need to be co-transported to facilitate its shuttling similarly to what was observed in S. pombe. This causes stabilization of AR at a protein level. It has been previously published that silencing of AR results in G1 arrest and increased apoptosis; interestingly, we have observed that Usp12 silencing has the same effects on PCa cells. These cellular effects might be mediated by a combination of both AR-mediated and AR-unrelated effects. AR stabilization by Usp12 enhances transcriptional activity of AR and as a result increases cellular proliferation. We report that Usp12 acts in a pro-proliferative manner in PCa cells, which suggests that Usp12 may play a crucial role in prostate cancer development, progression, and metastasis. It remains to be established whether mutations in Usp12 are associated with PCa occurrence and progression. Detailed impact of Usp12 in PCa and its potential as a therapeutic target needs further assessment in the future.

Acknowledgments—We thank Prof. A. D’Andrea for Uaf-1 and WDR20 plasmids and Claudia A. Ryan-Munden for technical expertise.
