Abstract

BiFeO₃-BaTiO₃ (BF-BT) is a promising high temperature lead-free piezoceramics due to their excellent piezoelectric properties with high Curie temperature ($T_c$>500 °C). While the high leakage current density severely restricted its application. In this work, the leakage mechanism relative to the dielectric properties and piezoelectric properties were systematically studied with a special emphasis on gallium (Ga³⁺) adding effect in 0.7BiFe(1-x)GaₓO₃-0.3BaTiO₃ (BFGax-BT, 0≤x≤0.10) ceramics. A high resistivity ($\rho$) of 2.73×10¹² Ω·cm⁻¹ and low leakage current ($J$) of 7.78×10⁻⁹ A·cm⁻² were achieved at $x$=0.06, which attributes to the low oxygen vacancies ($O^\leftrightarrow\text{V}_\text{O}$). The $J$-$E$ curves reveal different type of conduction process in BFGax-BT ceramics, including Ohmic conduction, space-charge-limited conduction (SCLC) mechanism and interface-limited Schottky emission. The BFGa0.06-BT ceramic exhibits excellent piezoelectric performance: $d_{33}$=174 pC·N⁻¹, $T_c$=497 °C, $k_p$=29 %.

1. Introduction

Lead-based Pb(Ti, Zr)O₃ (PZT) ceramics are primary commercial piezoelectric ceramics and widely used in sensors, brakes and transducers[1]. However, the application of lead-based piezoelectric ceramics is restricted by the toxicity of lead, which promotes the development of lead-free piezoelectric ceramics, such as BiFeO₃ (BF) [2-4], BaTiO₃ (BT) [5-6], Kₓ/2Na₁₋ₓ²NbO₃ (KNN) [7-9], Bi₁₋ₓ/2Na₁/₂TiO₃ (BNT) [10-11]. Among them, BF is a promising lead-free piezoelectric ceramic due to the large spontaneous polarization of 88-100 μC·cm⁻² and high Curie temperature ($T_C$) of 836 °C[2,4]. A continuous (1-x)BF-xBT solid solution with rhombohedral (R), pseudocubic (PC), and tetragonal (T) symmetries was formed at 0.00≤x≤0.33, 0.33≤x≤0.92 and 0.92≤x≤1[12], respectively, which reveals the potential of both superior piezoelectricity and a high $T_C$ in BF-BT system near the morphotropic phase boundary (MPB). Excellent $d_{33}$ (130-240 pC·N⁻¹) and large electric field-induced (E-induced) strains ($S$=0.2-0.3 %) with high $T_C$ (430-600 °C) were achieved in (1-x)BF-xBT ceramics at the MPB compositions of 0.25≤x≤0.35 [13-16].

However, the narrow synthesis temperature range and Bi volatilization during solid-state reaction produce the formation of Bi₂₅FeO₄₀ and Bi₂Fe₄O₉ phases and are obstacles for preparing pure (1-x)BF-xBT phase [16-18]. Besides, part of Fe³⁺ will transform into Fe²⁺ during calcining and sintering process. These factors all lead to the generation of a large amount of oxygen vacancies ($V_o^{**}$), resulting in a high leakage current ($J$) and a large dielectric loss, which is harmful for polarization and obtaining saturated $P$-$E$ hysteresis loop [19-20]. Lots of attempts on reducing $J$ and enhancing direct current resistivity ($\rho$) have been performed by optimizing preparation process and doping modification. Lee et al. inhibited the formation of secondary Bi₂Fe₄O₉ and/or Bi₂₅FeO₃₉ phases by water quenching method, whereby a low leakage current density of 7.5×10⁻¹⁰ A·cm⁻² and an excellent piezoelectric property of $d_{33}$=240 pC·N⁻¹ achieved in 0.67BF-0.33BT ceramics [21]. Using nano-BaTiO₃/Bi₂O₃/Fe₂O₃ as raw materials instead of
BaCO$_3$/TiO$_2$/Bi$_2$O$_3$/Fe$_2$O$_3$ to prepare BF-BT ceramics, Cheng et al. realized an increased $d_{33}=210$ pC·N$^{-1}$ from 164 pC·N$^{-1}$ in 0.7BF-0.3BT along with an order of magnitude improved insulation resistance [22]. Besides, the use of stability elements, like La, Ga, Bi(Zn$_{1/2}$Ti$_{1/2}$)O$_3$ and Nd etc., to replace A and/or B site of BF is also effective to enhance the electrical performance of (1-$\chi$)BF-$\chi$BT ceramics [23-26]. It is reported that the water quenched BF-33BT-3BiGaO$_3$ ceramic exhibited excellent piezoelectric properties $d_{33}=402$ pC·N$^{-1}$ with high $T_C=454$ °C, which attributes to the low $J=1\times10^{10}$ A·cm$^{-2}$ under the electric field of 50 kV·cm$^{-1}$ [21]. However, the water quenching process is difficult to commercialize for its poor repeatability. It is necessary to prepare excellent performance Ga-doped BF-BT using traditional methods. Zhou et al. realized good piezoelectric properties: $d_{33}=157$ pC·N$^{-1}$, $k_p=0.326$, and $T_C=464$ °C in 0.7Bi(Fe$_{1-x}$Ga$_x$)O$_3$-0.29BT ceramics at $x=0.015$ [27]. But the leakage conduction mechanism of Ga-doped BF-BT ceramics is still unclear, and needs to investigate thoroughly. In this work, the 0.7BiFe$_{1-x}$Ga$_x$O$_3$-0.3BaTiO$_3$ (BFGa$_x$-BT, 0$\leq x \leq$0.10) ceramics near the MPB were prepared by conventional solid sintering method, the leakage mechanism evolution, dielectric properties and piezoelectric properties were systematically studied. Benefitted to the suppressed valence of Fe$^{3+}$ and V$^{1+}_{01}$ by Ga-doping, the BFGa0.06-BT ceramic exhibits excellent piezoelectric performance: $d_{33}=174$ pC·N$^{-1}$, $T_C=497$ °C, $k_p=29$ %, along with a high $\rho=2.73\times10^{12}$ Ω·cm$^{-1}$ and low $J=7.78\times10^9$ A·cm$^{-2}$.

2 Experimental section

The conventional solid-state reaction method was used to prepare the 0.7BiFe$_{(1-x)}$Ga$_x$O$_3$-0.3BaTiO$_3$ (0$\leq x \leq$0.10) (BFGax-BT) ceramics using Fe$_2$O$_3$, Bi$_2$O$_3$, (>99 %, both from Shantou Xilong Chemical Factory Guangdong, China), nano-particle BT (>99.9 %, from Aladdin, C-phase) and Ga$_2$O$_3$(>99.99 %, from Aladdin). These raw materials were weighed according to the chemical formula, and then mixed thoroughly in ethanol for 24 h by using a planetary ball mill. After calcining the mixtures at 800 °C for 6 h, the powders
were re-milled, and then pressed into pellets of 10 mm in diameter and 1 mm in thickness under 80 MPa
with 2 wt% polyvinyl alcohol (PVA). After excluding binder at 650 °C for 2 h, the pressed pellets were
sintered at 980 °C for 3 h with the heating rate of 5 °C·min⁻¹. The sintered specimens were pasted with silver
on both surface and fired at 600 °C for 20 min, then poled under a DC field of 3.5 kV at 100 °C for 10 min in
a silicone oil bath.

The X-ray diffraction (XRD) with Cu $K_a$ radiation (D/max-RB, Rigaku Inc., Japan) was used to
examine crystalline structure of the sintered samples. Rietveld refinement was performed by using Materials
studio software. The microstructure of the sintered samples was observed using field emission scanning
electron microscopy (FESEM, SUPRATM 55, Japan). Bulk density was measured by using the Archimedes’
method. The powders chemical state of the prepared ceramics was characterized by X-ray photoelectron
spectroscopy (XPS: Thermo Fisher ESCALAB 250Xi) using Al $K_a$ radiation ($h\nu = 1486.6$ eV) as an X-ray
source. Dielectric properties were measured using a programmable furnace with a LCR analyzer (TH2828S)
at 100 kHz in temperature range of 25 °C to 600 °C. The piezoelectric properties were measured using a
quasi-static piezoelectric coefficient testing meter (ZJ-3A, Institute of Acoustics, Chinese Academy of
science, Beijing, China). The $k_p$ and the mechanical quality factor ($Q_m$) were determined by
resonance-antiresonance method using an Agilent 4294A precision impedance analyzer (Hewlett-Packard,
Palo Alto, CA). The $J$ and $\rho$ was measured by AT683 insulation test instrument (Applent instruments Ltd,
China). A ferroelectric measuring equipment (aixACCT TF Analyzer 1000, Germany) was used to obtain the
ferroelectric hysteresis ($P-E$) loops and field-induced strain ($S-E$) loops.

3 Results and discussion

Fig. 1a-b shows the $\rho$-$E$ and $J$-$E$ curves of poled BFGax-BT ceramics measured at room temperature (RT). The $\rho$ of all samples rapidly decreases with $E$ increasing at $E \leq 8$ kV·cm⁻¹. When $E > 8$ kV·cm⁻¹, the $\rho$ of
0 ≤ x ≤ 0.02 still decreases, while that of 0.04 ≤ x ≤ 0.1 hold steady. The ρ of x=0.06 is around 2.73×10^{12} \text{Ω} \cdot \text{cm}^{-1} under E=12 \text{kV} \cdot \text{cm}^{-1}, which is larger than that of BF-BT (0.55×10^{12} \text{Ω} \cdot \text{cm}^{-1}), indicating an effectively enhanced the insulation of BF-BT ceramics via Ga-doping. The J of BFGax-BT ceramics shows a different trend, which increases with E increasing.

![Fig. 1 ρ-E (a) and J-E (b) of BFGaₓ-BT ceramics measured at room temperature.](image)

According to the previous reported transport behavior of BiFeO₃ and other similar ferroelectric perovskite oxides [20,28-32], the relationship between the leakage current (J) and the applied electric field (E) for Ohmic conduction, space-charge-limited conduction (SCLC) mechanism and interface-limited Schottky emission are expressed as in Eq. (1-3) as follow:

\[
J_{\text{Ohmic}} = e \mu N_e E
\]

(1)

Where e is the electron charge, \( \mu \) is the free carrier mobility, \( N_e \) is the density of the thermally stimulated electrons.

\[
J_{\text{SCLC}} = \frac{9}{8} \varepsilon_r \varepsilon_0 \mu \theta \frac{E^2}{d}
\]

(2)
Where $\varepsilon_r$ is the static dielectric constant, $\varepsilon_0$ is the permittivity of free space, $\mu$ is the free carrier mobility, $d$ is the thickness of thin film, and $\theta$ is the ratio of the total density of free electrons to the trapped electrons.

$$J_{\text{Schottky}} = A T^2 \exp\left[ \frac{\varphi_b}{k_B T} - \frac{e}{k_B T} \left( \frac{eE}{4\pi \varepsilon_0 K} \right)^{1/2} \right]$$

(3)

Where $A$ is constant, $T$ is absolute temperature, $\varphi_b$ is the voltage barrier, $k_B$ is the Boltzmann constant, $e$ is the electron charge, $\varepsilon_0$ is the permittivity of free space and $K$ is the optical dielectric. It is clearly according to Eqs. (1-2) that the $\ln(J)$ is proportional to $\ln(E)$ for Ohmic conduction and SCLC mechanism, whose slope ($S$) of $\ln(J)$-$\ln(E)$ is 1 or 2, respectively. While the $\ln(J)$ is proportional to $E^{1/2}$ in Eq. (3), suggesting the interface-limited Schottky emission conduction mechanism.

The curves of $\ln(J)$-$\ln(E)$ for BFGax-BT ceramics in Fig. 2a follow a nearly linear behavior with $S=1.91$ at $x=0$, indicating a dominant SCLC mechanism. However, the curve of $x=0.02$ in Fig. 2b can be well fitted by two straight lines: the $S=1.22$ at $E \leq 3 \text{kV} \cdot \text{cm}^{-1}$ corresponds to Ohmic conduction; The $S=2.43$ at $E > 3 \text{kV} \cdot \text{cm}^{-1}$ indicates a dominant SCLC mechanism which results from the electrons injects into the insulator at high electric field [20,28-32]. As $x$ increases to 0.04, the $\ln(J)$-$\ln(E)$ plot in Fig. 2c shows a linear behavior with $S=1.12$, suggesting that the leakage mechanisms transform to a pure Ohmic conduction. When $0.06 \leq x \leq 0.1$ at $E \leq 8 \text{kV} \cdot \text{cm}^{-1}$, the $\ln(J)$-$\ln(E)$ plots in Fig. 2d-f show a nonlinear behavior, thus single Ohmic conduction and SCLC mechanism can be ruled out. In order to confirm the leakage mechanism in this region, the $\ln(J)$-$E^{1/2}$ curves for $0.06 \leq x \leq 0.1$ are plotted in Fig. 2g. It is seen that the curves show obvious linear characteristic, suggesting the Schottky emission mechanism dominates according to Eq. 3. The same conduction mechanism was reported in Bi$_{0.9}$La$_{0.1}$FeO$_3$ at low applied electric field [31]. When $E > 8 \text{kV} \cdot \text{cm}^{-1}$, the $S$ of $0.06 \leq x \leq 0.1$ in Fig. 2d-f is 0.92, 0.85 and 1.04, respectively, which correspond to Ohmic conduction. The slopes for $\ln(J)$-$\ln(E)$ and $\ln(J)$-$E^{1/2}$ are plotted in Fig. 2h, which exhibit the leakage mechanism transformation.
Fig. 2 ln(J)-ln(E) of BFGa-x-BT ceramics: (a) x=0, (b) x=0.02, (c) x=0.04, (d) x=0.06, (e) x=0.08, (f) x=0.1; (g) ln(J)-E^{1/2} for BFGa-x-BT ceramics at x=0.06, 0.08 and 0.1; (h) x-dependence of Slope.

It is well known that the Bi^{3+} volatilization and the valence change of Fe^{3+}→Fe^{2+} usually happened in BF ceramics, both of them could generate \( V_0^{\bullet\bullet} \) corresponding to the \( V_{O_1}^{\bullet\bullet} \) and \( V_{O_2}^{\bullet\bullet} \) respectively, causing a high \( J \), as shown in eqs. 4-5 [33-35].

\[
2\text{BiFeO}_3 \xrightarrow{\Delta 830^\circ C} \text{Bi}_2\text{O}_3 + \text{Fe}_x^{\bullet\bullet} + 3\text{O}_x^{\bullet\bullet} + 2V_{\text{Bi}}^{\bullet\bullet} + 3V_{O_1}^{\bullet\bullet} \\
2\text{Fe}_\text{Fe}^{\bullet\bullet} + \text{O}_\text{O}^{\bullet\bullet} \rightarrow \text{Fe}_\text{Fe}^{\bullet\bullet} + V_{O_2}^{\bullet\bullet} + \frac{1}{2}\text{O}_2 
\]

In order to analysis the valence of the constituent elements, high resolution XPS spectral analyses were performed for BFGax-BT ceramics. The relative percent of Fe^{3+} and O_i for BFGa-x-BT ceramics as a function of \( x \) are shown in Fig. 3a, along with the \( \rho \) at 12 kV·cm\(^{-1}\). The detailed information of Bi 4f, Ba 3d, Ti 2p Fe
2p and O 1s can be seen in Fig. S1. It was found in Fig S1a that the Bi³⁺ volatilization is independent of x, because all samples were calcined and sintered at the same temperature. The Fe 2p peaks in Fig. S1d are broad and asymmetric, suggesting the coexistence of Fe³⁺ and Fe²⁺, which subdivided into 2p₃/2 and 2p₁/₂ of Fe³⁺ and Fe²⁺. The fitting results of Fe 2p peaks for BFGax-BT ceramics (0≤x≤0.08) by XPSPEAK41 software are illustrated in Fig. S2a-e. After peak fitting, the relative percentages of Fe³⁺ (Fe³⁺(%)) and Fe²⁺ (Fe²⁺(%)) were calculated from peak areas using equation

\[ \text{Fe}^{3+}(\%) = \frac{A_1 + A_2}{A_1 + A_2 + A_3 + A_4} \]

where A1, A2, A3 and A4 indicate the area of Fe³⁺ 2p₃/2, Fe³⁺ 2p₁/₂, Fe²⁺ 2p₃/2 and Fe²⁺ 2p₁/₂ near 710.9 eV, 724.5 eV, 710.0 eV and 723.5 eV, respectively. The fitting results of O 1s are shown in Fig. S3 by similar peak fitting and calculation process. The Fe³⁺(%) in Fig. 3a increases from 83 % to 89 % as x increases from 0 to 0.06, then decreases to 86 % at x=0.10. The O₁ and ρ show the same trend as Fe³⁺, which increase first and then decreases with x increasing as shown in Fig. 3a. The maximum of O₁ and ρ are achieved at x=0.06, which is 63 % and 2.73×10¹² Ω·cm⁻¹. It is reasonable that Ga-doping will reduce \( V_{O₁}^{**} \) derived from the valence of Fe, leading to the different leakage mechanism, which is benefited for improving ρ.

Fig. 3b-c illustrates temperature dependence of \( tan\delta \) and \( \varepsilon_r \) for BFGax-BT ceramics measured at 100 kHz from RT to 600 °C. The values of \( tan\delta \) for x=0.02 start to rise at 300 °C, while the others remain relatively low until 350 °C. The highest \( tan\delta \) at all testing temperatures is observed at x=0.02 due to the highest \( V_{O₁}^{**} \) content [36]. \( \varepsilon_r \) of all ceramics in Fig. 3c appears a peak corresponding to the Cure phase transition temperature. The \( T_C \) value firstly increases from 500 °C to 523 °C as x increases from 0 to 0.04, then decreases to 484 °C at x=0.08, indicating BFGax-BT ceramics are promising piezoelectric materials for high-temperature application. Besides, a clearly relaxor-like behavior with wide phase transition temperature is detected at x=0.1. Combining with the XRD and Rietveld results in Fig. S4-S5 and Table S1, it is obvious the variation with x of both \( T_C \) and R phase fraction in Fig. 3d shows a good correction, which suggests the more R phase, the higher \( T_C \).
Fig. 3 (a) $x$-dependence of the relative percentage of Fe$^{3+}$ and O$^-$ for BFGa$_x$-BT ceramics, along with the $\rho$ at 12 kV·cm$^{-1}$; Temperature dependence of dielectric loss ($\tan\delta$) (b) and dielectric constant ($\varepsilon_r$) (c) measured at 100Hz for BFGa$_x$-BT ceramics; (d) The $x$-dependence of Curie temperature ($T_C$) and $R$ phase fraction.

Fig. 4a-c shows $P$-$E$ loops at RT, bipolar $S$-$E$ curves and unipolar $S$-$E$ curves measured at 50 kV·cm$^{-1}$ and 1 Hz for BFGa$_x$-BT ceramics, and the maximum polarization ($P_m$), remanent polarization ($P_r$), coercive field ($E_C$), bias electric field ($E_i$), positive strain ($S_{\text{pos}}$), negative strain ($S_{\text{neg}}$), unipolar strain ($S_{\text{uni}}$) and $\Delta P^2$ (the square of polarization difference, $P_m^2-P_r^2$) as a function of $x$ are summarized in Fig. 4d-f. All BFGa$_x$-BT ceramics exhibit saturated $P$-$E$ loops and butterfly $S$-$E$ curves. As $x$ increasing, the $E_i$ in Fig. 4d increases firstly and then decreases. The maximum $E_i$ is shown at $x=0.02$, indicating the existence of lots of defect-dipole, which results in the largest $P_m=28.7 \mu$C·cm$^{-2}$ and $P_r=23.4 \mu$C·cm$^{-2}$ because of the free point defects will be oriented under electric field. As $x\geq0.8$, the structure is far from the appreciate phase fraction,
which causes the decreased \( P_r \) and \( P_m \). Fig. 4e shows the \( x \)-dependence of \( S_{\text{pos}} \) and \( S_{\text{neg}} \) for BFGax-BT ceramics. \( S_{\text{pos}} \) is a sum of intrinsic piezoelectric lattice strain and extrinsic reversible domain switching strain, while \( S_{\text{neg}} \) involves the non-180° domain reorientation [38-39]. The increased \( S_{\text{pos}}=0.14 \% \) and \( S_{\text{neg}}=-0.06 \% \) at \( x=0.08 \) caused by the increased \( PC \) phase results in the raise of distortion, which is consistent with the change of phase fraction. However, the structure of BFGax-BT ceramics turns to single phase fraction at \( x=0.10 \), which lead to the decrease of \( S_{\text{pos}} \) and \( S_{\text{neg}} \). It is reported that the relationship between field-induced strain (\( S \)) and the polarization (\( P \)) usually written as \( S=Q\Delta P^2 \), where \( Q \) represents the electrostrictive coefficient [40-42]. The \( x \)-dependence of \( S_{\text{uni}} \) and \( \Delta P^2 \) are contrasted in Fig. 4f, exhibiting exactly the same traces that the maximum value \( \Delta P^2 =347 \ \mu \text{C}^2\cdot\text{cm}^{-4} \) and \( S_{\text{uni}}=0.14 \% \) are achieved at \( x=0.08 \). Thus, the unipolar strain behavior in this work is attributed to the constant values of \( \Delta P^2 \).

\[ \text{Fig. 4 (a) Bipolar } P-E \text{ hysteresis loops, (b) bipolar } S-E \text{ loops, and (c) unipolar } S-E \text{ loops for BFGax-BT ceramics; } P_m, P_r, E_C \text{ and } E_i \text{ (d), } S_{\text{pos}} \text{ and } S_{\text{neg}} \text{ (e), } \Delta P^2 \text{ and } S_{\text{uni}} \text{ (f) as a function of } x. \]

Fig. 5 illustrates the \( x \)-dependence of \( d_{33}, k_p \) and \( Q_m \) for BFGax-BT ceramics. The values of \( d_{33} \) and \( k_p \) firstly increase and then decrease as \( x \) increases. \( Q_m \) has little variation between 25 and 29 with \( x \) apart from the trend of \( d_{33} \) and \( k_p \). The highest \( d_{33}=174 \ \text{pC}\cdot\text{N}^{-1} \) and \( k_p=29 \% \) are achieved at \( x=0.06 \), along with a high
$T_c=497 \, ^\circ C$ because of the synergistic effect of appropriate MPB, high relative density and low $J$, as shown in Fig. S4-S6 and Fig. 1. Although they are inferior to piezoelectric properties $d_{33}=402 \, pC\cdot N^{-1}$, $T_c=454 \, ^\circ C$ obtained in the water quenched BF-33BT-3BiGaO$_3$ ceramic, $d_{33}$ and $k_p$ are obviously superior to the value reported in BFGax-BT ceramics prepared by solid solution method.

![Piezoelectric coefficient ($d_{33}$), electromechanical coupling factors ($k_p$), $Q_m$ as a function of $x$ for BFGax-BT ceramics.](image)

**4 Conclusions**

0.7BiFe$_{1-x}$Ga$_x$O$_3$-0.3BaTiO$_3$ (BFGax-BT, 0≤$x$≤0.10) ceramics were prepared by the conventional solid state reaction method. The valence of Fe$^{3+}$ and $V_{0i}^{\star}$ were suppressed by Ga-doping, resulting in the increased $\rho$ and decreased $J$. The highest Fe$^{3+}$ (89%) content with high $\rho=2.73\times10^{12} \, \Omega\cdot cm^{-1}$ and low $J=7.78\times10^{-9} \, A\cdot cm^{-2}$ under 12 kV·cm$^{-1}$ were obtained at $x=0.06$. The $J$-$E$ curves reveal the different type of conduction process in BFGax-BT ceramics. As $x$ increases, the leakage conduction mechanism changes from SCLC mechanism at $x=0$ into Ohmic conduction at $x=0.04$. Both of the Schottky emission and Ohmic conduction are existed in 0.06≤$x$≤0.10. Due to the suitable MPB, high relative density and low $J$, the highest piezoelectric properties $d_{33}=174 \, pC\cdot N^{-1}$ and $k_p=29 \%$ with a high $T_c=497 \, ^\circ C$ were achieved at $x=0.06$, indicating the BFGax-BT system has a promising prospect in high temperature piezoelectric devices.
